2. *Arbutoideae*.—Fruit a berry or capsule, petals deciduous and anthers with bristle-like appendages, chiefly north temperate to arctic in distribution. *Arbutus Unedo*, the strawberry-tree, so-called from its large scarlet berry, is southern European extending into south Ireland. *Arctostaphylos* (bearberry) and *Andromeda* are arctic and alpine genera occurring in Britain and also extending from the arctic into the mountainous regions of northern United States. *Epigaea repens* is the trailing arbutus or mayflower of Atlantic America.

3. *Vaccinioideae*.—Ovary inferior, fruit a berry. Extends from the north temperate zone to the mountains of the tropics. *Vaccinium*, the largest genus, has three British species: *V. Myrtillus* is the bilberry (*q.v.*), blueberry or whortleberry, *V. Vitis-Idaea* the cowberry, and *V. Oxycoccos* the cranberry (*q.v.*). There are 20 species recognized in the United States.

4. *Ericoideae*.—Fruit usually a capsule, seeds round, not winged; corolla persisting round the ripe fruit; anthers often appendaged. The largest genus is *Erica*, the true heath (*q.v.*), with 500 species, the majority confined to the Cape; others occur on the mountains of tropical Africa and in Europe and north Africa, especially the Mediterranean region. *E. cinerea* (purple heather) and *E. Tetralix* (cross-leaved heath) are common British heaths. *Calluna* is the ling or Scotch heather. The genus is not represented in the United States.

ERICHSEN, SIR JOHN ERIC, BART. (1818–1896), British surgeon, born on July 19, 1818, at Copenhagen, was the son of Eric Erichsen, a member of a well known Danish family. He studied medicine at University college, London, and in Paris, and lectured on general anatomy and physiology at University college hospital. In 1848 he was appointed assistant surgeon at University college hospital, in 1850 became full surgeon and professor of surgery, and in 1875 he joined the consulting staff. His *Science and Art of Surgery* (1853) went through many editions. He was created a baronet in 1895, having been for some years surgeon-extraordinary to Queen Victoria. As a surgeon his reputation was world wide. He died at Folkestone on Sept. 23, 1896.

ERICSSON, JOHN (1803–1889), Swedish-American naval engineer, was born at Langbanshyttan, Wermland, Sweden, on July 31, 1803. Showing from his earliest years a strong mechanical bent, young Ericsson, at the age of 12, was employed as a draughtsman by the Swedish Canal Company. From 1820 to 1827 he served in the army, where his drawing and military maps attracted the attention of the king, and he soon attained the rank of captain. In 1826 he went to London, at first on leave of absence from his regiment, and in partnership with John Braithwaite constructed the "Novelty," a locomotive engine for the Liverpool and Manchester railway competition at Rainhill in 1829, when the prize, however, was won by Stephenson's "Rocket." The number of Ericsson's inventions at this period was very great. Among other things he worked out a plan for marine engines placed entirely below the water-line. Such engines were made for the "Victory," for Captain (afterwards Sir) John Ross's voyage to the Arctic regions in 1829, but they did not prove satisfactory. In 1833 his caloric engine was made public.

In 1836 he took out a patent for a screw-propeller, and though the priority of his invention could not be maintained, he was afterwards awarded a one-fifth share of the £20,000 given by the Admiralty for it. At this time Capt. Stockton, of the U.S. Navy, gave an order for a small iron vessel to be built by Laird of Birkenhead, and to be fitted by Ericsson with engines and screw. This vessel reached New York in May 1839. A few months later

Ericsson followed his steamer to New York, and there he resided for the rest of his life, establishing himself as an engineer and a builder of iron ships. In 1848 he was naturalized as a citizen of the United States. Defensive armour for ships of war had long occupied his attention, and he had constructed plans and a model of a vessel lying low in the water, carrying one heavy gun in a circular turret mounted on a turn-table. In 1854 he sent his plans to the French emperor, Louis Napoleon, who declined to use them.

During the American Civil War, the Navy department invited proposals for the construction of armoured ships. Ericsson's design was accepted and the first armoured turret ship, the "Monitor," was launched on Jan. 30, 1862. On March 9, she fought the celebrated action with the Confederate ram "Merrimac." The peculiar circumstances in which she was built, the great importance of the battle, and the decisive nature of the result gave the "Monitor" an exaggerated reputation, which further experience did not confirm. In later years Ericsson devoted himself to the study of torpedoes and sun motors. He published *Solar Investigations* (1875) and *Contributions to the Centennial Exhibition* (1877). He died in New York on March 8, 1889, and in the following year on the request of the Swedish government, his body was sent to Stockholm and thence into Wermland, where, at Filipstad, it was buried on Sept. 15.

A *Life of Ericsson* by William Conant Church was published in New York in 1890 and in London in 1893.

ERIDANUS, in astronomy, a large constellation (*q.v.*) of the southern hemisphere, stretching from near Rigel at the heel of Orion (*q.v.*) to Achernar (α Eridani), not far from the South Polar Circle. α Eridani is the only star (*q.v.*) at present of the first magnitude in this constellation. The double star θ Eridani is now of the 3rd magnitude, but is identified with the *Achernar* (the shining one) of Al-Sufi who described it as of the first magnitude; it has therefore decreased considerably in brilliancy within historic times, and has thus surrendered its title of "the shining one" to α Eridani.

That o_2 Eridani is a ternary system was discovered by Herschel in 1783; it consists of a star of magnitude 4·5, associated with a close pair of about the 10th magnitude and 82″ distant from it.

Eridanus fluvius is the name under which the constellation appears in the catalogue of Tycho Brahe, Eridanus being a Greek river-god and also an ancient name for the river Po, in Italy. In the older catalogues it appeared simply as "the river" stars: *Stellae Fluminis*, according to Ulugh Beg, and the ἀστερισμὸς Ποταμοῦ according to Ptolemy who catalogued 34 stars in it.

ERIDU (modern Abu Shahrein) in 31° N. and 46° E., an ancient city of Mesopotamia. The report of Taylor's excavations in 1855 were the only source of information about this important city until R. Campbell Thompson carried out excavations in 1918. He found a long brick stamp of the eighth king of Larsa Nur-Adab, commemorating his work at Eridu, thus confirming Taylor's previous identification. The city was stated in ancient texts to be on the edge of the sea. This had been interpreted to mean the Persian gulf; Thompson found large quantities of fresh water mussels, but sea shells were also found and probably both were used for food (*see* MESOPOTAMIA: *Ancient Geography*). There was evidence of late stone age burials and early Kassite graves, but after the time of Hammurabi the city became of little importance, probably owing to the silting up of the lake. In ancient times Eridu was undoubtedly closely connected with Lagash, probably owing to water communications between the two cities. It was never the seat of a dynasty and did not even possess a Patesi—originally a position corresponding more or less to mediaeval "prince-bishop," but which later became the equivalent of a local governor of a dependent city state. It is possible however that in prehistoric times it may have occupied a more important position, and Hall has suggested that there may even have been at one time a Sumerian federation with its head either at Nippur or Eridu. In later times throughout the whole of Sumerian history there were two important schools of religious thought, one of them being associated with Eridu, and the other Nippur, Eridu being associated with the cult of Ea the earth god. From the geographical point of view the city is of special interest in its relation to the old sea line, and the evidence which it affords of the changes that have taken place in southern Mesopotamia since early times.

Hall, "Excavations at Ur, Eridu and El Obeid," *Proc. Soc. Antiquaries, 1919* (pp 22–44); S. Langdon, *Cambridge Ancient History*, Vol. i. (1923) with bibliography.

ERIE, a city of Pennsylvania, U.S.A., in the north-western corner of the State, on Lake Erie; a port of entry, the county-seat of Erie county, and an important manufacturing and commercial city. It is on Federal highways 6, 19 and 20; has an airport; and is served by the Bessemer and Lake Erie, the New York Central, the Nickel Plate, and the Pennsylvania railways, by motor-bus lines and an interurban electric railway and by lake steamers. The population in 1920, including the area annexed just after the Federal census was taken, was 102,093, of whom about 22% were foreign-born white (largely from Germany, Poland, Italy and Russia); and was estimated locally at 137,000 in 1928.

Erie has a fine harbour, protected from the severest storms by the peninsula of Presque Isle, a natural breakwall 11m. long and from 300ft. to 2·5m. across, and equipped with modern facilities for loading and unloading. The largest carriers on the Great Lakes can enter and leave the harbour without a tow. The city covers about 20 sq.m. of level ground, about 570ft. above sea-level. Most of the streets are 60 or 100ft. wide, and they cross at right angles. There are 18 municipal parks, with an aggregate area of 218ac.; and Presque Isle, with its 3200ac. of virgin forest, fine bathing beaches and excellent fishing, is a State park. East and west of the city for 12m., the lake shore is lined with summer homes and cottages. There is a municipal bathing pool, two municipal and two private golf courses, a community playhouse, a local symphony orchestra and a stadium which seats 15,000. Natural gas is used for domestic fuel. The city has a planning commission. In 1927 the assessed valuation of property was $142,468,828.

The manufacturing industries are large, numerous and diversified, with an output for the Erie district valued at $120,000,000 annually. The Erie works of the General Electric Company, occupying 300ac. and employing normally 6,500 persons, makes electric locomotives, railway motors, generators, transformers, air compressors and various kinds of equipment, castings and patterns. Other leading factory products are boilers, engines, tanks, wringers, precision tools, castings of all kinds, blast furnaces, stoves, asbestos products, silks, paper, aluminium utensils, hospital and sterilizing equipment, kitchen and laundry appliances, steam shovels and travelling cranes. The commerce of the port amounted in 1924 to 2,527,361 tons (valued at $44,839,382), consisting largely of incoming pulpwood from Canada, grain, flour, and iron ore from north-western ports, and shipments of coal (bituminous and anthracite) received by rail from the Pennsylvania, Ohio and West Virginia fields. The city ships by rail large quantities of grapes and other fruits, fish and manufactured products. Bank clearings in 1926 amounted to $429,618,517.

A United States Naval Reserve unit, stations of the Coast Guard Service and of the Weather bureau, a State armory, and a State fish hatchery are located at Erie. It is the headquarters of the State harbour and fish commission, and the seat of the State soldiers' and sailors' home, which occupies a beautiful site on a bluff overlooking both the lake and the city. Near by there is a monument erected to General Anthony Wayne, who died here on Dec. 15, 1796.

In 1753 the French built a stockade and blockhouse, called Ft. Presque Isle, on the site of Erie, and around it grew up a village. The village was abandoned, probably because of an epidemic of small-pox, in 1758, and the fort in 1759. It was occupied by the British in 1760; captured by the Indians on June 22, 1763, during the Conspiracy of Pontiac; regained by the British, under Col. Lionel Bradstreet, in 1764; and passed into the possession of the United States in 1785. The town was laid out in 1795, by General Andrew Ellicott, first surveyor-general of the United States, who had laid out Washington after the plan of L'Enfant. It became the county seat when Erie county was erected in 1803;

was incorporated as a borough in 1805, and as a city in 1851. Here, in six months, were built most of the vessels with which Commodore Oliver H. Perry won his naval victory over the British off Put-in-Bay on Sept. 10, 1813. In 1913 Perry's flagship, the "Niagara," was raised from the bottom of Misery Bay, on the shore of Presque Isle, where his fleet was sunk following the declaration of peace. It was rebuilt and re-equipped and anchored at the Public Dock, where it is maintained as a historic exhibit. The first iron battleship on the Great Lakes, the "Wolverine," now used as a naval training ship, was built at Erie in 1843, out of plates and equipment hauled by oxen from Pittsburgh, and this is still its home port. A replica of the blockhouse built by General Wayne, which protected the harbour in the early days and while Perry's fleet was under construction, has been erected on the original site. In 1850 the population of Erie was 5,858; in 1870, 19,646; in 1890, 40,634; in 1910, 66,525; and between 1910 and 1920 it increased 40·4%. Since 1910 the area of the city has increased nearly threefold.

ERIE CANAL: *see* New York State Barge Canal System.

ERIE, LAKE is the fourth largest of the Great Lakes of North America. Bordering on it are the States of Michigan, Ohio, Pennsylvania and New York, and the Province of Ontario, Canada. Its dimensions, surface elevations, etc., are as follows: length 240m.; width, 57m.; maximum depth, 210ft.; area in square miles of water surface, 4,990 in United States and 4,950 in Canada; drainage basin in square miles, 23,570 in the United States and 11,110 in Canada; standard low water, 570ft. above mean sea-level; lowest mean monthly stage (since 1860), 569·90ft., for year 1926, mean monthly stage, 570·98ft.; highest recorded stage (1838), 575·11ft.; mean surface, 67 years (1860–1926), above mean sea-level, 572·43ft.; mean surface below surface of Lake Huron, 8·54ft.; mean surface above mean surface of Lake Ontario, 326·33ft.; average season of navigation, from March 27 to Dec. 20; receives water from upper lakes via the Detroit river; discharges water into Lake Ontario via Niagara river.

Lake Erie is comparatively shallow and the storms which sweep over it quickly raise dangerous seas. As a result, the water level in the harbours, particularly those near each end of the lake, fluctuates markedly under the influence of the winds, varying with their direction, strength and persistence. Navigation from Lake Huron to Lake Erie passes through the St. Clair river, Lake St. Clair and the Detroit river. There are no locks in these rivers as the difference in elevation of the two lakes is small and currents in the connecting channel are moderate. The channels permit vessels of 20ft. to navigate them when the lakes are at standard datum. (*See* Great Lakes.) Navigation from Lake Erie to Lake Ontario passes through the Welland canal, constructed and operated by the Dominion of Canada. The present Welland canal affords a depth of 14ft. at normal lake levels. The new Welland ship canal, under construction by Canada, is 25m. in length, with seven locks, each having a lift of 46½ft., and one guard lock. The portions of this canal first excavated were given a depth of 25ft.; the later contracts provide for a depth of 27 feet. The depth over the sills of the locks is 30ft., to provide for subsequent enlargement of the canal reaches. The estimated cost of the new Welland ship canal, when completed, is $115,600,000. The New York State barge canal has one of its Great Lakes connections at Tonawanda, N.Y., on the Niagara river, but also maintains terminals at Buffalo. This canal is planned to accommodate boats with a loaded draught of 10½ft. and, because of overhead bridges, the superstructure of these boats must not extend more than 15ft. above the water-line.

The cheap transportation afforded by modern bulk freight carriers on the Great Lakes has made it possible to bring the iron ore of the Lake Superior region to Lake Erie ports to meet the coal from Pennsylvania and West Virginia. The important steel industry of the Lake Erie region, including the Pittsburgh district, results. The movement of iron ore to Lake Erie ports averages about 45,000,000 tons per year. Coal, to meet the industrial and domestic needs of the upper lakes region, is brought by rail from the mines of Pennsylvania and West Virginia, and furnishes part return cargoes. The total movement of coal on Lake Erie amounts to about 33,000,000 tons yearly. Limestone, used as a flux in ore furnaces, is another bulk commodity moving on Lake Erie in large quantities; some 5,000,000 tons are transported yearly. Practically all of this stone comes from the peninsula of Michigan on Lake Huron. The quality is excellent and an unlimited supply is available at the water's edge. Wheat and other grain from the prairie provinces of Canada and the great grain belt of the United States furnish enormous cargoes to eastern markets and for export. About 50% of the Canadian wheat is transhipped to boats suitable for passage through the present Welland and St. Lawrence canals to Montreal and Quebec; the remainder moves by rail from Canadian and United States ports on Lake Erie. Most of the United States wheat is transhipped via barge line and railroad from Buffalo, or milled at Buffalo or other Lake Erie ports. The maximum movements of wheat occur during the first and last months of the navigation season. With the opening of navigation, there is a rush of grain from the elevators at Duluth, Superior, Ft. William and Port Arthur, where it has been held in winter storage. There is then some movement from July on, but on or about Sept. 1 the tremendous flow of wheat from the Canadian provinces begins. The heaviest flow is usually during November. The traffic in short tons on Lake Erie for the period 1922–26 was as follows:

Year	Grain	Coal	Lime-stone	Iron Ore	Miscel-laneous	Total
1922	9,455,159	22,202,207	3,604,458	35,495,391	3,857,425	74,614,640
1923	7,282,784	36,245,782	5,288,734	48,833,267	4,077,989	101,728,556
1924	9,365,184	28,155,378	4,732,684	25,313,684	14,547,780	82,114,710
1925	8,852,966	30,209,286	4,816,734	42,950,324	5,590,526	92,419,836
1926	7,248,673	33,316,230	4,915,814	46,789,973	4,755,471	97,026,161

Originally a few harbours were formed by natural bays, but for the most part the harbours were found within the mouths of streams and were obstructed by bars at the entrances. As a result of Government, municipal and private work, numerous harbours have been improved to accommodate the present large lake vessels. The harbour works have consisted in dredging entrance and inner harbour channels and protecting them by piers and revetments, and in constructing breakwaters in the lake and deepening the enclosed areas in order to afford anchorage and mooring facilities and form commodious harbours outside of the

contracted harbours within streams. Nearly all the commerce of the lake centres at the mouth of the Detroit river, from which it radiates to the Welland canal, Niagara river and the various lake ports. The greater portion of traffic proceeds to the north of the island region in the western end of the lake, through Pelee passage between Point Pelee and Pelee island; this is the most important channel of the lake and is suitably marked by the Canadian Government. The most important ports of the United States on Lake Erie, with the water-borne tonnage of principal commodities in 1926, are shown in the accompanying table. Cleveland, Ashtabula and Conneaut are the most important iron ore ports. Toledo leads all the rest in its water shipments of soft coal and Buffalo is by far the largest grain port.

Lake Erie and its hinterland were the scenes of many conflicts of great importance in the early days of the settlement of the North American continent. Perry's famous victory over the British, at Put-in-bay near Sandusky, O., in Sept. 1813, was of far-reaching importance in securing the north-west for the United States at the Treaty of Ghent. Few naval battles had more momentous results. The name of Perry, his heroism and genius, will for ever inspire the American navy. (E. JA.)

ERIE RAILROAD COMPANY operates one of the leading trunk-line railroads connecting New York city with Chicago, Ill. The original company, the New York and Erie Railroad Company, incorporated by a special act of the legislature of the State of New York, April 24, 1832, met with financial reverses and was succeeded in 1861 by the Erie Railway Company, which was succeeded in 1878 by the New York, Lake Erie and Western Railroad Company, which latter was succeeded in turn by the present Erie Railroad Company, incorporated in New York in 1895 as the result of a reorganization of its predecessor company. The company operates 2,460 m. of railway, extending from Jersey City, N.J. (its main terminal) to Scranton, Pa., Rochester and Buffalo, N.Y., Cleveland and Cincinnati, O., and Chicago, Ill. The Erie Railroad Company owns the entire capital stock or holds under perpetual leases a large number of subsidiary lines which it operates, and owns a substantial majority of the capital stock of the New York, Susquehanna and Western and the New Jersey and New York railroads with a mileage of some 256 m. which are operated independently. It also owns the entire capital stock of four large coal companies with mines (both bituminous and anthracite) in eight counties in Pennsylvania, from which it receives a portion of its fuel supply and a large amount of coal traffic. Since the reorganization of 1895 almost $100,000,000 of revenue has been spent on the property, the road has been virtually rebuilt, grades have been reduced, heavier rails, bridges and stone ballast installed and double tracking completed until the Erie was in 1929 a first-class double-track, low-grade line between Jersey City, N.J., and Chicago, Ill.

For the year ending December 31, 1928 the total operating revenues were $124,724,273, of which merchandise contributed $77,203,615; coal $26,086,404; and passenger traffic $11,250,264. The surplus for the year was $8,282,847. The operating ratio for 1928 was 77·49 as compared with 81·86 in 1927. The company's investment was stated at $529,387,773. Capital stock consisted of $47,904,400, 4% non-cumulative first preferred, $16,000,000, 4% non-cumulative second preferred, and $151,116,700 common.

Beside a large anthracite traffic and a large general merchandise traffic, the Erie is second in number of commuters handled daily in and out of Greater New York. It also maintains a standard fast passenger service between New York, Buffalo, Cleveland, Chicago, and intermediate points. It is one of the so-called Van Sweringen group of railroads. (J. J. BE.)

ERIGENA, JOHANNES SCOTUS (*c.* 815–*c.* 877), mediaeval philosopher and theologian, was known to his contemporaries as Johannes Scotus (Scottus) or John the Scot, but in his versions of Dionysius the Areopagite he styles himself Johannes Ierugena. Eleventh century manuscripts have *Iohannes Ierugina, Erugena* and *Eriugena,* formed apparently on the analogy of Graiugena ("Greek-born"), and seemingly connected with Erin, the name for Ireland. Ierugena suggests the Greek ἱερός, ἱερὸς νῆσος being a common name for Ireland. (Prudentius, bishop of Troyes, definitely states that he was of Irish extraction.) The form *Erigena* is late and was not combined with *Johannes Scotus* until the 16th century.

Of Erigena's early life nothing is known. Bale quotes the story that he travelled in Greece, Italy and Gaul, and studied not only Greek, but also Arabic and Chaldaean, but Erigena's knowledge of Greek, though competent, is not such as to compel us to conclude that he actually visited Greece. It is certain, however, that Charles the Bald invited him to France shortly before 847 and made him head of the court school. The latter part of his life is involved in obscurity, and the story that he was invited to Oxford by Alfred the Great and that he afterwards taught at the abbey of Malmesbury has only the minimum of possibility.

Erigena marks the transition from the older Platonizing philosophy to the more rigid scholasticism, and is one of the most interesting of mediaeval writers. Utilizing especially Origen, Basil, Gregory of Nyssa, Augustine, Boethius and Maximas, he transforms them with the monistic colouring of the pseudo-Dionysius, and elaborates the first complete synthesis of the Middle Ages. Logically, but not intentionally, he is a pantheist, following in the wake of the pseudo-Dionysius whom he regards as the convert of St. Paul. Although he believes that authority and reason cannot be contradictory, he boldly asserts that reason must be the criterion. He does not start with the datum of theology as the completed body of truth requiring only interpretation; his fundamental thought is that of the universe, nature, or God, as the ultimate unity which works itself out into the rational system of the world. All things, including man, are parts of the system and are to be explained by reference to it; for explanation of a thing is determination of its place in the universal or all. Religion or revelation is one factor in the divine process, a stage of the ultimate rational life.

Erigena's first work was a treatise on the eucharist, no longer extant, and often wrongly identified with the *De corpore et sanguine Domini* of Ratramnus. But from the fragments on St. John's Gospel and from his contemporaries, it would appear that Erigena advanced the doctrine that the eucharist was merely symbolical or commemorative. His orthodoxy was not suspected at the time, and a few years later he was selected by Hincmar, archbishop of Rheims, to defend the doctrine of liberty of will against the extreme predestinarianism of the monk Gottschalk. The extant treatise, *De Divina Praedestinatione,* composed on this occasion (*c.* 851) was at once suspected. It was assailed by Drepanius Florus, canon of Lyons, and Prudentius of Troyes, and was condemned by two Councils—of Valence (855) and Langres (859). It starts with the bold affirmation that philosophy, and religion are fundamentally one and the same, and goes on to assert that because God is independent of time, predestination can only be asserted of Him inasmuch as by His free-will he allows the activities of creatures. It cannot involve any notion of necessity either in God or in man. In any case, predestination could only be to grace and happiness, for evil is merely negation of good; and moreover, if God knew evil, He would cause it because His knowledge and His will are identical.

Erigena's next work (*c.* 858) was a Latin translation of the works of the pseudo-Dionysius (*see* DIONYSIUS AREOPAGITICUS) undertaken at the request of Charles the Bald from the manuscripts of the abbey of St. Denys, Paris, which Dionysius was said to have founded. It has been preserved and fragments of Erigena's commentary on the original have been discovered. His great work, *De divisione naturae,* written *c.* 865–870, was condemned by a council at Sens, by Honorius III. (1225), and by Gregory XIII. in 1585. In it he maintains that *Natura* is the name for the totality of all things, containing in itself being and non-being, and covering (1) that which creates and is not created; (2) that which is created and creates; (3) that which is created and does not create; (4) that which neither is created nor creates. The first is God as the source of all things, the last is God as the final end of all things. The second and third together compose the created universe, which is the manifestation of God, God *in processu, Theophania.* The second covers the primordial ideas, archetypes, immutable relations, divine acts of will,

according to which individual things are formed. The third is the world of individuals, the effects of the primordial causes, without which the causes have no true being. Neither the ideas nor individual creatures have any self-independent existence; they are only in God; and each thing is a manifestation of the divine. God alone, the uncreated creator of all, has true being. He is the true universal, all-containing, infinite and incomprehensible. True theology must be negative, for God is above truth, wisdom, goodness, etc. (In this sense, He is nothing, and hence the nothing out of which things are created is identifiable with the divine nature.) Nevertheless the world, as the revelation of God, tells us something of the divine essence. We recognize His being in the being of things, His wisdom in their order, His life in their constant motion. Thus God is for us a Trinity—the Father as substance of being, the Son as wisdom, the Spirit as life. In man, the noblest of creatures, this Trinity is reflected in *intellectus, ratio* and *sensus.*

From the infinite essence of God emanates the realm of ideas in the Platonic sense. These ideas, which constitute a divine self-determination, are eternally created and are maintained in unity by the divine Logos. The highest idea is that of *goodness;* things *are,* only if they are good; being without well-being is naught. *Essence* participates in goodness—that which is good has being, and is therefore to be regarded as a species of good. *Life,* again, is a species of essence, *wisdom* a species of life, and so on, always descending from genus to species in logical fashion.

Under the moving influence of the spirit, the ideas manifest themselves in created things. Manifestation is part of the essence of the causes; as the causes are eternal, timeless, so creation is eternal, timeless. The Mosaic account, then, is allegorical. Paradise and the Fall have no spatial or temporal being. Only after the introduction of sin did man lose his spiritual body and acquire the animal nature with its distinction of sex.

The most remarkable and at the same time the most obscure portion of the work is that in which the final return to God is handled. Naturally, sin is a preliminary to this redemption, but Erigena has great difficulty in accounting for it. If God is true being, then sin can have no substantive existence; it cannot be said that God knows of sin, for to God, knowing and being are one. In the universe of things, *as* a universe, there can be no sin; there must be perfect harmony. Sin, in fact, results from the will of the individual who falsely represents something as good which is not so. This misdirected will is punished by finding that the desired objects are vain, and hell is the inner state of the sinful will. The result of punishment is the final purification and redemption of all, even animals and devils. The ultimate goal is *deificatio* or resumption into the Divine Being, when the individual soul is raised to a full knowledge of God, and where knowing and being are one. Erigena's doctrines seem to have influenced such divers thinkers as Heric and Remigius of Auxerre, Gerbert, Berengerius, Gilbert de la Porée, Abelard, Alan of Lille, the Chartres men, Amalric of Bene and Nicholas of Cusa. Hugh of St. Victor utilized his translation of the pseudo-Dionysius.

BIBLIOGRAPHY.—There is a complete edition of Erigena's works by H. J. Floss in Migne's *Patrol* Lat. (vol. cxxii.). The *De divina praedestinatione* was also published at Paris (1650); the *Expositiones* on Dionysius' *Hierarchiae caelestes* at Rome (1871); the *De divisione naturae* at Oxford (1681) and at Münster (1838); and his poems have been edited by L. Traube in *Monum. Germ. historica. Poetae Lat. aevi Carolini,* iii. (1896). A commentary on the *Opuscula sacra* of Boetius has been edited by E. K. Rand (1906), and the commentary on Martianus Capella by Hauréau in *Notices et extraits des MSS.* (1862). *See* St. Rene Taillandier, *Scot Érigène et la philosophie scholastique* (1843); T. Christlieb, *Leben u. Lehre des Johannes Scotus Erigena* (Gotha, 1860); J. N. Huber, *Scotus Erigena* (Munich, 1861); R. L. Poole, *Medieval Thought* (2nd ed., 1920); A. Methode* (Freiburg i/B, 1911) and Überweg, *Grund. der Gesch. der Phib.* Pt. II. (1915) with full bibliography.

ERIGONE, in Greek mythology, daughter of Icarius, the hero of the Attic deme Icaria. Her father, who had been taught by Dionysus to make wine, gave some to some shepherds, who became intoxicated. Their companions thinking they had been poisoned, killed Icarius and buried him under a tree on Mount Hymettus (or threw his body into a well). Erigone, guided by her faithful dog Maera, found his grave and hanged herself on the tree. Dionysus sent a plague on the land, and all the maidens of Athens, in a fit of madness, hanged themselves like Erigone. Icarius, Erigone, and Maera were set among the stars as Boötes (or Arcturus), Virgo, and Procyon. The festival called Aeora (the "Swing") was subsequently instituted to propitiate Icarius and Erigone. Various small images (Lat. *oscilla*) were suspended on trees and swung backwards and forwards and offerings of fruit were made (Hyginus, *Fab. 130, Poët. astron.* ii. 4; Appolodoros iii. 191–2). The story was probably intended to explain the origin of these *oscilla.*

ERIN (ĕr-ụn, Eng. ēr′ĭn), an ancient name for Ireland. The oldest form of the word is Ériu (Mid. Irish *Hériu,* dative *Hérinn*), of which Érinn is the dative case. Ériu was itself almost certainly a contraction from a still more primitive form *Iveriū* for an older **Iveriō* (or **Piveriō; cf.* Πιέριος, Πιερία) for when the name of the island was written in ancient Greek it appeared as Ἰουερνία (Ivernia), and in Latin as *Iberio, Hiberio* or *Hibernia,* the first syllable of the word Ériu being thus represented in the classical languages by two distinct vowel sounds separated by *b* or *v.* Of the Latin variants, *Iberio* is the form found in the most ancient Irish mss., such as the *Confession* of St. Patrick, and the same saint's *Epistle to Coroticus.* Further evidence to the same effect is found in the fact that the Welsh name for Ireland was Iwerddon, whence the Breton *Yuerdon,* a learned borrowing from Welsh. In later Gaelic literature the primitive form Ériu became the dissyllable Éire; hence the Norsemen called the island the land of Éire, *i.e.,* Ireland, the latter word being originally pronounced in three syllables. (*See* IRELAND.) Nothing is known as to the meaning of the word in any of its forms, and Whitley Stokes's suggestion that it may have been connected with the Sanskrit *avara,* meaning "western," is admittedly no more than conjecture. There was, indeed, a native Irish legend, worthless from the standpoint of etymology, to account for the origin of the name. According to this myth there were three kings of the Dedannans reigning in Ireland at the coming of the Milesians, named MacColl, MacKecht and MacGrena. The wife of the first was Eire, and from her the name of the country was derived. Curiously, Ireland in ancient Erse poetry was called "Fodla" or "Banbha," and these were the wives of the other two kings in the legend.

ERINNA, Greek poet, friend of Sappho, flourished about 600 (according to Eusebius, 350 B.C.). Although she died at the age of 19, her poems were among the most famous of her time. Of her best known poem Ἠλακάτη (the *Distaff*), written in a mixture of Aeolic and Doric, which contained 300 hexameter lines, only four lines are now extant. Three epigrams in the Palatine anthology, also ascribed to her, probably belong to a later date.

The fragments have been edited (with those of Alcaeus) by J. Pellegrino (1894).

ERINYES (ĕ-rēn-ü-es), less correctly ERINNYES, in Greek mythology, the name given to the avenging deities, probably personified curses, but possibly in their origin ghosts of the murdered (Lat. *Furiae*). According to Hesiod (*Theog.,* 185) they were the daughters of Earth, and sprang from the blood of the mutilated Uranus; in Aeschylus (*Eum.,* 321) they are the daughters of Night, in Sophocles (*O.C.,* 40), of Darkness and Earth. Sometimes one Erinys is mentioned, sometimes several. Euripides first spoke of them as three in number, to whom later Alexandrian writers gave the names Alecto (unceasing in anger), Tisiphone (avenger of murder), Megaera (jealous).

Their home is the world below, whence they ascend to earth to pursue the wicked. They punish all offences against the laws of human society, such as perjury, violation of the rites of hospitality, and, above all, the murder of relations. Though just, they are merciless and take no account of mitigating circumstances. Being deities of the underworld, they are often identified with spirits of the fertility of the earth, as the Semnai or Eumenides (*q.v.*) at Athens. (*See* DEMETER.) In Aeschylus, the Erinyes are represented as awesome, Gorgon-like women wearing

long black robes, with snaky locks, bloodshot eyes, and claw-like nails. Later, they are winged maidens of serious aspect, in the garb of huntresses, with snakes or torches in their hair, carrying scourges, torches or sickles.

See J. E. Harrison, *Prolegomena to the Study of Greek Religion* (1903); E. Rohde, *Psyche;* A. Rapp, in Roscher's *Lexikon;* and J. A. Hild in Daremberg-Saglio, s.v. FURIAE.

ERIS, in Greek mythology, a sister of the war-god Ares (Homer, *Iliad,* iv. 440), and in the Hesiodic theogony (225) a daughter of Night. In the later legends of the Trojan war, Eris, not having been invited to the marriage festival of Peleus and Thetis, flings a golden apple, the "apple of discord," among the guests, to be given to the most beautiful. The claims of the three deities, Hera, Aphrodite and Athena, are decided by Paris in favour of Aphrodite, who as a reward assists him to gain possession of Helen (Hyginus, *Fab.,* 92; Lucian, *Charidemus,* 17). Hesiod also mentions (*Works and Days,* 24) a beneficent Eris, the personification of honourable rivalry. In Virgil (*Aeneid,* viii. 702) and other Roman poets, Eris is represented by Discordia.

ERISTIC, the art of disputation, especially that form of it which aims at personal triumph rather than at the discovery of truth (Greek ἔρις, strife). The Eristics were a group of Sophists led apparently by Euclid of Megara (hence their other name, the Megarians), who were specially addicted to dialectical puzzles (mostly borrowed or adapted from the Eleatics) and other debating tricks. It was through them and their like that the name of Sophist, otherwise an honourable name, eventually fell into disrepute. *See* MEGARIAN SCHOOL, and SOPHISTS.

ERITH, an urban district in the Dartford parliamentary division of Kent, England, 15 m. E. by S. of London, on the Southern railway. Pop. (1921) 31,558. It lies on the south bank of the Thames and extends up the hills above the shore, many villas having been erected on the higher ground. The church of St. John the Baptist (restored) goes back to Norman times and contains many interesting early monuments and brasses. Erith has large engineering and gun factories, and in the neighbourhood are gunpowder, oil, glue and manure works, as well as large brick fields from which sand and loam are also exported. The southern outfall works of the London main drainage system are at Crossness in the neighbouring lowland called Plumstead marshes. To the west of Erith lie Abbey Wood and Belvedere (the ancient district of Lessness or Lessnes Heath), with the county technical college and secondary school, and the home (1856) for aged merchant seamen in Belvedere park. The tract of Bostall Heath (155 ac.) below Plumstead is maintained by the London county council as an open space. Erith is the headquarters of several yacht clubs. Erith, the name of which is derived from Anglo-Saxon meaning the old, or shore, *hythe* or haven, is mentioned in a Latin charter of the seventh century in connection with a gift of land made by the bishop of the East Saxons. It was anciently a borough, and was granted a market and fairs in 1313. Down to the close of the 17th century it was of some importance as a naval station. Erith council maintains tramway and electricity undertakings and recreation grounds and parks, including Franks park (40 ac.). The district lies within the metropolitan police district of Greater London.

ERITREA (*ā-rē-trā'ą*), an Italian colony on the African coast of the Red sea. Area, 45,734 sq.m. Pop. (1925) 410,000, including 4,251 Europeans, of whom 3,901 were Italians. It extends from Ras Kasar, a cape 110 m. S. of Suakin, in 18° 2′ N., as far as Ras Dumeira (12° 42′ N.), in the Strait of Bab-el-Mandeb, a coastline of about 650 miles. The colony is bounded inland by the Anglo-Egyptian Sudan, Abyssinia and French Somaliland. The colony corresponds neither to ethnic nor geographical divisions, and its frontiers, like so many other frontiers in Africa, are almost entirely arbitrary lines. The Dahlak archipelago and other groups of islands along the coast belong to Eritrea.

Physical Features.—The coast-line is of coral formation and is in the neighbourhood of Massawa, thickly studded with small islands. The chief indentations are Annesley bay, immediately south of Massawa, and Assab bay in the south. The colony consists of two widely-differing regions. The northern division, which is the main part of the colony is mostly part of the Abyssinian plateau, reached from the coast by a steep escarpment. The southern division is part of the Afar or Danakil country. These two regions are connected by a narrow strip of land behind Annesley bay, where the Abyssinian hills approach close to the sea. Southward from this bay the coast-line trends south-east so that at Tajura bay the distance between the Abyssinian hills and the sea is over 200 miles. The Afar country is part of the East African rift-valley, and in the southern parts of the valley its surface is diversified by ranges of hills, frequently volcanic, and by lakes. Here the frontier is drawn 60 kilometres (37·28 m.) from the coast line, so that most of the Afar country belongs to Abyssinia. The volcano of Alid (2,985 ft.) is in Italian territory. Around it is a vast lava field.

At Annesley bay the narrow coast plain is succeeded by foothills separated by small valleys through which flow innumerable streams. From these hills the ascent to the plateau which constitutes northern Eritrea is very steep. This tableland, which has a general elevation of about 6,500 ft. is fairly fertile despite a desert region—Sheb—to the south-east of Keren. It is characterized by rich, well-watered valleys, verdant plains and flat-topped hills with steep sides, running in ranges or isolated. The highest hills in Eritrean territory rise to about 10,000 feet. The plateau is known by various names, the region directly west of Massawa being called Hamasen. To the west and north the plateau sinks in terraces to the plains of the Sudan, and eastward falls more abruptly to the Red sea, the coast plain, known as the Samhar, consisting of sandy country covered with mimosa and, along the khors, with a somewhat richer vegetation.

The colony contains no navigable streams. For a short distance the Setit (known in its upper course as the Takazze), a tributary of the Atbara forms the frontier, as does also in its upper course the Gash or Mareb (*see* ABYSSINIA). The Mareb, often dry in summer, in the floods is a large and impassable river. The Baraka (otherwise Barka) and Anseba rise in the Hamasen plateau, near Asmara, within a short distance of each other. The Baraka flows west and then north; the Anseba, which has a more easterly course, also flows northward and joins the Baraka a little north of 17° N. A few miles below the confluence the Baraka enters Sudan territory, and after heavy rain discharges some of its water into the Red sea north of Tokar. The watershed separating the Nile basin from the Red sea streams lies between the Mareb and the Khor Baraka.

In the coast zone the heat and humidity are excessive during most of the year, June, September and October being the hottest months. Rains occur between November and April, during which time the temperature is lower. At Massawa the mean temperature is 86° F, but in summer the thermometer often rises to 120° F in the shade, and the mean for July is 94° F. Rainfall at Massawa is not more than 8 in. a year; at Arsab not more than 2 inches. In the region comprising the slopes of the plateau and up to about 6,000 ft. heat and humidity still prevail, but the temperature is lower and the rainfall rises to 14 inches. On the high plateau the climate is generally moderately cool, with a yearly mean of 67° F. Slight rain falls in the spring and abundant monsoon rains from June to September. On the plateau the climate is suitable for European settlement. Above 8,500 feet the climate becomes sub-alpine in character.

In the low country the flora differs little from that of tropical Africa generally, whilst on the plateau the vegetation is characteristic of the temperate zone. The olive tree grows on the high plateau and covers the flanks of the hills to within 3,000 ft. of sea level. The sycamore fig-tree grows to enormous proportions in parts of the plateau. Lower down durra, maize and bultuc grow in profusion. In the northern part of the colony, especially along the Khor Baraka, the dom palm flourishes. The fauna includes, in the low country, the lion, panther, elephant, camel and antelope of numerous species. On the plateau the fauna is that of Abyssinia (*q.v.*).

Inhabitants.—The inhabitants of the plains and foothills are for the most part semi-nomad shepherds, living on durra and milk. In the north these people are largely of Arab or Hamitic stock,

such as the Beni-Amer, but include various negro tribes. Afar and Somali form the population of the southern regions. The inhabitants of the plateau are Abyssinians. Some 115,000 of the Abyssinians are Copts, the rest are Mohammedans; and Islam is the faith of most of the other tribes. The languages spoken by the Abyssinians are Tigrai and Tigre. A warlike race, they have settled down under Italian rule. They furnish the defence force of the colony (5,000 strong in 1927). Among the native industries are mat-weaving, cotton-weaving, silver-working and rudimentary iron and leather working. (*See* AFARS; SOMALILAND; ABYSSINIA.)

Towns and Communications.—The chief and only good port is Massawa (*q.v.*). Assab is a roadstead in the Danakil country. Zula (*q.v.*), on the shores of Annesley bay, is identified with the ancient Adulis. On the plateau are Asmara (*q.v.*), the capital, Keren (Cheren), Agordat, Adi Kaleh, Adi Urgi and Barentu, all headquarters of administrative divisions. A railway from Massawa climbs to and crosses the highlands. The section to Asmara, 75 m., completed in 1912, rises to 7,765 ft., the altitude of Asmara. Thence the railway was continued via Keren to Agordat (reached in 1926), and Tessenei, the centre of the cotton-growing area. From Agordat a high road goes west to Kassala in the Sudan. From Keren another main road runs south to Adowa, in Tigre (Abyssinia). In the south, from Assab a road runs west to tap the trade of central Abyssinia. Besides these principal routes there are many secondary roads and camel and mule paths. Every valley leading to the plateau has its ancient way; one of the most frequented is from Annesley bay up the valley of the Hadas river. There is a well-developed telegraphic system, Massawa being in communication by land lines with Adis Ababa and by cable and wireless with the outer world. Massawa is also a regular port of call for several steamship lines.

Agriculture and Trade.—Agriculture is practically confined to the highlands. The Abyssinians are good agriculturists and cultivate cereals (wheat, barley, durra), beans and peas, coffee and other food crops. Linseed and other oil seeds, flax fibres, dates and tobacco are other products. The chief wealth of the people consists, however, in their sheep, cattle, camels, donkeys and other live stock. State-aided attempts to settle Italian agriculturists on the soil began in 1890; the first experiments were a failure. About 1,900 private individuals succeeded in making profitable farms near Asmara, and their example was copied. But as the Abyssinians held nearly all the best land the scope for Italians was limited. The coast zone produces salt, and there are valuable pearl and mother-of-pearl fisheries off the Dahlak archipelago.

For many years Italian capitalists showed a disinclination to invest money in the colony, and enterprise by other Europeans was discouraged. The chief industry, which owes its inception to the Italians, is cotton growing in the valleys of the Gash and Baraka rivers. After many years of experimenting, suitable varieties of cotton were found, ginneries were built at Asmara and Massawa, and a beginning was made with irrigation works in the Gash area in 1915. The Gash ends in an inland delta in the Kassala province of the Sudan, and an agreement, made in 1925 with the Sudan Government, regulated the use of its waters by the two countries. In 1926–27 some 6,000 ac. were under cotton and the production of lint 478,000 lb. This was nearly double the output in 1922.

The external trade developed at first slowly; in 1901 it was valued at about £450,000; in 1911 at about £1,175,000, and in 1913 at over £1,500,000. After the World War development was more rapid and the external trade in 1926 was valued at £3,730,000 (imports £2,370,000; exports £1,360,000). These figures include the transit trade with Abyssinia and the Sudan. The excess of imports over exports was a constant and marked feature of external trade. Besides cotton goods and food stuffs the imports included machinery, railway material and all the goods required in the development of the colony. The most valuable exports were skins and hides, coffee, linseed and vegetable ivory (the nut of the dum palm) in which there was a marked growth. Other exports of value were salt, potash, a little gold (from mines near Asmara), mother-of-pearl and pearls. Trade is mainly with Italy.

Administration and Revenue.—A civil administration was established in 1898. The governor is responsible to the minister of the colonies and is assisted by a body consisting of the heads of departments. There is no legislative council and no direct representation of the people, though, in purely local matters, village headmen, councils of elders and tribal chiefs aid the Italian officials. The colony is divided into commissariats, each with their local organizations. In the administration special attention is devoted to health, education and public works. There is an independent judiciary with the right of appeal for non-natives to the Rome court of cassation. The civil laws for the natives are those sanctioned by local usage and they are administered by native tribunals, with the right of appeal to the colonial court of appeal.

Revenue is derived from customs duties, direct taxation and other sources. For 35 years Eritrea was a charge on the Italian treasury, largely because of the expenditure on the military establishment. From 1920, however (when the State contribution was 6,650,000 lire, in a total budget of 24,121,000 lire), the cost of civil administration was almost met by local revenue. The budget of 1927–28 was balanced at 42,550,000 lire, the civil expenditure being returned at 26,330,000 lire and military expenditure at 16,125,000 lire. No subsidy was required from Italy.

(F. R. C.)

History.—Traces of the ancient Eritrean civilization are scarce. During the prosperous periods of ancient Egypt, Egyptian squadrons asserted their rule over the west Red Sea coast, and under the Ptolemies the port of Golden Berenice (Adulis?) was an Egyptian fortress, afterwards abandoned. During the early years of the Roman empire, Eritrea formed part of an important independent state—that of the Axumites (Assamites). At the end of the reign of Nero, and perhaps even earlier, the king of the Axumites ruled over the Red Sea coast from Suakin to the Strait of Bab-el-Mandeb, and traded constantly with Egypt. This potentate called himself "king of kings," commanded an army and a fleet, coined money, adopted Greek as the official language, and lived on good terms with the Roman empire. The Axumites belonged originally to the Hamitic race, but the immigration of the Himyaritic tribes of southern Arabia speedily imposed a new language and civilization. Therefore the ancient Abyssinian language, Geez, and its living dialects, Amharic and Tigrina, are Semitic, although modified by the influence of the old Hamitic Agau or Agao. Adulis (Adovlis), slightly to the north of Zula (*q.v.*), was the chief Axumite port. From Adulis started the main road, which led across the high plateau to the capital Axomis (Axum). Along the road are still to be seen vestiges of cities and inscribed monuments, such as the Himyaritic inscriptions on the high plateau of Kohait, the six obelisks with a Saban inscription at Toconda, and an obelisk with an inscription at Amba Sait. After the rise of the Ethiopian empire the history of Eritrea is bound up with that of Ethiopia (*see* ABYSSINIA), but the documents of the Portuguese expedition of the 16th century and other Ethiopian records show that all the country north of the Mareb enjoyed relative autonomy under a vassal of the Ethiopian emperor.

Michael, counsellor of Solomon, who was king of the country north of the Mareb, usurped the throne of Solomon during the reign of the Emperor Atzié Jasu II. (1729–53), and, after proclaiming himself ras of Tigré and "protector of the empire," ceded the North Mareb country to an enemy of the rightful dynasty. Hence a long struggle between the dispossessed family and the occupants of the North Mareb throne. The coast regions had meantime passed from the control of the Abyssinians. In the 16th century the Turks made themselves masters of Zula, Massawa, etc., and these places were never recovered by the Abyssinians. In 1865 Massawa and the neighbouring coast was acquired by Egypt, the khedive Ismail entertaining projects for connecting the port by railway with the Nile. The Egyptians took advantage of the civil war in Abyssinia to seize Keren and the Bogos country in 1872, an action against which the negus Johannes (King John), newly come to the throne, did not then protest. In 1875 and 1876 the Egyptians, who sought to increase their conquests, were defeated by the Abyssinians at Gundet and Gura. Walad Michael, the hereditary ruler of Bogos, fought as ally of King John at Gundet and of the Egyptians at Gura. For two years Walad Michael continued to harass the border, but in Dec.

1878 he submitted to King John, by whose orders he was (Sept. 1879) imprisoned upon an amba, or flat-topped mountain, whence he only succeeded in escaping in 1890. In 1879 his territory was given by King John to Ras Alula, who retained it until, in August 1889, the Italians occupied Asmara.

An Egyptian garrison remained at Keren in the Bogos country until 1884, when in consequence of the revolt of the Mahdi it was withdrawn, Bogos being occupied by Abyssinia on Sept. 12 of that year. On Feb. 5, 1885, an Italian force, with the approval of Great Britain, occupied Massawa, the Egyptian garrison returning to Egypt. This occupation led to wars with Abyssinia and to the establishment of the colony in its present limits. For Italo-Abyssinian relations *see* ITALY and ABYSSINIA.

The purchase of Assab and the neighbouring region for £1,880, from the Sultan Berehan of Raheita for use as a coaling station by the Italian Rubattino Steamship Company, in March 1870, formed the nucleus of Italy's colonial possessions. This purchase was protested against by Egypt, Turkey and Great Britain, but eventually, the British opposition being overcome and that of Egypt and Turkey disregarded, Assab, by a decree of July 5, 1882, was declared an Italian colony. Between 1883 and 1888 various treaties were concluded with the sultan of Aussa ceding the Danakil coast to Italy and recognizing an Italian protectorate over the whole of his country—through which passes the trade route from Assab bay to Shoa.

On Jan. 1, 1890, the various Italian possessions on the coast of the Red sea were united by royal decree into one province under the title of the Colony of Eritrea—so named after the Erythraeum Mare of the Romans. At first the government of the colony was purely military, but after the defeat of the Italians by the Abyssinians at Adowa (1896), the administration was placed upon a civil basis. The frontiers were further defined by a French-Italian convention (Jan. 24, 1900) fixing the frontier between French Somaliland and the Italian possessions at Raheita, and also by various agreements with Great Britain and Abyssinia. A tripartite agreement between Italy, Abyssinia and Great Britain, dated May 15, 1902, placed the territory of the Kanama tribe, on the north bank of the Setit, within Eritrea. A convention of May 16, 1908, settled the Abyssinian-Eritrean frontier in the Afar country, the boundary being fixed at 60 km. from the coast. The task of reconstructing the administration on a civil basis and of developing the commerce of the colony was entrusted to Signor F. Martini, who was governor for nine years (1898–1906). Under civil rule the colony made steady though somewhat slow progress and has become economically prosperous. The native forces, known as *Ascari,* rendered useful services in the wars against Abyssinian and other tribes, and in the Libyan War. On Aug. 2, 1928, a private agreement arranged for the cession to Abyssinia of a free zone at the port of Assah, and the construction of a road thence to Addis Ababa.

ERIVAN or **IRWAN,** (1) the capital town of Armenian S.S.R. situated in 40° 16′ N., 44° 35′ E., 234 m. by rail south-west of Tiflis, on the Zanga river, from which a great number of irrigation canals are drawn. Altitude, 3,170 feet. Pop. (1926) 62,180. After the creation of the Armenian Republic, an Armenian University was founded at Erivan, and also an Armenian National Museum and an Institute of Music. The population has increased markedly and there are several industrial undertakings including the making of machinery, wine and brandy distilling, rice preparation, brick, leather and furniture factories. In 1928 a factory for extracting glycerine from the oil of cotton was successfully established. A new hydro-electric station, designed by the Armenian architect, Tamarian, was opened in 1926. The old Persian portion of the town consists mainly of narrow crooked lanes enclosed by mud walls, which effectually conceal the houses, and the modern Russian portion is laid out in long ill-paved streets. On a steep rock, rising about 600 ft. above the river, stand the ruins of the 16th-century Turkish fortress, containing part of the palace of the former Persian governors, a handsome but greatly dilapidated mosque, a modern Greek church and a cannon foundry. One chamber, called the Hall of the Sardar, bears witness to former splendour in its decorations. The finest building in the city is the mosque of Hussein ali Khan, familiarly known as the Blue Mosque from the colour of the enamelled tiles with which it is richly encased. At the mosque of Zal Khan a passion play is performed yearly illustrative of the assassination of Hussein, the son of Ali. Erivan is an Armenian episcopal see, and has a theological seminary. Armenians, Persians and Tatars are the principal elements in the population, besides some Russians and Greeks. The town fell into the power of the Turks in 1582, and was taken by the Persians under Shah Abbas in 1604, besieged by the Turks for four months in 1615, and reconquered by the Persians under Nadir Shah in the 18th century. In 1780 it was successfully defended against Heraclius, prince of Georgia; and in 1804 it resisted the Russians. At length in 1827 Paskevich took the fortress by storm, and in the following year the town and government were ceded to Russia by the peace of Turkman-chai. A Tatar poem in celebration of the event has been preserved by the Austrian poet, Bodenstedt, in his *Tausend und ein Tage im Orient* (1850). (2) an administrative district of the Armenian S.S.R. with the town of Erivan as its centre. It has an area of 3,975 sq.km. and a population (1926) of 175,816. The district is noted for its vineyards and for its apples, apricots and melons.

ERLANGEN, a town of Germany, in the republic of Bavaria, on a fertile plain, at the confluence of the Schwabach and the Regnitz, 11 m. N.W. of Nuremberg, on the railway from Nuremberg to Bamberg. Pop. (1925) 29,597. In 1017 Erlangen was transferred from the bishopric of Würzburg to that of Bamberg; in 1361 it was sold to the king of Bohemia. It became a town in 1398 and passed into the hands of the Hohenzollerns, burgraves of Nuremberg, in 1416. It owes the foundation of its prosperity chiefly to the French Protestant refugees who settled here on the revocation of the edict of Nantes and introduced various manufactures. In 1810 it came into the possession of Bavaria. Erlangen was for many years the residence of the philosophers Johann Gottlieb Fichte and Friedrich Wilhelm von Schnelling. It is divided into an old and a new town. Upon the market place stand the town hall and the former palace of the margraves of Bayreuth, now the main building of the university. The latter was founded by the margrave Frederick (d. 1763), who, in 1742, established a university at Bayreuth, but in 1743 removed it to Erlangen. The chief industries of Erlangen are the manufacture of electrical apparatus, horn ware, leather, paper, brushes and gloves. The beer of Erlangen is famous throughout Germany and large quantities are brewed and exported.

ERLANGER, CAMILLE (1863–1919), French composer, was born in May, 1863, and studied at the Paris Conservatoire. He made his reputation in 1896 with *Saint-Julien l'Hospitalier,* a dramatic legend, the libretto of which was founded on the story of Flaubert. His other more important works were *Le Juif Polonais* (1900), *Aphrodité* (1906) and *La Sorcière* (1912).

ERLE, SIR WILLIAM (1793–1880), English lawyer and judge, was born at Fifehead-Magdalen, Dorset, on Oct. 1, 1793,

and was educated at Winchester and at New college, Oxford. Having been called to the bar at the Middle Temple in 1819 he went the western circuit, became counsel to the Bank of England, sat in parliament from 1837 to 1841 for the city of Oxford, and was made a judge of the common pleas in 1845. He was made Chief Justice of the Common Pleas in 1859, retired in 1866 and died at Bramshott, Hampshire, on Jan. 28, 1880.

See E. Manson, *Builders of our Law* (1904).

ERLKÖNIG or **ERL-KING,** a mythical character in modern German literature, does not exist in ancient German mythology. The name is linguistically merely the perpetuation of a blunder in Herder's *Stimmen der Völker* (1778), where it is used in the translation of the Danish song of the *Elf-King's Daughter* as equivalent to the Danish *ellerkonge, ellekonge,* or *elverkonge,* king of the elves; the true German word would have been *Elbkönig* or *Elbenkönig*, afterwards modified to *Elfenkönig* by Wieland in his *Oberon* (1780). Herder was probably misled by the Danish word *elle* signifying both elf and alder tree (Ger. *Erle*). His mistake has been perpetuated by both English and French translators, who explain the myth in the tree-worship of early times, or in the vapoury emanations round alder trees at night. The legend was adopted by Goethe as the subject of one of his finest ballads, and has been treated as a musical theme by Reichardt and Schubert.

ERMANARIC (*fl.* 350–376), king of the East Goths, belonged to the Amali family, and was the son of Achiulf. His name occurs as Ermanaricus (Jordanes), Aírmanareiks (Gothic), *Eormenric* (A. Sax.), Jörmunrek (Norse), Ermenrîch (M.H. German). His vast kingdom eventually extended from the Danube to the Baltic and from the Don to the Theiss, but in his later days the west Goths threw off his yoke, and, on the invasion of the Huns, rather than witness the downfall of his kingdom, Ermanaric is said by Ammianus Marcellinus to have committed suicide. His fate early became the centre of popular tradition, which found its way into the narrative of Jordanes or Jornandes (*de rebus geticis,* chap. 24), who compared him to Alexander the Great and certainly exaggerated the extent of his kingdom. In German legend Ermanaric became the typical cruel tyrant, and references to his crimes abound in German epic and in Anglo-Saxon poetry. He is made to replace Odoacer as the enemy of Dietrich of Bern, his nephew, and his history is related in the Norse *Vilkina* or *Thidrekssagà,* which chiefly embodies German tradition. The tale is told with variations by Saxo Grammaticus (*Historia Danica,* ed. Müller, p. 408, etc.), and in the Icelandic poems, the *Lay of Hamtheow, Gudrun's Chain of Woe,* and in the prose *Edda.*

BIBLIOGRAPHY.—W. Grimm, in *Die deutsche Heldensage* (2nd ed., 1867), quotes the account given by Jordanes, references in Beowulf, in the *Wanderer's Song, Exeter Book* in *Parcival,* in *Dietrichs Flucht,* the account given in the *Quedlinburg Chronicle,* by Ekkehard in the *Chronicon Urspergense,* by Saxo Grammaticus, etc. *See* also Vigfússon and Powell, *Corpus poëticum boreale,* vol. i. (Oxford, 1883), and H. Symons, "Die deutsche Heldensage" in Paul's *Grundriss d. german. Phil.* vol. iii. (Strassburg, 1900). R. C. Boer, "Die Sagen von Ermanarich" etc., in *Germanistische Handbibliothek* (vol. x. Halle, 1910).

ERMELAND or **ERMLAND** (*Varmia*), a district in East Prussia, extending from the Frisches Haff inland towards the Polish frontier. It is a well-wooded sandy tract of country, has an area of about 1,650sq.m., a population of 240,000, and is divided into the districts of Braunsberg, Heilsberg, Rössel and Allenstein.

Ermeland was originally one of the 11 districts of old Prussia and was occupied by the Teutonic Knights, being made in 1250 one of the four bishoprics of the country under their sway. The bishop of Ermeland shortly afterwards declared himself independent of the order, and became a prince of the empire. In 1466 Ermeland, together with West Prussia, was by the peace of Thorn attached to the crown of Poland, and the bishop had a seat in the Polish senate. In 1772 it was again incorporated with Prussia.

See Hipler, *Literaturgeschichte des Bisthums Ermeland* (Braunsberg, 1873); the *Monumenta historiae Warmiensis* (Mainz, 1860–64, and Braunsberg, 1866–72, 4 vols.); and Buchholz, *Abriss einer Geschichte des Ermlands* (Braunsberg, 1903).

ERMELO, a magisterial district of the Transvaal, bordering on Swaziland, and including the sources of the Vaal, Olifants, Komati and Usuto rivers. The general elevation of the region is over 5,000 feet. The principal occupations are pastoralism and agriculture. A considerable amount of maize is grown. Coal and gold are also found. Ermelo is the chief town of the district; 26° 31′ S., 29° 59′ E.; altitude, 5,689 feet. Population (1921), 2,742 Europeans, 1,804 coloured. The town is 171 m. by rail from Johannesburg. Adjoining the town lands is a Government experimental farm, devoted chiefly to pastoral problems, though about 1,000 ac. are under plantation. (R. U. S.)

ERMINE, an alternative name for the stoat (*Putorius ermineus*), applicable in its proper sense only when the animal is in its white winter coat. This animal measures 10in. in length exclusive of the tail, which is about 4in. long, and bushy towards the point. The fur in summer is reddish brown above and white beneath, changing in the winter of northern latitudes to snowy whiteness, except at the tip of the tail, which at all seasons is black. In Scottish specimens this change in winter is complete, but in those found in southern England, it is usually only partial. The white colour is protective; it also retains heat better than a dark covering. The colour change seems to be due, not to a moult, but to phagocytes devouring the pigment-bodies of the hair. *See* further the articles COLOURS OF ANIMALS and PHAGOCYTOSIS.

BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

THE ERMINE, OR STOAT

This animal has a greatly valued fur, which in summer is reddish brown, changing in winter, in the north, to snow white, all except the tail, which remains black

The species is a native of the temperate and subarctic zones of the Old World, and is represented in America by a closely allied form. It inhabits thickets and stony places, and frequently makes use of the deserted burrows of moles and other underground mammals. It feeds on rats, water-rats and rabbits, which it pursues with pertinacity and boldness. It takes readily to water, and will even climb trees in pursuit of prey. The female brings forth five young ones about the beginning of summer. The winter coat of the ermine forms one of the most valuable of commercial furs, and is imported in enormous quantities from Norway, Sweden, Russia, and Siberia. (*See* FUR; FUR-BEARING ANIMALS.)

ERMINE STREET. Documents and writers of the 11th and succeeding centuries occasionally mention four "royal roads" in Britain—Icknield Street, Erning or Ermine Street, Watling Street and Foss Way—as standing apart from all other existing roads and enjoying the special protection of the king. Unfortunately these authorities are not at all agreed as to their precise course; the roads themselves do not occur as specially privileged in actual legal or other practice, and it is likely that the category of Four Roads is the invention of a lawyer or an antiquary. The names are, however, attested to some extent by early charters which name them among other roads, as boundaries. From these charters we know that Icknield Street ran along the Berkshire downs and the Chilterns, that Ermine Street ran more or less due north through Huntingdonshire, that Watling Street ran north-west across the midlands from London to Shrewsbury, and Foss diagonally to it from Lincoln or Leicester to Bath and mid-Somerset. This evidence only proves the existence of these roads in Saxon and Norman days. But they all seem to be much older. Icknield Street is probably a prehistoric ridgeway along the downs, utilized perhaps by the Romans near its eastern end, but in general not Roman.

Ermine Street coincides with part of a line of Roman roads leading north from London through Huntingdon to Lincoln. This line is followed by the Old North Road through Cheshunt, Buntingford, Royston and Huntingdon to Castor near Peterborough; and thence it can be traced through lanes and byways past Ancaster to Lincoln. Watling Street is the Roman highway from

London by St. Alban's (Verulamium) to Wroxeter near Shrewsbury (Viroconium). Foss is the Roman highway from Lincoln to Bath and Exeter. Hence it has been supposed, and is still frequently alleged, that the Four Roads were the principal highways of Roman Britain. This, however, is not the case. Icknield Street is not Roman and the three roads which follow Roman lines, Ermine Street, Watling Street and Foss, held no peculiar position in the Romano-British road system (*see* BRITAIN: *Roman*). In later times, the names Ermine Street, Icknield Street and Watling Street have been applied to other roads of Roman or supposed Roman origin. This, however, is wholly the work of Elizabethan or subsequent antiquaries and deserves no credence.

The derivations of the four names are unknown. Icknield, Ermine and Watling may be from English personal names; Foss, originally Fos, seems to be the Lat. *fossa* in its occasional mediaeval sense of a bank of upcast earth or stones, such as the *agger* of a road. (F. J. H.)

ERMOLDUS NIGELLUS, a monk of Aquitaine, accompanied King Pepin, son of the emperor Louis I., on a campaign into Brittany in 824. Banished from Pepin's court on a charge of inciting the king against his father, he retired to Strasbourg, where he sought to regain the emperor's favour by writing a poem on his life and deeds. About 830 he obtained his recall, and has been identified with Hermoldus, who appears as Pepin's chancellor in 838. His poem, *In honorem Hludovici imperatoris,* consists of four books and deals with the life and exploits of Louis from 781 to 826. He also wrote two poems in imitation of Ovid.

His writings are published in the *Monumenta Germaniae historica, Scriptores,* Band 2 (Hanover, 1826 fol.); by J. P. Migne in the *Patrologia Latina,* tome 105 (Paris, 1844); and by E. Dümmler in the *Poëtae Latini aevi Carolini,* Band 2 (Berlin, 1881–1884). *See* W. O. Henkel, *Über den historischen Werth der Gedichte des Ermoldus Nigellus* (Eilenburg, 1876); W. Wattenbach, *Deutschlands Geschichtsquellen,* Band 1 (Berlin, 1904); and A. Potthast, *Bibliotheca historica,* pp. 430–431 (Berlin, 1896).

ERNE, name of a river and two lakes in north-west Ireland. The river rises in Lough Gowna, Co. Longford, flows north through Lough Oughter, and then broadens into Upper Lough Erne, a shallow sheet of water 13 m. long, thickly studded with islands. It winds past the town of Enniskillen and enters Lough Erne, which is 18 m. long and 5 m. in extreme width. The island of Devenish is celebrated for its antiquarian remains (*see* ENNISKILLEN). The river then runs westward to Donegal bay, with falls at Ballyshannon (*q.v.*). The area of the Erne basin is *c.* 1,600 sq.m., and the length of the Erne valley *c.* 70 m.

ERNEST I. (ERNST ANTON KARL LUDWIG), duke of Saxe-Coburg-Gotha (1784–1844), son of Francis, duke of Saxe-Coburg-Saalfeld, was born on Jan. 2, 1784. At the time of his father's death (Dec. 9, 1806) the duchy of Coburg was occupied by Napoleon, and Ernest did not come into his inheritance till after the Peace of Tilsit (July 1807). He threw himself with vigour into the war of liberation against the French. After the battle of Leipzig he was given the command of the V. army corps and reduced Mainz by blockade; he also commanded the Saxon troops during the campaign of 1815. At the congress of Vienna he received the principality of Lichtenberg which was slightly enlarged after the second peace of Paris. These territories he sold to Prussia in 1834. In 1826, in the division of the territories of the duchy of Saxe-Gotha which followed the death of its last duke (Feb. 1825), he had received the duchy of Gotha, ceding that of Saalfeld to the duke of Meiningen; and he now exchanged his style of Ernest III. of Saxe-Coburg-Saalfeld for that of Ernest I. of Saxe-Coburg-Gotha. In 1821 he had given a constitution to Coburg, but he did not interfere with the traditional system of estates at Gotha. He died on January 29, 1844. Under Duke Ernest the house of Coburg gained its great international position. His younger brother Leopold (*q.v.*) became king of the Belgians; his brother Ferdinand (b. 1785) married the wealthy princess Antoinette von Kohary (1816) and was the father of the duchess of Nemours and of the future King Ferdinand of Portugal. Of his sisters, Antoinette (1779–1824) married Duke Alexander of Württemberg; Juliane [Alexandra Feodorovna] (1781–1860) married the Russian tsarevitch Constantine, from whom she was, however, divorced in 1820; and Victoria (1786–1861), wife of Edward Augustus, duke of Kent, became the mother of Queen Victoria of England. Duke Ernest was twice married: (1) in 1817 to Louise, daughter of Duke Augustus of Saxe-Gotha, whom he finally divorced in 1826; (2) in 1831 to Maria, daughter of Duke Alexander of Württemberg. Of his sons, by his first wife, Ernest succeeded him in the duchy, and Albert married Queen Victoria (*see* ALBERT, FRANCIS CHARLES, etc).

ERNEST II., duke of Saxe-Coburg-Gotha (1818–1893), was born at Coburg on June 21, 1818, the eldest son of Duke Ernest I., whom he succeeded in 1844. His own character and the influence of the king of the Belgians made him one of the most liberal princes in Germany. He was able to bring to a satisfactory conclusion disputes with the Coburg estates. In 1848 he anticipated the demands of the people of Gotha for a reform, and in 1852 introduced a new constitution by which the administration of his two duchies was assimilated in many points. His greatest services to Germany were performed during the years of reaction after 1849; almost alone among the German princes he remained faithful to the Liberal and National ideals, and he allowed his dominions to be used as an asylum by the writers and politicians who had to leave Prussia and Saxony. The marriage of his niece, the English princess Victoria with Frederick, the heir to the Prussian throne, caused the Conservative party to look with increased suspicion on the Coburg influence. After 1860 he became the chief patron and protector of the *National Verein,* and allowed his court to become the centre of the rising national agitation. In 1862 he agreed that in war his troops should be placed under the command of the king of Prussia. The democratic leanings of the Coburg court, which were shared by the crown prince Frederick, were a serious embarrassment to Bismarck. The opposition was accentuated when the duke allowed his dominions to be used as the headquarters of the agitation in favour of Frederick, duke of Augustenburg, who claimed the duchies of Schleswig and Holstein, and it was at this time that Bismarck is reported to have said that if Frederick the Great had been alive the duke would have been in the fortress of Spandau. In 1863 he was present at the *Fürstentag* in Frankfort, and from this time was in more frequent communication with the Austrian court, where his cousin Alexander, Count Mensdorff, was minister. But in 1866 he at once placed his troops at the disposition of Prussia; Bismarck had in an important letter explained to him his policy and tactics. The Hanoverian army, in its attempt to march south and join the Bavarians, had to pass through Thuringia, and the battle of Langensalza was fought in the immediate neighbourhood of Gotha. His troops took part in the battle, which ended in the rout of the Prussians, the duke, who was not present during the fight, in vain attempting to stop it.

With the year 1866 the political rôle which Ernest had played ended, but he quoted with great satisfaction the words used in 1871 by the emperor William at Versailles, that "to him in no small degree was due the establishment of the empire." He was a man of varied tastes, a good musician—he composed several operas and songs—and a keen sportsman. He died at Reinhardsbrunn on Aug. 22, 1893. In 1842 the duke married Alexandrine, daughter of the grandduke of Baden; there were no children by this marriage and the succession to Saxe-Coburg-Gotha passed therefore to the children of his younger brother Albert, the British prince consort, whose marriage contract precluded him from succeeding to the dukedom; the duchy came therefore to his second son, Alfred, duke of Edinburgh (1844–1900). *See* ALBANY, DUKES OF; SAXE-COBURG-GOTHA.

Duke Ernest published his memoirs, *Aus meinem Leben und aus meiner Zeit* (3 vols., 1887–89, Eng. trans. by P. Andreae, 1888–90).

See also Sir T. Martin, *Life of H.R.H. the Prince Consort* (1875–80); Hon. C. Grey, *Early Years of the Prince Consort* (1867); A. Ohorn, *Herzog Ernst II., ein Lebensbild* (Leipzig, 1894); and E. Tempeltey, *Herzog Ernst von Koburg und das Jahr 1866* (1898).

ERNEST AUGUSTUS (1771–1851), king of Hanover and duke of Cumberland fifth son of George III., King of England, was born at Kew on June 5, 1771. He studied at Göttingen, entered the Hanoverian army, and served as a leader of cavalry

when war broke out between Great Britain and France in 1793. When Hanover withdrew from the war in 1795 he returned to England, being made lieutenant-general in the British army in 1799. In the same year he was created duke of Cumberland and Teviotdale and granted an allowance of £12,000 a year. A stanch Tory, the duke objected to all proposals of reform, especially to the granting of any relief to the Roman Catholics, and had great influence with his brother the prince regent, afterwards King George IV., in addition to being often consulted by the Tory leaders. In 1810 he was severely injured by an assailant, probably his valet Sellis, who was found dead; and subsequently two men were imprisoned for asserting that the duke had murdered his valet. Recovering from his wounds, Cumberland again proceeded to the seat of war; as a British field-marshal, he was in command of the Hanoverian army during the campaigns of 1813 and 1814, being present, although not in action, at the battle of Leipzig. In May 1815 Ernest married his cousin, Frederica (1778–1841), daughter of Charles II. duke of Mecklenburg-Strelitz and widow of Frederick, prince of Solms-Braunfels, a union which was very repugnant to his mother Queen Charlotte, and was disliked in England, where the duke's strong Toryism had made him unpopular. The duke resented the refusal of parliament to increase his allowance from £18,000 to £24,000 a year, and retired for some years to Berlin. On the accession of George IV., with whom he had considerable influence, he returned to England. When William IV. died in June 1837, the crowns of Great Britain and Hanover were separated; and Ernest, as the nearest male heir of the late king, became king of Hanover. He cancelled the constitution which William had given in 1833, and the constitution which he sanctioned in 1840 was characteristic of his own illiberal ideas. His reign was a stormy one, and serious trouble between king and people had arisen when he died at Herrenhausen on Nov. 18, 1851 (*see* HANOVER: *History*). Ernest, who is generally regarded as the ablest of the sons of George III., left an only child, George, who succeeded him as king of Hanover.

See C. A. Wilkinson, *Reminiscences of the Court and Times of King Ernest of Hanover* (1886); von Malortie, *König Ernst August* (Hanover, 1861); and the various histories of Great Britain and Hanover for the period.

ERNEST AUGUSTUS, DUKE OF CUMBERLAND (1845–1923), only son of George V. of Hanover (*q.v.*), who was deposed in 1866, following the events of the Seven Weeks' War, was born at Hanover on Sept. 21, 1845. He was a grandson of the Ernest Augustus, king of Hanover noticed above. Ernest Augustus lived at Gmünden, and after his father's death maintained his claim to the Hanoverian throne. He bore the titles of duke of Cumberland, and duke in Brunswick and Lüneburg. He married Princess Thyra of Denmark. When William, duke of Brunswick, died (1884) without issue, Ernest Augustus claimed the duchy as the next heir, but the Federal diet refused to sanction his accession to the ducal throne because he persisted in the Hanoverian claim. Brunswick was therefore placed under a regency. In 1902 he expressly stated to the German emperor his acquiescence in the imperial régime, and thenceforward received the income from his inheritance. He resigned his claim to the duchy of Brunswick in favour of his son Ernest Augustus in 1906. The decision of the Federal Council was, however, reaffirmed in 1907.

Prince Ernest Augustus presently entered the Prussian army, and the difficulties, in so far as Brunswick was concerned, were ended by his marriage (May 24, 1913), to the only daughter of Wilhelm II., Victoria Louise. He then asked for a reversal of the former decisions of the Federal Council. The Council agreed on Oct. 27 to the prince's accession, and on Nov. 3 the young duke and duchess made their State entry into Brunswick. The decision was attacked in the *reichstag* because the duke of Cumberland had never renounced the throne of Hanover. Ernest Augustus, duke of Brunswick, abdicated, with other German princes in 1918. His father died at Gmünden on Nov. 14, 1923.

ERNESTI, JOHANN AUGUST (1707–1781), German theologian and philologist, was born Aug. 4, 1707, at Tennstädt in Thuringia. He was educated at the celebrated Saxon cloister school of Pforta, and at the universities of Wittenberg and Leipzig. After minor appointments, he was named professor *extraordinarius* of ancient literature in the university of Leipzig (1742), professor *ordinarius* of rhetoric (1756), and professor *ordinarius* in the faculty of theology (1759). He died at Leipzig on Sept. 11, 1781.

To Ernesti and to Gesner is due the credit of having formed, by discipline and by example, philologists greater than themselves, and of having kindled the national enthusiasm for ancient learning. In his *Institutio Interpretis N. T.* (1761), Ernesti admits in the sacred writings as in the classics only one acceptation, and that the grammatical, convertible into the logical and historical. Consequently he censures all mystical interpretation as well as extreme rationalism. At the same time, as a dogmatician, he clung to the traditions of the Lutheran Church.

His chief works are:—*Initia doctrinae Solidioris* (1736); editions, mostly annotated, of Xenophon's *Memorabilia* (1737), Cicero (1737–39), Suetonius (1748), Tacitus (1752), the *Clouds* of Aristophanes (1754), Homer (1759–64); *Antimuratorius sive confutatio disputationis Muratorianae de rebus liturgicis* (1755–58); *Neue theologische Bibliothek*, vols. i. to x. (1760–69); *Institutio interpretis Nov. Test.* (3rd ed., 1775); *Neueste theologische Bibliothek*, vols. i. to x. (1771–75); *Opuscula oratoria* (1762); *Opuscula philologica et critica* (1764); *Opuscula theologica* (1773).

ERNLE, ROWLAND EDMUND PROTHERO, 1ST BARON (1852–), British agriculturist and writer, was born in Clifton-on-Teme on Sept. 6, 1852, son of Canon Prothero, rector of Whippingham. He was educated at Marlborough and Balliol college, Oxford, and became a fellow of All Souls. From 1894 to 1899 Prothero edited *The Quarterly Review*. Twenty years as chief agent to the duke of Bedford gave him a thorough insight into agricultural questions. In 1913 he was a member of the royal commission on railways, and sat on the departmental committees on the home production of food (1914) and the increased price of commodities (1915). He entered parliament for Oxford university in 1914, and was president of the Board of Agriculture under Lloyd George, 1916–19, when he resigned and was raised to the peerage.

Among his works are *Pioneers and Progress of English Farming* (1888); *Life and Correspondence of Dean Stanley* (1893); *Letters of Edward Gibbon* (1896); *Letters and Journals of Lord Byron* (1898–1901); *Psalms in Human Life* (1903); *The Pleasant Land of France* (1908); *English Farming, Past and Present* (1912); and *The Land and Its People* (1925).

ERNST, HEINRICH WILHELM (1814–1865), German violinist and composer, was born at Brünn, Moravia, on May 6, 1814, and was educated at the conservatorium of Vienna, studying the violin under Joseph Böhm and Joseph Mayseder, and composition under Ignaz von Seyfried. In 1832 he went to Paris, where he formed an intimacy with Stephen Heller, which resulted in their charming joint compositions—the *Pensées fugitives* for piano and violin. In 1843 he paid his first visit to London. The impression which he then made as a violinist was more than confirmed in the following year, when his rare powers were recognized by the musical public. After a long illness, he died at Nice, Oct. 8, 1865. As a violinist Ernst was distinguished by his great mastery of technique, loftiness of conception, and intensely passionate expression. He wrote, in addition to many fantasias and salon pieces for the violin, a concerto (F sharp minor) of great technical difficulty which is still sometimes heard, and two string quartets.

ERNST, PAUL (1866–), German author, was born at Elbingerode on March 7, 1866, and educated locally and at the universities of Göttingen, Tübingen, Berlin and Berne. After early experiments in journalism, farming and the local administrative service, he later devoted himself exclusively to literature. Attached for a time to the *Düsseldorfer Schauspielhaus*, he wrote many dramas: *Lumpenbagasch and Im Chambre séparée* (1898), *Demetrios* (1905); *Das Gold* (1906); *Canossa* (1908); *Brunhild* (1909); *Ariadne auf Naxos* (1914); *Chriemhild* (1918), which, however, suffer from a certain stiffness and artificiality. He also wrote many narrative poems and short stories, and in 1924 commenced to publish his great classical epic, *Das Kaiserbuch*. He was most at home, however, in the short story, in which he imitated the manner of the Italian renaissance with great dexterity

(*Sechs Geschichten* [1900]; *Prinzessin des Ostens* [1902]; *Hochzeit* [1913]; *Die Taufe* [1916], etc.). His style is less well adapted to the novel, but his semi-autobiographical *Der Schmale Weg zum Glück* (1903) met with some success. Ernst was the leading representative of the German neo-classic school, and as such strongly opposed to the expressionism of his day. His theories, which he evolved scientifically and followed conscientiously, are set out in his *Der Weg zur Form* (1906), a very interesting literary manifesto. Two political works, *Der Zusammenbruch des Marxismus* (1918) and *Der Zusammenbruch des deutschen Idealismus* (1920) show the evolution of his mind from Socialism to Conservatism. His collected works (15 vols.) were published 1916–22.

See R. Faesi, *Paul Ernst und die neuklassizischten Bestrebungen im Drama* (1913); W. Mahrholz, *Paul Ernst* (1917).

ERODE, a town of British India, in the Coimbatore district of Madras, on the right bank of the river Cauvery, here crossed by a railway girder bridge. Pop. (1921) 22,911. Here the South Indian railway joins the South-Western line of the Madras railway, 243 m. from Madras. The town is a centre of trade and industry, dealing in rice, cotton, saffron, chillies, etc. There is an industrial school.

EROS (ĕr′ŏs), in Greek mythology, god of love. He is not mentioned in Homer; in Hesiod (*Theog.* 120) he is a primeval god, son of Chaos. This cosmic Eros is further elaborated in Orphic cosmogony. A cult of Eros existed at Parium and at Thespiae in Boeotia. He was god, not simply of passion, but of fertility. Later mythology makes him the son of Aphrodite by Zeus, Ares, or Hermes. His brother is Anteros, the god of mutual love; he is sometimes described as the opponent of Eros. The chief associates of Eros are Pothos and Himeros (longing and desire); he himself is in constant attendance on Aphrodite. Later writers (Euripides being the first) assumed the existence of a number of Erotes (like the Roman Amores and Cupidines). Plato and other philosophers allegorize Eros. In Alexandrian poetry he degenerates into a mischievous child, an idea possibly connected with the importance of children in magic and cult. (*See* also CUPID.)

In art Eros is represented as a beautiful youth or a baby archer. The rose, the hare, the cock, and the goat are frequently associated with him. The most celebrated statue of him was at Thespiae, the work of Praxiteles.

EROS, an asteroid of exceptional interest owing to its close approaches to the earth. In 1898 the number of known asteroids had mounted up to over four hundred, and as there was considerable monotony in their appearance and in the nature of their orbits many astronomers were beginning to question whether the time spent in searching for them and in calculating their movements was worth while. Then came a discovery, which might never have been made had the search been abandoned, that gave full compensation for all the time thus spent. On Aug. 13, 1898, Dr. G. Witt, at the Urania Observatory, Berlin, discovered photographically a faint asteroid of the 11th magnitude that was retrograding at the unprecedented rate of half a degree per day; this unusual motion caused it to be widely observed, and after a short interval Dr. Berberich of the Berlin Rechen-Institut published elements which proved to be very near the truth. The new body was designated at first 1898 DQ, but subsequently received the permanent number 433 and the name Eros (masculine names are given only to asteroids with very exceptional orbits, feminine ones being the rule).

Its period of revolution is 643 days, as compared with 687 for Mars. It was already known that a few asteroids come nearer to the sun at their perihelia than Mars at its aphelion; but Eros's *mean* distance is considerably less than that of Mars. As its eccentricity is 2/9, its least distance from the sun is only 1·13 astronomical units, so that it can approach the earth within 14 million miles, a much smaller distance than that of any other planetary body except the moon. The distance is rendered less by the fact that the point where Eros crosses the plane of the earth's orbit (descending node) is distant only 2¼° from the perihelion point; since the orbit is inclined some 10¾° to that of the earth, the least distance would be twice as great if the node were 90° away from the perihelion.

Unfortunately very near approaches of Eros to the earth are rare; they occur only when the planet passes perihelion about the date Jan. 22, of any year. It was unlucky that the conditions were the most favourable possible in Jan. 1894, 4½ years before the discovery; indeed subsequent examination of the immense stores of photographic plates exposed at Harvard College Observatory revealed 17 images of Eros at the opposition of 1893–94, and four images on plates taken at Arequipa, Peru, at the opposition of 1896. These images were used to give a better determination of the orbit, but the opportunity was missed of obtaining observations for the solar parallax.

The synodic period of Eros (that is, the average interval between one opposition and the next) is 845½ days, or two years and 115 days. Three synodic periods fall short of seven years by about three weeks; it follows that there was an approach to favourable conditions at the opposition at the end of 1900; and a parallax campaign was carried on at that time at the leading observatories of the northern hemisphere, the southern hemisphere being excluded owing to the high north declination of Eros (*see* article PARALLAX). Another very favourable opposition will occur in 1931. A convenient measure of the value of an opposition for parallax purposes is given by the number of days that elapses between the planet's passage through perihelion and the earth's passage through the longitude of that perihelion.

The following figures are from *Monthly Notices* of the Royal Astronomical Society for Feb. 1901; it gives the interval in days, the minus sign indicating that the planet comes first to the longitude, the plus sign that the earth comes first:— 1894, −0·40 days; 1901, +17·42; 1923–24, −23·24; 1931, −7·65; 1938, +7·95; 1945, +23·53; 1968, −17·13; 1975, −1·54; 1982, +14·05. These are all the oppositions up to the year 2000, for which the interval is less than 24 days. Dr. Witt's later value for 1931 is −5·91 days, so that the table needs a correction of +1¾ days at that point. The correction in 1975 may be about twice as great, which would change the sign of the interval without greatly altering its magnitude. It will be seen that 81 years brings back a recurrence of conditions, this being equal to 46 revolutions of Eros.

It will be seen that the 1931 apparition is the best one till 1975 (though 1938 is not much inferior to it) and extensive preparations are already being made to utilize it to the utmost; these include accurate observations of many stars near the planet's track, to serve as points of reference. A valuable by-product of the parallax investigation is a determination of the mass of the moon; the moon causes the earth to describe a small circle the radius of which is about 3,000 miles in a monthly period; this motion produces a wave in the apparent motion of Eros, with the same period. A peculiarity in the apparent motion of Eros at a perihelion opposition is that, unlike most of the superior planets, it does not retrograde, since its linear velocity, even when multiplied by the cosine of its inclination, exceeds that of the earth. Eros was unique in this respect when discovered, but Albert, Alinda, and Ganymede have since been found to share the peculiarity.

The motion of Eros, as seen from Mars, would be very curious; each planet might witness a transit of the other across the sun, while at other times each would see the other in the polar constellations. Owing to the large eccentricities of their orbits, each would in turn gain on the other in longitude. Their synodic period, or average interval between their conjunctions, is 27·6 years; but the unequal rates of motion would cause large variations in the intervals. The least distance of Mars from Eros is about 21 million miles, half as great again as Eros's least distance from the earth. Owing, however, to the slow secular movements of nodes and perihelion points, there must have been times in the distant past when very close approaches of Eros and Mars were possible; and it has been conjectured that Mars was responsible for introducing Eros into its present orbit at such an encounter. While this is possible, Eros's small perihelion distance stands less in need of explanation since it has been found to be common to three other

planets (Albert, etc.).

The perturbations of Eros by the earth are very considerable. Prof. H. N. Russell published some computations about them in *Astron. Journ.* Nos. 483, 484. The largest term is $747'' \sin (7g - 4g')$ where g, g' are the mean anomalies of Eros, and the earth. The apparent shift in the position of Eros is magnified by its proximity, and the total displacement from one extreme to the other may amount to nearly three degrees; this shift will in time give a very accurate value of the earth's mass in terms of that of the sun, and hence of the sun's distance. But the period of the term is 41½ years, and the method will scarcely reach its full efficiency till two or three of these periods have elapsed. However, in 1921 Herr Noteboom published a determination of the sun's parallax by this method, for which he found the small probable error of $\cdot 001''$, his value being $8'' \cdot 799$. Prof. Russell also indicated the principal terms of the perturbations of Eros by Mars; the three largest, omitting one of very long period, have coefficients $11''\cdot 59$, $22''\cdot 81$, $11''\cdot 85$, and periods 40·8 years, 78·0 years and 85·5 years. The period of the first is so close to that of the large earth-term as to require a long interval to elapse before they can be separated.

The diameter of Eros is conjectured to be about 17 miles, assuming its albedo to be the same as that of Pallas. It appears somewhat brighter than the seventh magnitude at the most favourable oppositions, and somewhat fainter than the 11th at the most unfavourable ones; its mass would be 1/167,000,000 of the earth's, assuming its density equal to that of the moon. Its angular diameter may be $\frac{1}{4}''$ in Jan. 1931, an amount that would be measurable with a large interferometer. Such measures might also decide whether the planet's outline is circular or irregular; there appears to be no reason to expect such small bodies to be spherical, since gravity would be weak compared with cohesion. The fact that the light of Eros shows irregular variability lends colour to the hypothesis of non-sphericity. In Feb. 1901 the light-range exceeded a magnitude; the period being 5 hours 16 minutes; there were two unequal maxima and minima in this period, but three months later the light-variation almost disappeared. The variation was noticed again in 1903, but was absent in 1907. It is suggested in explanation that the axis of the planet is highly inclined; when the pole of rotation is central on the disc there would be no light-variation. It may also be noted that if the axis of rotation were not a principal axis it would shift within the body.

Eros will be easily seen with binoculars at the beginning of 1931. The nearest approach to the earth, 16½ million miles, is near the midnight between Jan. 30 and 31. (A. C. D. C.)

EROSION OF LAND. The process of removal of portions of the earth's crust by natural agencies, of which the most important is water. The wastage of the sea coast, or coast erosion, is described in the article COAST PROTECTION AND RECLAMATION; it is brought about in the main by the action of the sea waves but also, in part, by the disintegration or degradation of cliffs by atmospheric agents such as rain and frost and by tidal scour. In rivers and estuaries the erosion of banks is caused by the scouring action of the river stream, particularly in times of flood and, in the case of estuaries, also by the tidal flow on the ebb tide when river and tide-water combine in their erosive action. (*See* RIVER ENGINEERING.) The land surface generally is subjected to a continuous process of erosion by the action of rain, melting snow, ice and frost, the resulting detritus and sediment being carried by small streams into the rivers and thence to the ocean (*see* GEOLOGY). In some arid and desert tracts wind has an important effect in bringing about the erosion of rocks by driving sand; and the surface of sand dunes, where not held together and protected by vegetation, is subject to erosion and change by the drifting of blown sand.

ERPENIUS (original name VAN ERPE), **THOMAS** (1584–1624), Dutch Orientalist, was born at Gorcum, in Holland, on Sept. 11, 1584. He studied at Leiden, and by the advice of Scaliger took up oriental languages whilst taking his course of theology. He afterwards travelled in England, France, Italy and Germany. During his stay at Paris he contracted a life-long friendship with Casaubon and took lessons in Arabic from an Egyptian, Joseph Barbatus, otherwise called Abu-dakni. At Venice he perfected himself in the Turkish, Persic and Ethiopic languages. After a long absence, Erpenius returned to his own country in 1612, and in 1613 was appointed professor of Arabic and other oriental languages, Hebrew excepted, in the University of Leiden. There he caused new Arabic characters to be cut at a great expense, and erected a press in his own house. In 1619 the curators of the University of Leiden instituted a second chair of Hebrew in his favour. He was preparing an edition of the Koran with a Latin translation and notes, and was projecting an oriental library, when he died on Nov. 13, 1624. Among his works may be mentioned his *Grammatica Arabica,* published originally in 1613 and often reprinted; *Rudimenta linguae Arabicae* (1620); *Grammatica Ebraea generalis* (1621); *Grammatica Chaldaica et Syria* (1628); and an edition of Elmacin's *History of the Saracens.*

ERROLL (or ERROL), **FRANCIS HAY,** 9TH EARL OF (d. 1631), Scottish nobleman, was the son of Andrew, 8th earl, and of Lady Jean Hay, daughter of William, 6th earl. He succeeded to the earldom (cr. 1453) in 1585, was early converted to Roman Catholicism, and as the associate of Huntly joined in the Spanish conspiracies against the throne of Elizabeth. An intercepted letter led to his denunciation as a rebel by the council in 1589. He engaged with Huntly and Crawford in a rebellion in the north of Scotland, but their forces surrendered at Aberdeen on the arrival of the king in April; and in July Erroll gave himself up to James, who refrained from exacting any penalty. In September he entered into a bond with Huntly for mutual assistance.

In 1590 he displeased the king by marrying, in spite of his prohibition, Lady Elizabeth Douglas, daughter of the earl of Morton. He was imprisoned on suspicion of complicity in the attempt made by Gray and Bothwell to surprise the king at Falkland in June 1592; and though he obtained his release, he was again proclaimed a rebel. After a failure to apprehend him in March 1593, Erroll and his companions were sentenced to abjure Romanism or leave the kingdom; and on their non-compliance were in 1594 declared traitors. On Oct. 3 they defeated at Glenlivet a force sent against them under Argyll; though Erroll himself was severely wounded, and Slains castle, his seat, razed to the ground. The rebel lords left Scotland in 1595. Erroll returned to Scotland secretly in 1596, and made his peace with the Kirk. In 1602 he was appointed a commissioner to negotiate the union with England. Between 1608 and 1611 he was in prison as an "obstinate papist." Erroll died on July 16, 1631, and was buried in the church of Slains.

See *The Erroll Papers* (Spalding Club Miscellany, vol. ii. 211); Andrew Lang, *Hist. of Scotland,* vol. ii.; *Hist. MSS. Comm. MSS. of Earl of Mar and Kellie;* D. Calderwood's *Hist. of the Church of Scotland;* John Spalding's *Memorials* (Spalding Club, 1850); *Treason and Plot,* by M. A. S. Hume (1901); *Collected Essays* of T. G. Law, ed. by P. H. Brown (1904).

ERROR. The words "error excepted" or "errors and omissions excepted" (contracted to "E.E.," "E. & O.E.") are frequently placed at the end of a statement of account or an invoice, so that the accounting party may reserve the right to correct any errors or omissions which may be subsequently discovered, or make further claims in respect of them. In mathematics, "error" is the deviation of an observed or calculated quantity from its true value. The calculus of errors leads to the formulation of the "law of error," which is an analytical expression of the most probably true value of a series of discordant values. (*See* MISTAKE; CONTRACT; PROBABILITY.) For the legal process known as a "writ of error," *see* WRIT and APPEAL.

ERSCH, JOHANN SAMUEL (1766–1828), the founder of German bibliography, was born at Grossglogau, in Silesia, on June 23, 1766, and studied at Halle. He was the author of many important bibliographical works and, with Johann Gottfried Gruber (*q.v.*), of the *Allgemeine Encyklopädie der Wissenschaften und Künste* (Leipzig, 1818, *seq.*) which he continued as far as the 21st volume. The accuracy and thoroughness of this monumental encyclopaedia make it still an important book of reference. Ersch died at Halle on Jan. 16, 1828.

ERSE or **IRISH,** the native language of Ireland (*q.v.*). *See* CELTIC LANGUAGES.

ERSKINE, HENRY (1746–1817), lord advocate of Scotland, the second son of the 10th earl of Buchan, and brother of the lord chancellor Erskine, was born in Edinburgh on Nov. 1, 1746. He was educated at the universities of St. Andrews, Glasgow and Edinburgh, and was admitted a member of the faculty of advocates in 1768. He was lord advocate in 1783 under Fox's and North's ministry, and again under Grenville in 1806. He retired in 1811 and died at Almondel, Linlithgowshire, on Oct. 8, 1817. Erskine's reputation will survive as the finest and most eloquent orator of his day at the Scottish bar; added to a charming forensic style was a most captivating wit, which, as Lord Jeffrey said, was "all argument, and each of his delightful illustrations a material step in his reasoning." Erskine was also the author of some poems, of which the best known is "The Emigrant" (1783).

See Lieut.-Col. A. Fergusson's *Henry Erskine* (1882).

ERSKINE, JOHN, of Dun (1509–1591), Scottish reformer, the son of Sir John Erskine, laird of Dun, was born in 1509, and was educated at King's College, Aberdeen. At the age of twenty-one Erskine was the cause—probably by accident—of a priest's death, and was forced to go abroad, where he came under the influence of the new learning. It was through his agency that Greek was first taught in Scotland by Petrus de Marsiliers at Montrose. Erskine was a close friend of George Wishart, the reformer, from whose fate he was saved by his wealth and influence, and of John Knox, whose advice openly to discountenance the mass was given in the lodgings of the laird of Dun. Erskine frequently acted as mediator both between the catholic and reforming parties, and among the reformers themselves. In 1560 he was appointed—though a layman—superintendent of the reformed church of Scotland for Angus and Mearns, and in 1572 he gave his assent to the modified episcopacy proposed by Morton at the Leith convention. He was more than once elected moderator of the general assembly (first in 1564), and he was amongst those who in 1578 drew up the *Second Book of Discipline.* From 1579 he was a member of the king's council. He died in 1591.

See the "Dun Papers" in the *Spalding Club Miscellany,* vol. iv. (1849), and the article in the *Dict. Nat. Biog.*

ERSKINE, JOHN, of Carnock (1695–1768), Scottish jurist, son of Lieut.-Colonel John Erskine, was in 1737 appointed professor of Scots law in the University of Edinburgh. In 1754 he published his *Principles of the Law of Scotland.* He retired from his chair in 1765, and the rest of his life was spent in the preparation of his great work, the *Institutes of the Law of Scotland,* which he did not live to publish. He died at Cardross, Perthshire, on March 1, 1768. Erskine's *Institutes* (1773; many later eds.) has always been esteemed of the highest authority on the law of Scotland. The *Principles,* being more concise and direct, retained its place as the text-book on Scots law, and was frequently re-edited.

ERSKINE, THOMAS, of Linlathen (1788–1870), Scottish theologian, was born on Oct. 13, 1788. He became in 1810 a member of the Edinburgh faculty of advocates, and belonged to the brilliant legal circle of the Edinburgh of that day, which included Cockburn, Jeffrey, Scott and others. In 1816 he succeeded to the family estate of Linlathen, near Dundee, and devoted himself to theology. As an interpreter of the mystical side of Calvinism and of the psychological conditions which correspond with the doctrines of Grace, Erskine excelled. He died at Edinburgh on March 20, 1870.

His principal works *Remarks on the Internal Evidence for the Truth of Revealed Religion* (1820), an *Essay on Faith* (1822), and the *Unconditional Freeness of the Gospel* (1828), have all passed through several editions, and have also been translated into French. Two vols. of his letters, edited by William Hanna, D.D., with reminiscences by Dean Stanley and Principal Shairp, appeared in 1877.

ERSKINE, THOMAS ERSKINE, 1st Baron (1750–1823), lord chancellor of England, was the third son of the 10th earl of Buchan, and was born in Edinburgh on Jan. 10, 1750. He was educated at the high school of Edinburgh and the grammar school at St. Andrews, and in 1764 became a midshipman. In 1768 he left the navy and bought a commission in the 1st Royals, but promotion here was no better; he married in 1770, the daughter of Mr. Moore, M.P. for Marlow. A chance interview with Lord Mansfield decided him to try the law, and he entered Lincoln's Inn in 1775. He read with Buller and Wood, and was called to the bar in 1778. He made an instant success, getting a brief at once, owing to the chance of his having been a sailor, for Baillie, accused of libel in a pamphlet on the management of Greenwich hospital. Erskine was the junior of five counsel; and it was his good fortune that the prolixity of his leaders consumed the whole of the first day, thereby giving the advantage of starting afresh next morning. He made use of this opportunity to deliver a speech of wonderful eloquence, skill and courage, which captivated both the audience and the court. The rule was discharged, and Erskine's fortune was made. He received, it is said, 30 retainers before he left the court. In 1781 he delivered another remarkable speech, in defence of Lord George Gordon—a speech which gave the death-blow to the doctrine of constructive treason.

In 1783, when the Coalition ministry came into power, he was returned to parliament as member for Portsmouth. He and Eldon made their maiden speeches together on Fox's India bill, and both were failures; Erskine was never a success in parliament. He became a K.C. in 1783, four and one-half years from his call, and was the first counsel to give up his circuit and only take special retainers. In 1783 he received a patent of precedence. His first special retainer was in defence of Dr. W. D. Shipley, dean of St. Asaph, who was tried in 1784 at Shrewsbury for seditious libel—a defence to which was due the passing of the Libel Act 1792, laying down the principle for which Erskine here unsuccessfully contended, that it is for the jury, and not for the judge to decide the question whether or no a publication is a libel. In 1789 he was counsel for John Stockdale, a bookseller, who was charged with seditious libel in publishing a pamphlet in favour of Warren Hastings, whose trial was then proceeding; and his speech on this occasion, probably his greatest effort, is a consummate specimen of the art of addressing a jury. Three years afterwards he brought down the opposition alike of friends and foes by defending Thomas Paine, author of *The Rights of Man*—holding that an advocate has no right, by refusing a brief, to convert himself into a judge. As a consequence he lost the office of attorney-general to the prince of Wales, to which he had been appointed in 1786; the prince, however, subsequently made amends by making him his chancellor.

In 1794 he conducted the defence in the Parliamentary Reform cases; he secured the acquittal in turn of Hardy, by a magnificent speech, of Home, Horne Tooke and Thelwall. The attorney-general then gave it up, and the other prisoners were discharged. This gained Erskine enormous popularity. In 1806 he was made lord chancellor in Grenville's ministry, for which he was totally unfitted. The rest of his life was unhappy; he never received office again, and he made his financial position worse by an imprudent second marriage. But in the defence of Queen Caroline he returned to his old eminence. On this he made his last speech in the House of Lords, and for his last few years he was again the popular idol. He died at Almondell, Linlithgowshire, on Nov. 17, 1823, of pneumonia, caught on the voyage to Scotland.

Erskine's great forensic reputation was, to a certain extent, a concomitant of the numerous political trials of the day, but it was also due to his impassioned eloquence and undaunted courage, which so often carried audience and jury and even the court along with him. As a judge he did not succeed; and it has been questioned whether under any circumstances he could have succeeded. For the office of chancellor he was plainly unfit. As a lawyer he was well read, but by no means profound. His strength lay in the keenness of his reasoning faculty, in his dexterity and the ability with which he disentangled complicated masses of evidence, and above all in his unrivalled power of fixing and commanding the attention of juries. He was probably the greatest advocate the English bar has ever seen.

In 1772 Erskine published *Observations on the Prevailing Abuses in the British Army,* a pamphlet which had a large circulation, and in later life, *Armata,* an imitation of *Gulliver's Travels.* His most noted speeches have repeatedly appeared in a collected form. *See* Campbell's *Lives of the Chancellors;* Moore's *Diaries;* Fergusson's *Henry Erskine* (1882); Dumerit's *Henry Erskine, a Study* (Paris, 1883); Lord Brougham's *Memoir,* prefixed to Erskine's *Speeches* (1847); Romilly's *Memoirs;* the *Croker Papers;* Lord Holland's *Memoirs.*

ERUBESCITE: *see* BORNITE.

ERYSIPELAS—synonyms, *the Rose, St. Anthony's Fire*—an acute contagious disease, characterized by a spreading inflammation of the skin, caused by *streptococcus erysipelatis.* Erysipelas is endemic in most countries, and epidemic at certain seasons, particularly the spring of the year. The disease seems to depend in all cases upon the existence of a wound or abrasion. In the so-called idiopathic variety, of which *facial erysipelas* is the best known, the point of entry is probably an abrasion by the lachrymal duct.

The skin in a mild case of erysipelas is red and oedematous and may show small vesications. The edge of the patch is often raised and distinct and extends from day to day. As the disease advances the portions of skin first attacked become less inflamed and slight desquamation occurs. The inflammation in general disappears after a week or ten days, but recrudescences are common if the streptococcus is very virulent or the patient's resistance low; suppuration or even gangrene may occur. In such cases the local condition becomes subordinate to a general septicaemia. In all cases of erysipelas constitutional symptoms are severe, temperatures of 105°F. and delirium being common.

Although the termination is usually favourable, serious and occasionally fatal results follow from inflammation of the membranes of the brain, and in some rare instances sudden death has occurred from suffocation arising from oedema glottidis, the inflammatory action having spread into and extensively involved the throat. One attack of this disease, so far from giving protection, appears to leave the patient susceptible to others. A fatal form occasionally attacks new-born infants, particularly in the first four weeks of their lives. In epidemics of puerperal fever this form of erysipelas has been specially found to prevail.

The treatment of erysipelas is that of a severe bacterial toxaemia. Strength must be maintained and local applications may be soothing, but administration of antistreptococcus serum appears to be the rational treatment.

ERYTHRAE, one of the Ionian cities of Asia Minor, situated on a small peninsula stretching into the Bay of Erythrae, at an equal distance from the mountains Mimas and Corycus, and directly opposite the island of Chios. In the peninsula excellent wine was produced. The town was said to have been founded by Ionians under Knopos, son of Codrus. Never a large city, it sent only eight ships to the battle of Lade. The Erythraeans owned for a considerable time the supremacy of Athens, but towards the close of the Peloponnesian war they threw off their allegiance to that city. After the battle of Cnidus, however, they received Conon, and paid him honours in an inscription, still extant. The ruins include well preserved Hellenistic walls with towers, of which five are still visible. The acropolis (280 ft.) has the theatre on its north slope, and eastwards lie many remains of Byzantine buildings.

ERYTHRITE, the name given to (1) a mineral composed of a hydrated cobalt arsenate, and (2) in chemistry, a tetrahydric alcohol (*see* ERYTHRITOL). (1) The mineral has the formula $Co_3(AsO_4)_2 \cdot 8H_2O$, and crystallizes in the monoclinic system. It sometimes occurs as radially-arranged groups of brilliant crimson blade-shaped crystals. On exposure to light the colour and lustre deteriorate. Cleavage flakes are soft (H=2), sectile and flexible; specific gravity 2·95. The mineral is, however, more often found as an earthy encrustation with a peach-blossom colour, and in this form was early known as cobalt-bloom. It occurs as a product of alteration of smaltite ($CoAs_2$) and other cobaltiferous arsenides. The finest crystallized specimens are from Schneeberg in Saxony. The earthy variety has been found in Thuringia, Cornwall, Cobalt (Ont.) and some other places.

ERYTHRITOL is an alcohol, allied to the carbohydrates (*q.v.*), and having four alcoholic (hydroxyl groups)—a tetrahydric alcohol. It is also known by many synonyms; *e.g.*, butanesterol, erythrite, erythrol, erythromannite, erythroglucin and phycite. Its formula is $HO \cdot CH_2 \cdot CH(OH) \cdot CH(OH) \cdot CH_2 \cdot OH$. Erythritol crystallizes from water in large lustrous quadratic prisms having a sweet taste; it melts at 126° C and boils at 330° C.

In chemical constitution, erythritol is analogous with tartaric acid and like this acid exists in a racemoid form, resolvable into dextro- and levo-rotatory modifications, and in a non-resolvable inactive form which is identical with the naturally occurring variety found free in the alga *Protococcus vulgaris* and in combination with orsellinic acid in many lichens, especially in *Roccella tinctoria* and *montagnei.* Oxidation with dilute nitric acid furnishes erythrose which probably consists of a mixture of an aldose and a ketose (*see* CARBOHYDRATES). Further oxidation gives rise to mesotartaric acid. The four stereoisomeric forms of erythritol have been synthesised from divinyl (Griner 1893).

ERZBERGER, MATTHIAS (1875–1921), was born on Sept. 20, 1875, in Buttenhausen, in the Swabian Alps. Having entered the teaching profession, he soon became interested in politics. He joined the staff of the Stuttgart Catholic paper *Deutsches Volksblatt* and was elected member of the *Reichstag* at the age of 28. The Centre Party, to which he belonged, came into existence as a mainly religious association during the "Kulturkampf" (Bismarck's quarrel with the Catholic Church). When this particular dispute had been settled the Centre party assumed a rather complex political character. Erzberger, being anti-bureaucratic by temperament, began his career as a severe critic of the Colonial Office, whose chief spokesman, Dr. Helfferich, later on became his violent enemy. When Prince Bülow's incongruous Conservative-Liberal coalition broke down and the Centre Party again became a quasi-government party (1909), Erzberger had gained a leading position in its councils.

During the World War Erzberger built up a big organization to enlighten neutral opinion, addressing himself primarily to Catholics. He elaborated many plans for the reconstruction of Europe. He did not openly oppose submarine warfare, though he greatly feared America's entry into the war. In the summer of 1917 he realized that Austria was collapsing. He knew of the famous Czernin memorandum (April 12, 1917) and has even been falsely accused of having brought it to light. His insight into the Austrian situation and his disillusion about the submarine warfare made him take the initiative in bringing about the declaration of the *Reichstag* on July 19, which proclaimed Germany's intention to fight for a peace without annexations. His impetuous methods resulted in the overthrow of Bethmann Hollweg, who sympathized with the movement, and the accession to power of Michaelis, who supported the militarists and whose famous interpretation of the resolution destroyed such chances as the appeal might have had. Erzberger, never daunted by failure, played a part in the unsuccessful peace efforts of the Vatican.

Erzberger's great political chance came in Sept. 1918, when Prince Max of Baden formed a parliamentary government. Erzberger had outlined the programme for this coalition of National-Liberals, Liberals, Centrists and Socialists. He became secretary of State without portfolio. He was asked to lead the armistice commission when general headquarters insisted on an armistice. He did not succeed in getting terms based on the Wilson principles, which Germany had accepted. He has been held up to obloquy for this failure, but it may be doubted whether the most brilliant diplomatist would have fared better at the hands of a victorious general.

When Erzberger came home, the old régime had gone. He remained head of the armistice commission, but participated in the reorganization of the Centre Party, which gained 90 seats at the election of 1919. He entered the cabinet formed by Scheidemann, as minister without portfolio. When that Government, influenced by Brockdorff-Rantzau and the German delegation, desired to reject the peace terms, Erzberger dissented, distrusting the capacity of the German people to stand another prolonged strain, and fearing greatly for German unity. He pressed his point with his customary energy and perhaps, too, with some want of tact. He is alleged to have said openly that another government would sign the treaty, if Scheidemann refused, and it is quite possible that his utterances may have reassured the Allies of the small risk they ran when presenting an ultimatum (June 16). The Government did resign, and Erzberger became chancellor of the Exchequer in the Bauer Government formed by Socialists and Centrists which

signed the peace.

Up to that time the individual States had owned the railways and drawn the direct taxes, especially the income-tax; the Reich had to be satisfied mainly with indirect taxation. The wrangles between the States and the central authority had filled the pages of German history, the States always succeeding in holding their own. Erzberger took the railways for the Reich and established its control over taxation. He succeeded where Bismarck had failed. He organized an imperial inland revenue service and introduced a system of income and property taxes which, though somewhat socialistic in its main features, was the first real system of imperial finance Germany has had. He had realized as early as Sept. 1918 the necessity of creating a League of Nations and drafted a statute for it.

His activities during the World War, his participation in the armistice and the peace negotiations, and his financial policy made Erzberger the best hated man in Germany. His feud with the bureaucrats was of old standing. The capitalist classes hated him for his confiscatory financial legislation; and to the Prussian Protestant he was the international Catholic, who spoke with a broad Swabian accent. The federalists loathed him on account of his centralizing tendencies, and the militarists tried to make him the scapegoat for their want of success. All the enemies of the new order of things realized, however, that whatever his faults might be, he was a man of action and not a dreamer. He was the first political expert who knew how to lord it over the technical expert.

Karl Helfferich, a former secretary of State whose financial war policy Erzberger had strongly criticized, fathered these attacks in a pamphlet *Fort mit Erzberger,* in which Erzberger was accused of all sorts of petty underhand financial misdemeanours and even of having committed perjury. Erzberger sued Helfferich, but did not succeed in clearing himself as completely as the facts of the case probably warranted. He immediately resigned. The verdict assumed that he had committed perjury, but the same court, enquiring later on whether the facts established should lead to a public prosecution, came to a negative finding. It was then considered that in some way or other Erzberger would be completely rehabilitated. The feeling against him was so intense, however, that an abortive attempt upon his life was made during the proceedings. A few months after, when taking a holiday, he was foully murdered on Aug. 26, 1921, by Schulz and Tillessen, two members of secret associations, who got safely away to Hungary.

Erzberger was probably the most gifted man of action German democracy has so far produced. He acted with the light-hearted impetuosity of a child: there was no situation to which he did not consider himself equal. He quickly saw the main point, and when he saw it, he acted, being quite free from those mental impediments which so often paralyse intelligent men. He very often did not visualize the ultimate consequences of his actions, but this did not trouble him as he was quite sure that he could deal with them when they arose. His jaunty manner equally antagonized the deep thinker and the well-bred bureaucrat. He was often careless and inaccurate in details, for though details interested him greatly, he had not always a just sense of "values." Being rather insensitive himself, he often failed to consider other people's susceptibilities, and being simple though very shrewd, he was not a good judge of men and did not understand complicated minds, nor the impression he made upon them. He was a man of the people and he looked like it. As such he was loathed by all to whom a statesman must be "decorous." He was almost a genius. But he lacked the magnetism and the charm indispensable to a really great leader.

ERZERUM, the chief town of an important vilayet of the same name in Asiatic Turkey. Pop. (1927), 77,966. It is a military station and a fortress of considerable strategical value, closing the roads from Kars, Olti and other parts of the frontier. Several important routes from Trebizond and various parts of Anatolia converge towards it from the west. It is situated at the eastern end of an open bare plain, 30 m. long and about 12 m. wide, bordered by steep, rounded mountains and traversed by the Kara Su, or western Euphrates, which has its source in the Dumlu Dagh a few miles north of that town, which lies at an elevation of 6,250 ft. above sea-level, while the near hills rise to 10,000 ft. The scenery in the neighbourhood is striking, lofty bare mountains being varied by open plains and long valleys dotted with villages. Just east of the town is the broad ridge of the Deveboyun ("Camel's Neck"), across which the road passes to Kars. To the south is the Palanduken range, from which emerge numerous streams, supplying the town with excellent water. In the plain to the north the Kara Su traverses extensive marshes which afford good wildfowl shooting in the spring. The great altitude accounts for very severe winter cold, occasionally 10° to 25° below zero F, accompanied by blizzards (*tipi*) sometimes fatal to travellers overtaken by them. The summer heat is moderate (59° to 77°).

The town is surrounded by an earthen *enceinte* or rampart with some forts on the hills just above it, and others on the Deveboyun ridge facing east, the whole forming a position of considerable strength. The old walls and the citadel have disappeared. Inside the ramparts the town lies rather cramped, with narrow, crooked streets, badly drained and dirty; the houses are generally built of dark grey volcanic stone with flat roofs, the general aspect, owing to the absence of trees, being somewhat gloomy. The water-supply from Palanduken is distributed by wooden pipes to numerous public fountains.

Situated on the main road from Trebizond into north-west Persia, the town has always a large caravan traffic, principally of camels, but since the improvement of communications in Russia this has declined. A good carriage-road leads to the coast at Trebizond, the journey being made in five or six days. There are also roads to Kars, Bayazid, Erzingan and Kharput. Blacksmiths' and coppersmiths' work is better here than in most Turkish towns; horse shoes and brasswork are also famous. There are several tanneries, and Turkish boots and saddles are largely made. Jerked beef (*pasdirma*) is also prepared in large quantities for winter use. The plain produces wheat, barley, millet and vegetables. Wood fuel is scarce, the present supply being from the Tortum district, whence surface coal and lignite are also brought, but the usual fuel is *tezek* or dried cow-dung.

Erzerum is a town of great antiquity, and has been identified with the Armenian Garin Kalakh, the Arabic Kalikale, and the Byzantine Theodosiopolis of the 5th century, when it was a frontier fortress of the empire—hence its name *Erzen-er-Rum.* It was captured by the Seljuks in 1201, when it was an important city, and it fell into Turkish possession in 1517.

Battles of 1916. This brilliant feat of arms, which ended in the capture of the famous fortress by the Russians, and the rout of the Turks, on Feb. 16, 1916, is described under CAUCASUS, CAMPAIGNS IN THE, 1914–1918.

ERZGEBIRGE, a mountain chain extending from the Elbe to Elstergebirge on the frontier between Saxony and Bohemia (Ger. *Erz,* ore, *Gebirge,* mountain). Its length from east-north-east to west-south-west is about 80 m. and its average breadth about 25 miles. The southern slope is generally steep and rugged, forming in some places a perpendicular wall from 2,000 to 2,500 ft. in height; while the northern, divided at intervals by valleys of great fertility or wildly romantic, slopes gradually towards the great German plain. The central part of the chain forms a plateau of an average height of more than 3,000 ft., at the extremities of which are situated the highest summits of the range:—in the south-east the Keilberg (4,062 ft.); in the north-east the Fichtelberg (3,950 ft.); and in the south-west the Spitzberg (3,650 ft.). Between the Keilberg and the Fichtelberg, at about 3,300 ft., is Gottesgab, the highest town in Bohemia. Geologically, the Erzgebirge range consists mainly of gneiss, mica, schist and phyllite. It is famous for its mineral wealth, which consists principally of silver and lead, tin, nickel, copper and iron. Gold

is found in several places, and some arsenic, antimony, bismuth, manganese, mercury and sulphur. The Erzgebirge is celebrated for its lace manufactures, embroideries, silk-weaving and toys. The climate in winter is inclement in the higher elevations, and, as the snow lies deep until the spring, the range is a winter sports centre. In summer the air is bracing, and many health resorts have sprung into existence, among which are Kipsdorf, Bärenfels and Oberwiesenthal. The district is well served by railway and road communications.

The Elstergebirge, a range some 16 m. in length, in which the Weisse Elster has its source, runs south-west from the Erzgebirge to the Fichtelgebirge and attains a height of 2,630 ft.

ERZINGAN or **ERZINJAN** (*Arsinga* of the middle ages), the chief town of a vilayet of the same name in Asiatic Turkey. Pop. (1927) 51,789. It is a place of some military importance, with large barracks and military factories. It is situated at an altitude of 3,900 ft., near the western end of a rich well-watered plain through which runs the Kara Su or western Euphrates. It is surrounded by orchards and gardens, and is about a mile from the right bank of the river, which here runs in two wide channels crossed by bridges. One wide street traverses the town from east to west, but the others are narrow, unpaved and dirty, except near the Government buildings and the large modern mosque of Hajji Izzet Pasha to the north. The principal barracks, military hospital and clothing factory are at Karateluk on the plain and along the foot-hills to the north 3 m. off. The principal industries are the manufacture of silk and cotton and of copper dishes and utensils. The plain, almost surrounded by lofty mountains, is highly productive with many villages on it and the border hills. Wheat, fruit, vines and cotton are largely grown, and cattle and sheep are bred. Water is everywhere abundant, and there are iron and hot sulphur springs. The battle in which the sultan of Rum (1243) was defeated by the Mongols took place on the plain, and the celebrated Armenian monastery of St. Gregory, "the Illuminator," lies on the hills 11 m. S.W. of the town.

Erzingan occupies the site of an early town in which was a temple of Anaitis. It was an important place in the 4th century when St. Gregory lived in it. The district passed from the Byzantines to the Seljuks after the defeat of Romanus, 1071, and from the latter to the Mongols in 1243. After having been held by Mongols, Tatars and Turkomans, it was added to the Osmanli empire by Mohammed II. in 1473. In 1784 the town was almost destroyed by an earthquake.

ESAR-HADDON, Assyrian king, son of Sennacherib; before his accession to the throne he had also borne another name, Assur-etil-ilani-yukin-abla. At the time of his father's murder (the 20th of Tebet, 681 B.C.) he was commanding the Assyrian army in a war against Ararat. Esar-Haddon returned to Nineveh, and on the 8th of Sivan was crowned king. A good general, Esar-haddon was also an able and conciliatory administrator. His first act was to crush a rebellion among the Chaldaeans in the south of Babylonia and then to restore Babylon, the sacred city of the West, which had been destroyed by his father. The walls and temple of Bel were rebuilt, its gods brought back, and after his right to rule had been solemnly acknowledged by the Babylonian priesthood Esar-haddon made Babylon his second capital. A year or two later Media was invaded and Median chiefs came to Nineveh to offer homage to their conqueror. He now turned to Palestine, where the rebellion of Abdi-milkutti of Zidon was suppressed, its leader beheaded, and a new Zidon built out of the ruins of the older city (676–675 B.C.). All Palestine now submitted to Assyria, and 12 Syrian and 10 Cyprian princes (including Manasseh of Judah) came to pay him homage and supply him with materials for his palace at Nineveh.

But a more formidable enemy had appeared on the Assyrian frontier (676 B.C.). The Cimmerii (*see* SCYTHIA) under Teuspa poured into Asia Minor; they were, however, overthrown in Cilicia, and the Cilician mountaineers who had joined them were severely punished. It was next necessary to secure the southern frontier of the empire. Esar-haddon accordingly marched into the heart of Arabia, to a distance of about 900 m., across a burning and waterless desert, and struck terror into the Arabian tribes. At last he was free to invade Egypt, and led the main body of the Assyrian troops into Egypt on the 5th of Adar, 673 B.C. The desert was crossed with the help of the Arabian sheikh. Egypt seems to have submitted to the invader and was divided into 20 satrapies. Another campaign, however, was needed before it could be finally subdued. In 670 B.C. Esar-haddon drove the Egyptian forces before him in 15 days (from the 3rd to the 18th of Tammuz) all the way from the frontier to Memphis, thrice defeating them with heavy loss and wounding Tirhaka himself. In 668 B.C. Egypt again revolted, and while on the march to reduce it Esar-haddon fell ill and died on the 10th of Marchesvan.

ESAU, identified in Hebrew tradition with Edom, the eponymous ancestor of the Edomites, is the son of Isaac and Rebekah and elder twin brother of Jacob (Gen. xxv. 24–26). This narrative probably represents an earlier superiority of Edom over Israel, further attested by the view that Edom was a settled state before the Hebrew conquest of Canaan (Gen. xxxvi. 31 [P], Num. xx. 14 [E] etc.). The change in comparative status is reflected in two narratives of Genesis; in the one Esau sells his birthright to Jacob for a mess of red pottage (Gen. xxv. 21–34), whence the name Edom (=Red). According to the other, Jacob, in alliance with Rebekah, succeeded in cheating Esau out of the paternal blessing (Gen. xxvii.).

That Israel regarded Edom as living on a lower social order appears from Gen. xxv. 27, where Esau is a representative of the primitive "food-collector" or wandering hunter, Jacob a type of the "civilized" pastoral nomad. The greater fertility of Israelite territory is illustrated by the blessing of Jacob (Gen. xxvii. 26–29) and the corresponding curse of Esau (Gen. xxvii. 39–40).

ESBJERG, seaport, Denmark, on the west coast of Jutland. Its population grew from 13 in 1868 to 24,000 in 1928. The increase is due entirely to the construction of the harbour and railway in 1874. It is now an important commercial centre, with the only good harbour on the west coast of Jutland. It conducts an important passenger, mail and agricultural traffic with Harwich. There are stores for butter and eggs, export slaughteries and many factories. There is also a considerable fishing trade. The island of Fanoe, about 3 m. S.E., is a seaside resort.

ESCALANTE, a municipality (with administration centre and 11 *barrios* or districts) and port (sheltered by coral reefs) of the province of Negros Occidental, of the island of Negros, Philippine islands, on the north-east coast on Tañon strait, 329 m. from Manila. Pop. (1918), 28,934, of whom only 7 were whites. In 1918, it had 164 household industry establishments with output valued at 72,600 pesos. Of the 12 schools, 11 were public. The municipality was founded in 1860. The language is a dialect of Bisayan.

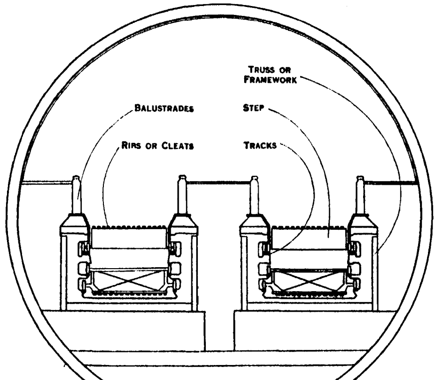
ESCALATORS. An escalator is a form of moving staircase in which motion in the plane of ascent is imparted to the stairs by mechanical means. Therefore a person standing on a step will be carried up or down according to the direction of motion. The early moving staircases were, in effect, inclined link belts forming inclined platforms without steps. As these are uncomfortable at any angle giving a reasonably high rate of ascent, moving staircases were later developed with steps, firstly by superimposing small articulated steps on the belts, and later by constructing unit steps running on tracks and attached to a chain; it was to these machines that the name "escalator" was given.

Four tracks are used, two being on each side of the step, and one of each pair for the back and the front. At the landings it is required that the steps form a level platform. This is done by arranging the supporting tracks so that they curve from the slope to the level in such a way that the horizontal distances between the tracks supporting the front and back of the step are always the same and equal to the distance between the wheels of the step running on these tracks; thus the top surface of each step is kept horizontal. In the early step machines the axes of wheels of each step lie in a horizontal plane and in later machines

in an inclined plane. The stairway runs between balustrades of wood or metal construction of form and shape varying according to local conditions. This balustrading commonly carries a flexible moving handrail, to assist the passenger in the ascent or descent. The tracks for the steps are carried in a truss or framework. The steps are attached to either one central or two side chains driven by sprocket wheels.

The earlier type step machines have a central chain driven at a point a little way down the slope and are provided with semi-circular tracks to transfer the chain and steps from the "go" to the "return" side. Some of the dependent weight of the chain and steps is relieved from the driving sprocket by introducing one or more sprockets, free to move and loaded by springs in the direction of the centre line of the machine and engaging the "go" and "return" sides of the chain, these sprockets being situated below the main driving sprocket and not supplied with any external power. In order to keep the chain and steps in contact with the curved track at the landing curves, the semi-circular tracks are loaded with weights. On the later machines the steps are arranged between two chains passing over sprockets at the ends of the machine. The upper sprocket runs in fixed bearings and is driven, while the lower runs free and a tension is kept on the main chains by a counterweight pulling the lower sprocket outwards, the bearings being movable. Safety devices are provided to deal with any irregular operation or breakage, such as broken chains, overspeed or reversal of the machine.

It is necessary to ensure that the user is transferred safely from the moving steps to the fixed landing. This is done on a step type machine with flat tread steps by arranging the steps to run flush with the landings and providing a diagonal barrier across the line of motion, thus ensuring that any person not stepping



TRANSVERSE SECTION OF TWO ESCALATORS, RUNNING 90 FT. PER MINUTE AT AN ANGLE OF 30°, CARRYING TWO PASSENGERS ON EACH STEP, TRANSPORTING 8,000 AN HOUR; MAKING THE OPERATING COSTS LOWER, THE CARRYING CAPACITY GREATER AND THE SERVICE QUICKER THAN WITH LIFTS

off sideways on to the landing is pushed off by contact with the barrier. An alternative construction which is more commonly used is to arrange ribs or cleats on the step tread at short distances apart and running from back to front of the steps. At the landings a metal comb is arranged with teeth projecting at a slight angle downwards towards the steps. The cleats on the steps move horizontally through the spaces between the teeth of the comb, and, since the plane of the top of the comb intersects the plane of the top of the cleats, the feet of any person not stepping off at the landing are slid gently up on to the stationary comb which joins the landing floor. This latter construction was also used on the earlier ramp type machines.

The usual linear speed, or speed of the steps up or down the incline for escalators, is 90–100ft. per min. corresponding, at the usual 30° angle of ascent, to a vertical speed of 45–50ft. per min., this representing a practicable operating speed both from the engineering and the passenger points of view. The limit of speed

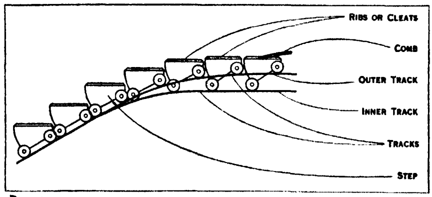


DIAGRAM OF ESCALATOR LANDING, SHOWING THE RELATION BETWEEN STEPS AND TRACKS AT LANDINGS AND THE METHOD OF CHANGING FROM STEPS TO FLAT PORTION, AND VICE VERSA

must depend on the landing arrangements and the necessity of catering for passengers of all ages and degrees of activity.

The escalator has an outstanding advantage over lifts or elevators in its continuity of action, and where vertical travel is associated with a displacement of the upper landing in relation to the lower, an escalator has the advantage of providing simultaneous movement in two dimensions; also the operating costs are lower. One escalator (one pair one up and one down) is equivalent in carrying capacity to several lifts, the equivalent number of lifts depending on size and speed.

The escalator has not yet been constructed for more than 60ft. vertical rise and this probably represents a practical operating limit. The lift is therefore a necessity for high rise services, unless two flights of escalators are used, with the consequent long time involved in the journey. Escalators are usually made of three sizes; *i.e.*, 2ft., 3ft. and 4ft., between balustrades. An escalator at any angle of 30° with the horizontal, running at 90ft. per min., carrying two passengers stationary on each step (4ft. wide), will transport 8,100 passengers per hour. If the passengers walk at the same time the capacity may be increased by 40%. Escalators are now in general use throughout the world in subways and elevated railways, industrial and factory buildings, restaurants, theatres and department stores. (W. S. G.-B.)

ESCANABA, a city of upper Michigan, U.S.A., on Little Bay de Noc, an inlet of Green bay (Lake Michigan); a port of entry and the county seat of Delta county. It is on Federal highways 2 and 41, and is served by the Chicago and Northwestern, the Escanaba and Lake Superior and the Soo Line railways, and by lake steamers in summer. The population was 13,103 in 1920 (22·5% foreign-born white) and was estimated locally at 15,000 in 1928. The city occupies a picturesque promontory 612ft. above sea-level. Its exhilarating climate and the attractions of the upper peninsula (varied and beautiful scenery, virgin forests and trout streams) make it a summer resort and a touring centre. It has 8m. of water front, and a natural deep-water harbour, open 8 months of the year, with four large, specially equipped docks for handling iron ore, of which over 6,000,000 tons are shipped annually. Escanaba is a division point of the Chicago and Northwestern railroad, which has large repair shops here. It is estimated that there are altogether 1,300 railroad employees in the city, and that the factories employ as many more. Among the important manufactures are lumber, maple flooring, veneers, charcoal, iron, chemicals, paper and cinder concrete blocks. There is a large tie-preserving plant. Escanaba was settled in 1863 and was chartered as a city in 1883. Since 1922 it has had a council-manager form of government.

ESCAPE, a verb meaning to get away from, especially from impending danger or harm, to avoid capture, to regain one's liberty after capture. As a substantive, "escape," in law, is the regaining of liberty by one in custody contrary to due process of

law (*see* RESCUE). "Escape" is used in botany of a cultivated plant found growing wild. The word is also used of a means of escape, *e.g.*, "fire-escape," and of a loss or leakage of gas, current of electricity or water.

ESCH A ALZ, a town of Luxembourg, on the river Alzette, near the frontier in the south-western corner of the country. It has important coal and iron mines and has light railway communications with the main lines serving Belgium, France and Germany. Pop. (1922), 21,208.

ESCHATOLOGY (the "doctrine of last things") is a theological term derived from the New Testament phrases "the last day" (ἐν τῇ ἐσχάτῃ ἡμέρᾳ John vi. 39) "the last times" (ἐπ' ἐσχάτων τῶν χρόνων I. Peter i. 20), "the last state" (τὰ ἔσχατα Matt. xii. 45) a conception taken over from ancient prophecy (Is. ii. 2; Mal. iv. 1). It was the common belief in the apostolic age that the second advent of Christ was near, and would give the divine completion to the world's history. The use of the term, however, has been extended so as to include all that is taught in the Scriptures about the future life of the individual as well as the final destiny of the world.

Eastern Religions.—There is a bewildering variety in the views of the future life and world held by different peoples. The future life may be conceived as simply a continuation of the present life in its essential features, although under conditions more or less favourable. It may also be thought of as retributive, as a reversal of present conditions so that the miserable are comforted, and the prosperous laid low, or as a reward or punishment for good or evil desert here. Personal identity may be absorbed, as in the transmigration of souls, or it may even be denied, while the good or bad result of one life is held to determine the weal or woe of another. The scene of the future life may be thought of on earth, in some distant part of it, or above the earth, in the sky, sun, moon or stars, or beneath the earth. The abodes of bliss and the places of torment may be distinguished, or one last dwelling-place may be affirmed for all the dead. Sometimes the good find their abiding home with the gods; sometimes a number of heavens of varying degrees of blessedness is recognized (*see* F. B. Jevons, *An Introduction to the History of Religion*, chs. xxi. and xxii., 1902; and J. A. MacCulloch's *Comparative Theology*, xiv., 1902).

Indian and Persian Contributions.—The Indian and the Persian contributions to eschatology deserve special mention. (1) A characteristic feature of Indian thought is the transmigration of the soul from one mode of life to another, the physical conditions of each being determined by the moral and religious character of the preceding. But deliverance from this cycle of existences, which is conceived as misery, is promised by means of speculation and asceticism. Denying the continuance of the soul, Buddhism affirmed a continuity of moral consequences (Karma), each successive life being determined by the total moral result of the preceding life. Its doctrine of salvation was a guide to, if not absolute non-existence, yet cessation of all consciousness of existence (Nirvana). Later Buddhism has, however, a doctrine of many heavens and hells. (2) In Zoroastrianism not only was continuance of life recognized, but a strict retribution was taught. Heaven and hell were very clearly distinguished, and each soul according to its works passed to the one or to the other. But this faith did not concern itself only with the future lot of the individual soul. It was also interested in the close of the world's history, and taught a decisive, final victory of Ormuzd over Ahriman, of the forces of good over the forces of evil. It is not at all improbable that Jewish eschatology in its later developments was powerfully influenced by the Persian faith.

Old Testament.—In the Old Testament we can trace the gradual development of an ever more definite doctrine of "the final condition of man and the world." This is regarded as the last stage in a moral process, a redemptive purpose of God. The eschatology of the Old Testament is thus closely connected with, but not limited by, Messianic hope, as there are eschatological teachings that are not Messianic. As the Old Testament revelation is concerned primarily with the elect nation, and only secondarily (in the later writings) with the individual persons composing it, the destiny of the nation stands in the foreground. The details of the development of the doctrine must be passed over, and its issue only be indicated. The contributions of the Old Testament to Christian eschatology embrace these features: "(1) the manifestation or advent of God; (2) the universal judgment; (3) behind the judgment the coming of the perfect kingdom of the Lord, when all Israel shall be saved and when the nations shall be partakers of their salvation; and (4) the finality and eternity of this condition, that which constitutes the blessedness of the saved people being the Presence of God in the midst of them—this last point corresponding to the Christian idea of heaven" (A. B. Davidson, in Hastings's *Bible Dictionary*, i. p. 738). This hope is for the people on this earth though transfigured.

To the individual it would seem at first only old age is promised (Is. lxv. 20; Zech. viii. 4), but the abolition of death itself is also declared (Is. xxv. 8). The resurrection which appears at first as a revival of the dead nation (Hos. vi. 2; Ez. xxxvii. 12–14), is afterwards promised for the pious individuals (Is. xxvi. 19), so that they too may share in the national restoration. Only in Daniel xii. 2 is taught a resurrection of the wicked "to shame and everlasting contempt" as well as of the righteous to "everlasting life." It was only at the Exile, when the nation ceased to be, that the worth of the individual came to be recognized, and the hopes given to the nation were claimed for the individual. Scholars, however, are not agreed how far any hope of individual immortality is found in the Old Testament. While some hold, others deny that the doctrine can be found in Ps. xvi. 9–11; and Ps. xvii. 15; but some such anticipation is more generally recognized in Job xix. 25–27; Ps. xlix. 14. 15 and Ps. lxxiii. 17–28. This belief in individual immortality is expressed poetically and obscurely; it is later than the eschatology of the people. It assumes the moral distinction of the righteous and the ungodly, and seeks a solution for the problem of the lack of harmony of present character and condition. Its deepest motive, however, is religious. The soul, once in fellowship with God, cannot even by death be separated from God. The individual hoped that he would live to share the nation's good, and thus the two streams of Old Testament eschatology at last flow together.

Apocryphal and Apocalyptic.—It is in the apocryphal and apocalyptic literature of Judaism that the fullest development of eschatology can be traced. Four words may serve to express the difference of the doctrine of these writings and the teaching of the Old Testament. Eschatology was *universalized* (God was recognized as the creator and moral governor of all the world), *individualized* (God's judgment was directed, not to nations in a future age, but to individuals in a future life), *transcendentalized* (the future age was more and more contrasted with the present, and the transition from the one to the other was not expected as the result of historical movements, but of miraculous divine acts), and *dogmatized* (the attempt was made to systematize in some measure the vague and varied prophetic anticipations). The details of this doctrinal movement may be studied in R. H. Charles, *A Critical History of the Doctrine of the Future Life in Israel, in Judaism, and in Christianity*, 1899.

New Testament.—The eschatology of the New Testament attaches itself not only to that of the Old Testament but also to that of contemporary Judaism, but it avoids the extravagances of the latter. Not at all systematic, it is occasional, practical, poetical, and dominantly evangelical, laying stress on the hope of the righteous rather than the doom of the wicked. The teaching of Jesus centres, according to the Synoptists, in the great idea of the "Kingdom of God," which is already present in the teacher Himself, but also future as regards its completion. In some parables a gradual realization of the kingdom is indicated (Matt. xiii.); in other utterances its consummation is connected with Christ's own return, His Parousia (Matt. xxiv. 3, 37, 39) the time of which, however, is unknown even to Himself (Mark xiii. 32). In this eschatological discourse (Matt. xxiv., xxv.) He speaks of the destruction of Jerusalem and of the end of the world as near, and seemingly as one. This is in accordance with the characteristic of prophecy, which sees in "timeless sequence" events which

are historically separated from one another. While the Return is represented in the Synoptists as an external event, it is conceived in the fourth gospel as an internal experience in the operation of the Spirit on the believer (John xiv. 16–21); nevertheless here also the Parousia in the Synoptic sense is looked for (John xxi. 22; *cf.* 1 John ii. 28). The object of the Second Coming is the execution of judgment by Christ (Matt. xxv. 31), both individual (xxii. 1–14) and universal (xiii. 36–42). This judgment presupposes the resurrection, belief in which was rejected by the Sadducees, but accepted by the Pharisees and the majority of the Jewish people, and confirmed by Christ according to the Fourth Gospel not only as an individual spiritual renovation (John v. 25, 26), but as a universal physical resuscitation (28 and 29), but whether Jesus Himself taught a resurrection of the wicked is doubtful. There is, however, a future punishment for the wicked in Gehenna (Matt. v. 29, 30; x. 28). On the *Intermediate State* Jesus does not speak clearly. But He uses the current terms Hades (Matt. xi. 23; xvi. 18; Luke xvi. 23), Paradise (Luke xxiii. 43) and Gehenna (Matt. xviii. 9) in the accepted meaning without any definite dogmatic import. When He speaks of death as "sleep" (Luke viii. 52; John xi. 11) it is to give men gentler and sweeter thoughts of it, not to inculcate the doctrine of an intermediate state as an unconscious condition. There are words which suggest rather the hope of an immediate entrance of the just into the Father's house and glory (John xiv. 2, 3, xvii. 24). He spoke frequently and distinctly both of the final reward for the righteous and final penalty for the wicked. Degrees of award are recognized (Luke xii. 47, 48). Two sayings are held to point to a terminable penalty (Matt. v. 25, 26, xii. 31, 32), but the one is so figurative and the other so obscure, that we are not warranted in drawing any such definite conclusion from either of them. The finality of destiny seems to be unmistakably expressed (Matt. vii. 23, x. 33, xiii. 30, xxv. 46, xxvi. 24; Mark ix. 43–48, viii. 36; Luke ix. 26; John iii. 16, viii. 21, 24). No second opportunity for deciding the issue of life or death is expressly recognized by Jesus even if such an expectation may be a legitimate inference from what He taught about the Father's love for the lost.

The apostolic eschatology presents resemblance amid difference. Jude (*v.* 6) as well as 2 Peter (ii. 4), refers to the judgment of the fallen angels. 2 Peter describes the place of their detention as Tartarus, and teaches that Christ's Parousia is to bring the whole present system of things to its conclusion, and the world itself to an end (iii. 10, 13). No certainty has been reached in the interpretation of the passages in 1 Peter iii. 18–22 and iv. 6; *cf.* Acts ii. 31, but they suggest to the Christian mind the expectation that the final destiny of no soul can be fixed until in some way or other, in this life or the next, the opportunity of decision for or against Christ has been given. The phrase "the times of restoration of all things" (iii. 21) is too vague in itself, and is too isolated in its context to warrant the dogmatic teaching of universalism. While John's Apocalypse is distinctly eschatological, the Epistles and the Gospel often give these conceptions an ethical and spiritual import, without, however, excluding the eschatological. Life is present while eternal (1 John v. 12, 13), but it is also future (ii. 25). There is expected a future manifestation of Christ as He is, and what the believer himself will be does not yet appear (iii. 2). The writer speaks of the last hour (ii. 18), the Antichrist that cometh (ii. 22, iv. 3), and the Christian's full reward (2 John *v.* 8) as well as the Parousia (1 John ii. 28). The Apocalypse reproduces much of the current Jewish eschatology. A millennial reign of Christ on earth is interposed between the first resurrection, confined to the saints and especially the martyrs, and the second resurrection for the rest of the dead. A final outburst of Satan's power is followed by his overthrow and the Last Judgment.

Although Paul sometimes describes the Kingdom of God as present (Rom. xiv. 17; 1 Cor. iv. 20; Col. i. 13), it is usually represented as future. The Parousia, if more prominent in his earlier writings, is not altogether absent from his later, although the expectation of personal survival does seem to grow less confident (*cf.* 1 Cor. xv. 51 and Phil. i. 20–24). The doctrines of the Resurrection, the Last Judgment, the Reward of the Righteous and the Punishment of the Wicked are not less distinctly expressed than in the other apostolic writings. Peculiar elements in Paul's eschatology are the doctrines of the Rapture of the Saints (1 Thess. iv. 17) and the Man of Sin (2 Thess. ii. 3–6), but these have affinities elsewhere. It is improbable that there is any reference to Christ's millennial reign in 1 Cor. xv. 22–24 or to purgatory in iii. 12–15, or to the descent into Hades in Rom. x. 7 and Eph. iv. 10. Universal restoration is inferred from 1 Cor. xv. 24–28; Phil. ii. 10–11; Eph. i. 9, 10; Col. i. 20. These passages inspire a hope, but do not sustain a certainty. Paul's shrinking from the disembodied state and longing to be clothed upon at death in 2 Cor. v. 1–8, cannot be regarded as a proof of an *interim* body prior to and preparatory for the resurrection body. Paul links the human resurrection with a universal renovation (Rom. viii. 19–23). His eschatology is not free of obscurities and ambiguities; and in the New Testament eschatology generally we are forced to recognize a mixture of inherited Jewish and original Christian elements (*see* ANTICHRIST).

During the first century of the existence of the Gentile Christian Church, "the hope of the approaching end of the world and the glorious kingdom of Christ" was dominant, although warnings had to be given against doubt and indifference. Redemption was thought of as still future, as the power of the devil had not been broken but rather increased by the First Advent, and the Second Advent was necessary to his complete overthrow. The expectations were often grossly materialistic as is evidenced by Papias's quotation as the words of the Lord of a group of sayings from the Apocalypse of Baruch, setting forth the amazing fruitfulness of the earth in the Messianic time.

The Gnostics and Montanism.—The Gnostics rejected this eschatology as in their view the enlightened spirit already possessed immortality. Marcion expected that the Church would be assailed by Antichrist; a visible return of Christ he did not teach, but he recognized that human history would issue in a separation of the good from the bad. Montanism sought to form a new Christian commonwealth which, separated from the world, should prepare itself for the descent of the Jerusalem from above, and its establishment in the spot which by the direction of the Spirit had been chosen in Phrygia. While Irenaeus held fast the traditional eschatological beliefs, yet his conception of the Christian salvation as a deification of man tended to weaken their hold on Christian thought. The Alogi in the 2nd century rejected the Apocalypse on account of its chiliasm, its teaching of a visible reign of Christ on earth for a thousand years. Montanism also brought these apocalyptic expectations into discredit in orthodox ecclesiastical circles.

The Fathers.—The Alexandrine theology strengthened this movement against chiliasm. Clement of Alexandria and Origen both developed peculiar views of their own which did not find general acceptance. In the 5th century there were rejected as heretical (1) "the doctrine of universalism, and the possibility of the redemption of the devil; (2) the doctrine of the complete annihilation of evil; (3) the conception of the penalties of hell as tortures of conscience; (4) the spiritualizing version of the resurrection of the body; (5) the idea of the continued creation of new worlds" (A. Harnack, *History of Dogma,* iii. p. 186).

A doctrine of the most perfect identity between the resurrection body and the material body soon established itself as alone orthodox. Augustine held fast to eternal punishment, but allowed the possibility of mitigations. Some believers, he taught, may pass through purgatorial fires; and this middle class may be helped by the sacraments and the alms of the living. This doctrine was sanctioned and developed by Gregory the Great. This view was inferred indirectly from Matt. xii. 31, and directly from 1 Cor. iii. 12–15. Afterwards purgatory took more and more the place of hell, and was subject to the control of the church. As regards the saints, different degrees of blessedness were recognized; they were supposed to wait in Hades for the return of Christ, but gradually the belief gained ground, especially in regard to the martyrs, that their souls at once entered Paradise. The primitive Christian eschatology was preserved in the West as

it was not in the East, and in times of exceptional distress the expectation of Antichrist emerged again and again. In the middle ages there was an extravagance of speculation on this subject, which may be seen in the last division of Aquinas's *Summa Theologiae.*

Protestant Theology.—While rejecting purgatory, Protestantism took over this eschatology. Souls passed at once to heaven or to hell; a doctrine even less adequate to the complex quality of human life. Luther himself looked for the passing away of the present evil world. Socinianism taught a new spiritual body, an intermediate state in which the soul is near non-existence, an annihilation of the wicked, as immortality is the gift of God. Swedenborg discards a physical resurrection, as at death the eyes of men are opened to the spiritual world in which we exist now, and they continue to live essentially as they lived here, until by their affinities they are drawn to heaven or hell. The doctrine of *eternal punishment* has been opposed on many grounds, such as the disproportion between the offence and the penalty, the moral and religious immaturity of the majority of men at death, the diminution of the happiness of heaven involved in the knowledge of the endless suffering of others (Schleiermacher), the defeat of the divine purpose of righteousness and grace that the continued antagonism of any of God's creatures would imply, the dissatisfaction which God as Father must feel until His whole family is restored. The contention should not be based on the meaning of the word "eternal" but on such broader considerations as have been indicated above. The doctrine of *conditional* immortality taught by Socinianism was accepted by Archbishop Whately, and has been most persistently advocated by Edward White, who "maintains that immortality is a truth, not of reason, but of revelation, a gift of God" bestowed only on believers in Christ; but he admits a continued probation after death for such as have not hardened their hearts by a rejection of Christ. This view is from the standpoint of science maintained by J. Y. Simpson in his book, *Man and the Attainment of Immortality,* 1922. The doctrine of *universal restoration* was maintained by Thomas Erskine of Linlathen on the ground of the Fatherhood of God, and Archdeacon Wilson anticipates such discipline after death as will restore all souls to God. The attitude of theologians generally regarding individual destiny is well expressed by Dr. James Orr, "The conclusion I arrive at is that we have not the elements of a complete solution, and we ought not to attempt it. What visions beyond there may be, what larger hopes, what ultimate harmonies, if such there are in store, will come in God's good time; it is not for us to anticipate them, or lift the veil where God has left it down" (*The Christian View of God and the World,* 1893, p. 397).

Recent Theological Thought.—Although in recent theological thought attention has been mainly directed to individual destiny, yet the other elements of Christian eschatology must not be altogether passed over. History has offered the authoritative commentary on the prophecy of the Parousia of Christ. The presence and power of His Spirit, the spread of His Gospel, the progress of His kingdom have been as much a fulfilment of the eschatological teaching of the New Testament as His life and work on earth were a fulfilment of Messianic prophecy, for fulfilment always transcends prophecy. Even if the common beliefs of the apostolic age have not modified the evangelists' reports of Jesus' teaching, it must be remembered that He used the common prophetic phraseology, the literal fulfilment of which is not to be looked for. Some parables (the leaven, the mustard seed) suggest a gradual progressive realization of His kingdom. The Fourth Gospel interprets both judgment and resurrection spiritually. Accordingly the general resurrection and the last judgment may be regarded as the temporal and local forms of thought to express the universal permanent truths that life survives death in the completeness of its necessary organs and essential functions, and that the character of that continued life is determined by personal choice of submission or antagonism to God's purpose of grace in Christ, the perfect realization of which is the Christian's hope for himself, mankind and the world.

Bibliography.—In addition to the works referred to above the following will be found useful: S. D. Salmond, *The Christian Doctrine of Immortality* (4th ed., 1901); L. N. Dahle, *Life after Death and the Future of the Kingdom of God* (Eng. tr. by J. Beveridge, 1895); J. A. Beet, *The Last Things* (new ed., 1905); W. G. T. Shedd, *Doctrine of Endless Punishment* (New York, 1886); F. W. Farrar, *The Eternal Hope* (1892); E. Petavel, *The Problem of Immortality* (Eng. tr. by F. A. Freer, 1892); E. White, *Life in Christ* (3rd ed., 1878); Macintyre, *The Other Side of Death* (1922); also the relevant sections in books on biblical and systematic theology. *See* also Immortality.

(A. E. G.)

ESCHEAT, in English law, the reversion of lands to the next lord on the failure of heirs of the tenant. This rule is explained by the conception of a freehold estate as an interest in lands held by the freeholder from some lord, the king being lord paramount. (*See* Estate.) As there are now but a very few freehold estates traceable to any mesne or intermediate lord, escheats, when they do occur, fall to the king as lord paramount. Besides escheat for defect of heirs, there was formerly also escheat *propter delictum tenentis,* or by the corruption of the blood of the tenant through attainder consequent on conviction and sentence for the offence of treason or felony. The real estate, therefore, escheated to the next heir, subject to the superior right of the Crown to the forfeiture of the lands—in the case of treason for ever, in the case of felony for a year and a day. All this was abolished by the Felony Act, 1870, which provided for the appointment of an administrator to the property of the convict. Escheat was also an incident of copyhold tenure. Trust estates were not subject to escheat until the Intestates' Estates Act, 1884. (*See* Eminent Domain.) In most of the British colonies escheat has been abolished, and in England this was effected by the Law of Property Act, 1922 (Copyholds), and the Administration of Estates Act, 1925.

In the United States, escheat, in the old English sense, existed in a few of the colonies before the Revolution; it has existed since only so far as regulated by statute. It now means the death of an owner of an estate intestate, that is, without a will or heirs at law, in which case it becomes the property of the state. Public administrators have been named in certain states to take charge of such estates and sell them for the benefit of the state.

ESCHENBURG, JOHANN JOACHIM (1743–1820), German critic and literary historian, was born at Hamburg on Dec. 7, 1743. He studied at Leipzig and Göttingen, and became professor and then director at the Collegium Carolinum in Brunswick. He published a series of German translations of the principal English writers on aesthetics, such as J. Brown, D. Webb, Charles Burney, Joseph Priestley and R. Hurd; and Germany owes also to him the first complete translation (in prose) of Shakespeare's plays (*William Shakespear's Schauspiele,* 13 vols., Zürich, 1775–82). This is virtually a revised edition of the incomplete translation published by Wieland between 1762 and 1766. Eschenburg died at Brunswick on Feb. 29, 1820.

ESCHENMAYER, ADAM KARL AUGUST VON (1768–1852), German philosopher and physicist, was born at Neuenburg, Württemberg, in July 1768. He took his M.D. at Tübingen, and practised at Sulz, and then at Kirchheim. In 1811 he became professor of philosophy and medicine at Tübingen and in 1818 professor of practical philosophy, but in 1836 he retired to Kirchheim, where he devoted himself to philosophical studies. Eschenmayer's views resemble those of Schelling, except in regard to the knowledge of the absolute. He believed that philosophy must be supplemented by "non-philosophy," a kind of mystical illumination by which we arrive at God, the absolute unity, and see Him as the originator of the finite world with its opposing factors. Eschenmayer's mystical tendency led to an interest in the phenomena of animal magnetism. He became a believer in demoniacal and spiritual possession; and his later writings are impregnated with the lower supernaturalism.

His principal works are—*Die Philosophie in ihrem Übergange zur Nichtphilosophie* (1803); *Versuch die scheinbare Magie des thierischen Magnetismus aus physiol. und psychischen Gesetzen zu erklären* (1816); *System der Moralphilosophie* (1818); *Psychologie in drei Theilen, als empirische, reine, angewandte* (1817); *Religionsphilosophie* (3 vols., 1818–24); *Grundriss der Naturphilosophie* (1832); *Die Hegel'sche Religions philosophie verglichen mit dem christl. Princip* (1834); *Der Ischariotismus un-*

serer Tage (1835) (against Strauss's *Life of Jesus*); *Konflikt zwischen Himmel und Hölle* (1837); *Grundzüge der christl. Philosophie* (1840); and *Betrachtungen über den physischen Weltbau* (1852).

ESCHSCHOLTZ, JOHANN FRIEDRICH (1793–1831), Russian traveller and naturalist, was born in Nov. 1793, in Dorpat, where he died in May 1831. He was naturalist and physician to Otto von Kotzebue's exploring expedition during 1815–18, and then became professor of anatomy (1819) and director of the zoological museum in Dorpat. He published the *System der Akalephen* (1829), and the *Zoologischer Atlas* (1829–33). The botanical genus *Eschscholtzia,* which comprises the California poppies, was named by Chamisso in his honour.

ESCHWEGE, a town of Germany, in the Prussian province of Hesse-Nassau, on the Werra, 28 m. S.E. of Cassel. Pop. (1925) 12,748. In the 13th and 14th centuries it belonged alternately to Thuringia and Hesse, but passed definitely to the latter at the beginning of the 15th century. It consists of the old town on the left, the new town on the right bank of the Werra, and Brückenhausen on a small island connected with the old and new towns by bridges. Its chief industries are leather-making, metal-founding, yarn-spinning, cotton- and wool-weaving, the manufacture of cigars, machines, barrels, cork and soap-boiling. It has two ancient buildings, the Nikolai-turm, built in 1455, and the old castle.

ESCHWEILER, a town of Germany, in the Prussian Rhine province, on the Inde, and the Cologne-Herbesthal railway, about 8 m. E.N.E. from Aix-la-Chapelle. Pop. (1925) 26,023. The manufacture of iron, steel and zinc goods is carried on; other industries include tanning, distilling and brewing. In the neighbourhood there are valuable coal mines.

See Koch, *Geschichte der Stadt Eschweiler* (Frankfort, 1890).

ESCOBAR Y MENDOZA, ANTONIO (1589–1669), Spanish churchman, was born at Valladolid, and at the age of fifteen became a Jesuit. He soon became a famous preacher, and his facility was so great that for fifty years he preached daily. His best known works are *Summula casuum conscientiae* (1627); *Liber theologiae moralis* (1644), and *Universae theologiae moralis problemata* (1652–66). The first contains the famous maxim that purity of intention may be a justification of actions which are contrary to the moral code and to human laws. Its doctrines were criticized in the fifth and sixth of Pascal's *Provincial Letters* and were ridiculed in witty verses by Molière, Boileau and La Fontaine. Escobar also wrote Biblical commentaries and Latin verses in praise of Ignatius Loyola.(1613) and of the Virgin (1618). He died at Valladolid on July 4, 1669.

ESCOIQUIZ, JUAN (1762–1820), Spanish ecclesiastic, politician and writer, was born in Navarre in 1762. He entered the church, was a prebendary of Saragossa, and acted as tutor to Prince Ferdinand (Ferdinand VII.). He was a busy and pushing member of the literary clique which looked up to Godoy as its patron. But as Ferdinand grew up, and after his marriage with a Neapolitan princess, Escoiquiz became the centre of a court opposition to Godoy and to his policy of alliance with France. He was exiled from the court, but, nevertheless, contrived to take part in the conspiracy of the Escorial in October 1807. He was imprisoned and sent for trial with other conspirators. But as they had appealed to Napoleon, who would not suffer his name to be mentioned, the government had to allow the matter to be hushed up, and the prisoners were acquitted. After the outbreak at Aranjuez (March 17, 1808), in which he had a share, he became one of the most trusted advisers of Ferdinand. The new king's decision to go to meet Napoleon at Bayonne was largely inspired by him. His *Idea sencilla de las razones que motivaron el viaje del Rey Fernando VII. a Bayona* (1814) is a valuable historical document, and contains a singularly vivid account of an interview with Napoleon. When the Spanish royal family was imprisoned by Napoleon, Escoiquiz remained with Ferdinand at Valençay. When Ferdinand was released in 1814 he came back to Madrid, but after a very brief period of office in 1815 he was sent as a prisoner to Murcia. Though he was afterwards recalled, he was again exiled to Ronda, where he died on Nov. 27, 1820.

ESCOMBE, HARRY (1838–1899), South African statesman, a member of a Somersetshire family, was born at Notting Hill, London, on July 25, 1838, and educated at St. Paul's school. He emigrated, in 1859, to the Cape. He practised as an attorney in Natal, and in 1872 was elected to the legislative council. In 1880 he secured the appointment of a harbour board for Natal, and was himself made chairman. The transformation of the port of Durban into a harbour available for ocean liners was due to his energy. In 1888–89 he defended Dinizulu and other Zulu chiefs against a charge of high treason. On the grant of responsible government in 1893, he served as attorney general under Sir J. Robinson in the first ministry, and was prime minister of Natal in 1897 for a few months. In Oct. 1899 he prepared measures of defence against the invasion by the Boers. He died on Dec. 27, 1899.

The *Speeches of the late Right Hon. Harry Escombe* (Maritzburg, 1903), ed. J. T. Henderson, contains brief biographical notes by Sir John Robinson and the editor.

ESCORIAL or **ESCURIAL,** in Spain, is one of the most remarkable buildings in Europe, comprising a convent, a church, a palace and a mausoleum. It is situated in wild and barren country 3,432 ft. above the sea, on the south-western slopes of the Sierra de Guadarrama, within the borders of the province of Madrid and the kingdom of New Castile. By the Madrid-Avila railway it is 31 m. N.W. of Madrid.

According to the usual tradition, the Escorial owes its existence to a vow made by Philip II. of Spain (1556–98), shortly after the battle of St. Quentin, in which his forces succeeded in routing the army of France. The day of the victory (Aug. 10, 1557) was sacred to St. Laurence, and the building was dedicated to that saint, and received the title of *El real monasterio de San Lorenzo del Escorial.* The last distinctive epithet was derived from the little hamlet in the vicinity which furnished shelter, not only to the workmen, but to the monks of St. Jerome, who were afterwards to be in possession of the monastery; and the hamlet is generally supposed to derive its name from the *scoriae* or dross of certain old iron mines. The work was entrusted to Juan Bautista de Toledo, and the first stone was laid in April 1563. On the death of Toledo in 1567 a worthy successor was found in Juan Herrera. On Sept. 13, 1584, the last stone of the masonry was laid.

The ground plan of the building is estimated to occupy an area of 396,782 sq.ft. There are seven towers, 15 gateways and, according to Los Santos, no fewer than 12,000 windows and doors. The church is the finest portion of the whole Escorial and ranks as one of the great Renaissance churches of Europe. It is about 340 ft. from east to west by 200 from north to south, and thus occupies an area of about 70,000 sq.ft. The dome is 60 ft. in diameter, and its height at the centre is about 320 ft. Directly under the altar is situated the pantheon or royal mausoleum, a richly decorated octagonal chamber. The library, situated above the principal portico, was at one time one of the richest in Europe, comprising the king's own collection, the spoils of the emperor of Morocco, Muley Zidan (1603–1628) and various contributions from convents, churches, cities and private libraries. Among its curiosities still extant are two New Testament Codices of the 10th century and two of the 11th; various works by Alphonso the Wise (1252–84), a Virgil of the 14th century and a Koran of the 15th.

Of the artistic treasures with which the Escorial was gradually enriched, it is sufficient to mention the frescoes of Pellegrino Tibaldi, Luis de Carbajal, Bartolommeo Carducci or Carducho and Luca Giordano, the crucifix of Cellini and the pictures of Titian, Tintoretto, El Greco and Velasquez. After the conflagration of 1671, only the church, a part of the palace, and two towers escaped uninjured. In 1808 the whole building was exposed to the ravages of the French soldiers. In 1872, the college and seminary, a part of the palace and the upper library were devastated by fire; but the damage was subsequently repaired. In 1885 the conventual buildings were occupied by Augustinian monks.

fundacion del Escorial y su fabrica, in the *Coleccion de documentos inéditos para la historia de España,* vol. vii.; J. de Herrera, *Sumario y breve declaracion de los diseños y estampas de la fab. de S. Lorencio el Real del Escurial* (Madrid, 1589); José de Sigüenza, *Historia de la orden de San Geronimo,* etc. (Madrid, 1595–1605).

ESCOVEDO, JUAN DE (d. 1578), Spanish politician, secretary of Don John of Austria, began life in the household of Ruy Gomez de Silva, prince of Eboli. When Don John of Austria, after the battle of Lepanto in 1571, began to launch on a policy of self-seeking adventure, Escovedo was appointed as his secretary with the intention that he should act as a check on these follies. He began to disobey orders from Madrid and became entangled in intrigues to manage or even to coerce the king. In July 1577, and contrary to the king's orders, he came to Spain from Flanders, where Don John was then governor. The king gave orders to Antonio Perez that he was to be put out of the way. After two clumsy attempts had been made to poison him at Perez's table, he was killed by bravos on the night of Easter Monday, March 31, 1578.

See Gaspar Muro, *La Princesse d'Eboli* (Paris, 1878); and W. H. Prescott, *Reign of Philip II.* (1855–59).

ESCROW, a written agreement entered into by three parties, the obligor, the obligee, and the depositary, for the transfer or conveyance of certain property. The sealed agreement of the obligor (generally accompanied by the deed, bond or chattel to be conveyed) made contingent upon some future happening, or upon the performance of some act by the obligee, is delivered to the depositary and held by him pending the occurrence of that event or the performance of the required act by the obligee. When the event has taken place or the obligee has performed the specified act, the depositary delivers to him the agreement and the deposit which he has held, and the transaction is complete. The depositary or custodian is allowed no discretion but must follow strictly the terms of the agreement as it concerns the other two parties.

ESCUDO, the monetary unit of Portugal. Prior to the revolution, the monetary unit was the milreis, equivalent nominally to 108 cents, but as Portugal has never adopted the full gold standard, the milreis fluctuated widely in value.

The result of the revolution was to change the name of the unit from "milreis" to "escudo," and during and since the World War, it has lost most of its value. In 1920 it was worth 10.49 cents, and by 1924 it had fallen to 2.8 cents. By the end of 1927 it had improved to about five cents in value.

Notes of the Portuguese Bank are in circulation. In 1913, 87,000,000 escudos were outstanding, but by the end of 1926 the volume had risen to 1,836 millions. Against these the bank held reserves in gold and "foreign assets" amounting to 58 millions of escudos. These are presumably valued at the par of exchange of 108 cents, and if they were revalued at the rate then current of five cents, they would stand at 1,250 millions. In reality, therefore, the note issue has ample backing, but a revaluation of the escudo is dependent upon the maintenance of stable financial and political conditions.

ESCUINTLA, a city of Guatemala, Central America, 47m. W. of Guatemala City on the main line of the International railways of Central America. Pop. about 13,000. Escuintla is a commercial centre of some importance, as it lies at the western foot of the cordillera, and has tributary to it a considerable area of sugar, cacao and coffee country. Hot springs located near Escuintla are frequented during the season, from February to April.

ESCUTCHEON, a heraldic term for a shield with armorial bearings displayed (*see* HERALDRY). The word is also applied to the ornamented plates from the centre of which door-rings, knockers, etc., are suspended, or which protect the wood of the key-hole from the wear of the key.

ESENIN, SERGIUS (1895–1925), Russian poet, was born Oct. 4, 1895, in Constantinovo, since his death officially renamed Esenino, in the Ryazan province. A peasant by birth, he lived in his native village until he was 17 when he moved to Moscow. His first poems (1915) met with immediate success. In 1919 he founded the Imagist group. Esenin travelled in Persia and also visited America and France. He was married first to the American dancer, Isadora Duncan, from whom he soon parted, and secondly to a grand-daughter of Count Leo Tolstoy. He died by his own hand on Dec. 28, 1925. Although he was a staunch supporter of the Soviets, his meditative and purely lyrical talent was tragically out of touch with the matter-of-fact post-Revolutionary Russia.

Esenin has been considered the finest Russian poet of his generation and second only to Blok. His poetry reflects the mysticism of the old Russian peasantry with its ikons and its folklore, as in "Radunitza" (Day of the Dead), "Goluben" (Blueness); in "Inonia" he depicts a religious Utopia and proclaims the advent of a "peasant Christ." All his poems reflect the same love for peasant Russia, its fields, thatched cottages, its trees and animals. He called himself "the last peasant poet" and deplored the invasion of the land by the town—"the iron guest." His town and tavern poems ("Moscow of the Taverns," "The Confessions of a Hooligan," etc.) describing the evil victory of the town and its allurements, are of a tragic and captivating sincerity. His poetic style is highly imaginative and his simple, transparent verse follows the classic Pushkin tradition.

See English translations in *The Chapbook,* No. 31 (Nov. 1922) and *The Bermondsey Book* (March 1926); articles by Trotsky, *Pravda* No. 15 (1926) and Z. Vengerova, *The Bermondsey Book* (March 1926).

ESHER, REGINALD BALIOL BRETT, 2ND VISCOUNT (1852–), British politician and writer, eldest son of the 1st Viscount Esher, was born in London, June 30, 1852, and educated at Eton and Trinity college, Cambridge. He entered politics, becoming private secretary to the Marquess of Hartington in 1878, and from 1880 to 1885 was Liberal member for Penryn and Falmouth. From 1895 to 1902 he was secretary to the Office of Works. He succeeded his father in 1899 and in 1901 was appointed deputy constable and lieutenant-governor of Windsor Castle. In 1902 he was appointed one of the commissioners who enquired into the conduct of the South African War. In 1904 he was chairman of the War Office reconstitution committee, and in 1905 became a permanent member of the committee of imperial defence. He was chairman of the Territorial Force Association of the county of London 1909–13, and president, 1912–21. Lord Esher was selected by King Edward VII. as one of the editors of the *Letters of Queen Victoria,* which appeared in 1907, and he produced *The Girlhood of Queen Victoria* (1912). His other works include *The Influence of King Edward* (1915), *The Tragedy of Kitchener* (1921), *Ionicus* (1923) and *Cloud-capt Towers* (1927).

ESHER, WILLIAM BALIOL BRETT, 1ST VISCOUNT (1817–1899), English lawyer and master of the rolls, was born at Chelsea, London, on Aug. 13, 1817. He was educated at Westminster and at Caius college, Cambridge. Called to the bar in 1840, he went the northern circuit, and became a Q.C. in 1861. On the death of Richard Cobden he unsuccessfully contested Rochdale as a Conservative, but in 1866 was returned for Helston. Brett rapidly made his mark in the House, and in 1868 he was appointed solicitor-general. On behalf of the crown he prosecuted the Fenians charged with having caused the Clerkenwell explosion. In parliament he took a leading part in the promotion of bills connected with the administration of law and justice. He was (August 1868) appointed a justice in the court of common pleas. Some of his sentences in this capacity excited much criticism, notably so in the case of the gas stokers' strike, when he sentenced the defendants to imprisonment for twelve months, with hard labour, which was afterwards reduced by the home secretary to four months. On the reconstitution of the court of appeal in 1876, Brett was elevated to the rank of a lord justice. After holding this position for seven years, he succeeded Sir George Jessel as master of the rolls in 1883. In 1885 he was raised to the House of Lords as Baron Esher. The Solicitors Act of 1888, which increased the powers of the Incorporated Law Society, owed much to his influence. He retired from the bench at the close of 1897, and a viscounty was conferred upon him on his retirement. He died in London on May 24, 1899.

ESHER, a township in the Chertsey parliamentary division of Surrey, England, on the Portsmouth road, 14½ m. S.W. of London

on the Southern railway. It is pleasantly situated on rising ground above the river Mole, 3 m. from its junction with the Thames. Of the ancient mansion of Esher place, founded by William of Waynflete, bishop of Winchester (*c.* 1450), in which Cardinal Wolsey resided for some weeks in 1529, the gatehouse remains. The modern mansion was erected in 1803. To the south is Claremont, built by the great Lord Clive (1769) on the site of a mansion of Sir John Vanbrugh. In 1816 it was presented to Princess Charlotte, on her marriage to Prince Leopold, afterwards king of the Belgians. She died here in 1817, and on the death of her husband in 1865 the property reverted to the Crown. Louis Philippe, ex-king of the French, resided here from 1848 until his death in 1850, and later the duke of Albany. In 1882 Claremont became the private property of Queen Victoria. Christ Church, Esher, contains some interesting memorials. The township lies within the urban district of Esher and The Dittons, which includes the favourite riverside resort of Thames Ditton and the Sandown Park racecourse. The whole district is largely residential and the ancient commons, including Ditton Marsh and Littleworth, are of wide extent. Pop. of urban district (1921) 14,309.

ESKER, a name for long and often winding ridges of gravel and sand in regions of former glaciation, notably in Ireland, Sweden (where they are called åsar), and in the state of Maine, U.S.A. Their origin has given rise to much controversy, but they are generally considered to represent the material formerly filling the channels of streams under, within, or even upon the ice. This material is left behind as the ice melts. (*See* also GLACIAL PERIOD.) (R. H. RA.)

ESKILSTUNA, a town of Sweden in the district (*län*) of Södermanland on the Hjelmar river, which unites lakes Hjelmar and Mälar, 65 m. W. of Stockholm by rail. Pop. (1928), 30,622. It is mentioned in the 13th century, and is said to derive its name from Eskil, an English missionary martyred on the spot. It rose into importance in the reign of Charles X., who bestowed on it considerable privileges, and gave the first impulse to its manufacturing activity. It is the chief seat in Sweden of the iron and steel industries, its cutlery being especially noted, while damascened work is a specialty. There is a technical school for metal industries. There are, in the town or its neighbourhood, great engineering works.

ESKIMO LANGUAGE. This language is spoken with only a few varieties of dialect from Greenland along the arctic coasts of Canada to the Bering straits (Eskimo settlements on the Asiatic side) and along the southern coasts of Alaska, on the south coast near to Mt. Elias. On the Aleutian islands Eskimo influence is found. The Chukchee on the easternmost peninsula of Siberia are in touch with the Eskimo, and have some features in common. The Eskimo dialects have been regarded as akin to the Ural-Altaic family.

Phonetics. System of consonants of the central west Greenland dialects

	lip	point of tongue (blade)	back	uvula	
tenues (stops)	p	t	k	ᴋ	voiceless
fricatives (open)	ʋ	j l	g	ʀ	voiced
aspirates	ɸ	ꞅ s λ	χ	ꞅ	voiceless
nasals	m	n	ŋ	ɴ	voiced

The consonants have a four-fold division and an abundance of fricatives and uvulars, the latter articulated in the inmost parts of the mouth. Before a uvular consonant the vowels *e*, *o*, and *a* become *uvularized* (retracted towards the uvula), *e.g.*, in *er*ᴋ*e*ᴋ, a nit; *orsso*ᴋ, blubber; ᴋ*a*ᴋᴋ*a*ᴋ, hill. This gives the speech a guttural sound. Otherwise their speech is melodious and expressive. There is no system of pitch in the words to differentiate the meanings. The stress accent is dependent on the weight of the syllable. Since both consonants and vowels occur, now short, now long, and the meaning of the word is strictly dependent on these differences, the rhythm of speech is very irregular, somewhat like that of a drum, especially noticeable in recitation or lofty style.

In the early literary language the peculiar sounds and accents were incompletely reflected. The orthography was firstly coined by Hans Egede and his son Paul in their Greenland translations of the Bible and the linguistic pioneer works of Paul Egede (*Dictionarum*, 1750, *Grammatica Groenl.*, 1760). In modern Greenland orthography, reformed by the missionary Samuel Kleinschmidt (*Grammatik der grönländischen Sprache mit theilweisem Einschluss des Labrador Dialects*, Berlin, 1851), the four uvulars are rendered as ᴋ, r, rr, rng, and the aspirated fricatives as vf (gf), ss (gss), dl (tdl), gg, rr. g (*iga*, kettle) is pronounced as in North German *Regen*, gg as ch in *ich*, j always as y in *yes;* in North and East Greenland dialects g is replaced by ng (*iŋa*, kettle), and dl in East Greenl. by t.

The main Greenland dialects centre around Godthaab in West Greenland and Angmagssalik (pronounced Ammassalik) on the east coast. In the Central Eskimo dialects west of Davis strait the Greenl. s and ss (*issé*, eye; *isse*, frost) correspond to j and tj (Labrador *ijé; itje*), and west of Hudson Bay the Greenl. initial s (*siko*, ice) is replaced by h (*hiko*). The dialects of western Alaska differ fundamentally from those of Greenland.

Grammatical Structure.—The language is polysynthetic. The grammar is extremely rich in flexional forms, the conjugation of a common verb being served by about 350 suffixes, equivalent to personal pronouns and verb endings. For the declension of a noun there are 150 suffixes (for dual and plural, local cases, and possessive flexion). The demonstrative pronouns have a separate flexion. The derivative endings effective in the vocabulary and the construction of sentences or sentence-like words amount to at least 250. Notwithstanding all these constructive peculiarities, the grammatical and synthetic system is remarkably concise and, in its own way, logical.

The plural ending is *t* (or *it*), both in nouns and verbs. Besides, there is a dual in k. There is no article and no gender, nor any separate auxiliaries or copulas except such as are expressed by means of suffixes. The possessive relation is nearly always emphasized, if the nature of the noun involves possession. There is a large system of possessive suffixes in singular, dual, and plural, which take the place of possessive pronouns; and the same endings appear in part also in the flexion of the verb.

Possessive suffixes of nouns recognizable in verb endings:

igdlu-a his hut (*igdlo*)	ᴋ*ajâ* his kayak
igdlu-ga my hut	ᴋ*aja-ra* my kayak
igdlo-rse your hut	ᴋ*aja-rse* your kayak
igdlo hut; *igdlut* huts	ᴋ*aja*ᴋ kayak

takuvâ (*-aa*) he saw it
takuva-ra I saw it
takuva-rse you saw it
*takuvo*ᴋ he sees (saw)

The possessive flexion embraces a double set of suffixes, transitive and intransitive, agreeing with the fact that the noun has two basal cases of function in the sentence, the Absolutive case ending in k, ᴋ, t, or a vowel, and the Relative in p, the latter also having the function of the genitive. The Absolutive is used if the noun is the subject of an intransitive verb (ᴋ*aja*ᴋ *tikipo*ᴋ, a kayak has arrived), or object of a transitive verb (*kajak takuvara*, I saw a kayak). The Relative has the function of the subject of a transitive verb, *e.g.*, *puissip* ᴋ*aja*ᴋ *takuvâ*, the seal (*puisse*) saw the kayak. There are separate series of possessive suffixes for each of these functions of the noun.

The verb has an indicative and interrogative and a great number of subordinate moods (contemporative participle; causal proposition, etc.). There are four degrees of conjugation and besides a special negative conjugation common to all verbs (*-ngila* does not, *e.g.*, *takûngilara*, I did not see him). The numeral system is quinary, based on 1 to 5, though with special terms of 6, 10, 11 and 16, and it amounts to 21. They count by

means of their fingers and toes, 20 being "a man brought to an end."

Mentality.—The vocabulary is rich in expressions referring to hunting life and animals, technical terms of weapons and utensils in all their details and uses, terms of all sorts of empiric notions, and terms referring to the mind and senses, *e.g.*, special word stems meaning to die from thirst, hunger, cold or longing. A peculiar category of basal stems expresses incapability, *e.g.*, stems meaning not to know, not to be able to, to have no proof, not to regard, etc., whereas the corresponding stems to know, prove, regard, do not exist. "I know" is expressed by "I do not ignore," even "to be good" has no positive stem, but is produced by negation of being bad or evil (*ajorpoK*, is bad—*ajúngilaK*, is good). They have words for stones of many kinds, iron, copper, but none for metal; for the various colours, but not for colour; for numbers, but none for number; for Eskimo (*inuk*, in plur. *inuit*) and for some few neighbouring peoples in Canada, but none for man (humanity).

ESKIMOS. The name Eskimo is said to have come from Indian neighbours to the south, and to signify people who eat their food raw. This name seizes upon one of the striking cultural differences between the Eskimos and at least the most northerly Athabascans of Canada. The Slaveys and Dog-Ribs, for instance, were horrified even at seeing white men eating their ordinary underdone roasts; they would naturally be still more revolted with the Eskimo habit of eating not only underdone meats but also completely raw flesh on occasion.

According to the view of the greater number of leading anthropologists, the Eskimos are merely one kind of North American Indian, both in blood and language. A few authorities state that they are lighter in complexion than most other Indians, but the majority opinion holds them to be average North American natives in eyes, complexion and hair. In head-form different groups range between average cephalic indices of 74 and 82. In stature they are not a particularly small people, the men averaging 1,647 mm. in east Greenland, 1,648 mm. around Coronation Gulf, 1,689 mm. at the Mackenzie mouth, and 1,682 mm. on the Noatak River in western Alaska. In the districts of southwest Greenland and Labrador there is so much white blood that neither the original stature of the people nor any other physical characteristic can be determined.

It seems likely that some two thousand years ago, or less, the ancestors of the present Eskimos were forest dwellers north of Lake Superior. Then, apparently, they moved north till they struck the Canadian Arctic coast somewhere between Coronation Gulf and Boothia Peninsula, splitting there into two main streams, one flowing northeast across the islands and then southeast into Greenland, the other west along the north coast of America and around the west and south coasts of Alaska as far as Prince William Sound. A few hundred, apparently in fairly recent times, crossed over to Siberia and occupied the immediate corner around and a little beyond East Cape. The Labrador Eskimos crossed Belle Isle straits and penetrated some distance south into Newfoundland, but it is not clear whether these were forays or permanent settlements.

About half the Canadian arctic islands are either occupied now by Eskimos or visited by them occasionally. Other islands, such as Melville, were occupied some centuries ago, perhaps only for a short period. Prince Patrick Island has not yet been so fully explored that we know whether it ever was occupied, and the same is true of the Ringnes Islands. But Brock, Borden, Lougheed and Meighen Islands were sufficiently examined by the Stefansson Expedition of 1913–18 to make it seem probable that they were never occupied and perhaps never even visited by Eskimos, whether in ancient or modern times.

In 1928 the total Eskimo population was estimated at 30,000. Of this number about half have more or less white blood. Out of nearly 15,000 Eskimos in Greenland, perhaps 10,000 come under this head, and some are practically white. The like is true of southern Labrador, where people classified as Eskimos speak no language but English. There has also been some blood mixture on the west coast of Hudson Bay and in Baffin Island; but from King William Island west to and including Victoria Island there has been no European intermarriage in historic times, and it is one of the disputed questions whether the so-called "Blond" Eskimos of Coronation Gulf and southwest Victoria Island have European blood (in that case derived from the Norse colony which occupied Greenland in the Middle Ages), or whether the few "blond" individuals in this district are pure North American Indians who came by their lighter complexions "naturally." There is an uninhabited stretch of about 200 miles from Coronation Gulf to Cape Bathurst. Thence westward slight recent admixture with Europeans begins, and increases along the south-west Alaskan coast and south to the limit of Eskimo occupation.

ESKIMO FATHER COUNTING TO HIS SON ON HIS FINGERS, FINGER AND TOE ENUMERATION BEING THE ONLY METHOD OF COUNTING KNOWN TO ESKIMOS. THE FIGURE 20 MEANS "A MAN COUNTED TO THE END"

It is difficult to estimate what the population may have been before the white man came. Contagious diseases, introduced by Europeans, notably measles, have wrought great havoc among the Canadian and Alaskan Eskimos. In certain western districts a single epidemic about a quarter of a century ago is known to have killed from 25% to 75% in different places. Judging from Richardson's account, there must have been more than a thousand Eskimos in the Mackenzie delta in 1848, and perhaps twice that number. But in 1906 Stefansson found these represented by less than thirty descendants. Fully half of that reduction appeared to be accounted for by two epidemics within the memory of people who were still living in 1906, and the preceding reduction was doubtless due to epidemics then forgotten, perhaps one or more of the smallpox plagues that have swept aboriginal Canada. Similar reductions in numbers seem likely for all sections except Greenland. Even there epidemics doubtless took toll formerly, but a strict quarantine maintained by the Danes has enabled the population to increase considerably during the last half century. Perhaps 100,000 may be a reasonable minimum estimate for Eskimo numbers before white contact began to injure as well as benefit the natives.

It seems probable that the various epidemics have now killed off most of the susceptibles (except between King William and Victoria islands), leaving only the immunes and the descendants of immunes, so that the Eskimo population generally is probably now at about its lowest numerical ebb. It seems likely, therefore, from all accounts, that the Eskimos are destined to disappear not by actually dying out but by merging into the white population, with whom they readily intermarry. A strong social prejudice against such marriages is found only in large towns, like Nome, Alaska. In places where the Eskimos markedly outnumber the whites there is no such prejudice.

A description of the living habits of the Eskimos at once brief and clear is impossible, for they live under many environments, both natural and social. In southwest Greenland, for instance, they have been in touch with Europeans for nine hundred years. But on the south shore of Dolphin and Union Straits and elsewhere they had never seen Europeans, either so far as we or they know, until the Second Stefansson Expedition in 1910, and there were even small numbers farther east and south who had never met Europeans until the Rasmussen Expedition in 1923. These

same Eskimos had naturally never seen a book, or words either written or printed; but the Eskimos of south-west Greenland have been publishing every year since 1861 an annual in their own language, edited and printed by themselves, exclusively from Eskimo contributors, both writers and artists. Some Eskimos in Greenland live more than 600 miles north of the arctic circle, but others in Labrador live more than 600 miles south of the circle. Many Eskimos have never seen a tree but others visit forested country either occasionally or frequently, and some live perpetually or temporarily in or near a forest. In Hudson Bay they have had the current firearms of Europe in every decade since before the American Revolution, but in Coronation Gulf all of them were still hunting with bows and copper-tipped or stone-tipped arrows in 1910. Some have lived for decades almost entirely on food which they buy with wages, others buy no food even now and live exclusively by hunting or fishing. Some Eskimos depend mainly on seal, some eat that meat rarely, and a few have never tasted it. Whales, even bowhead running towards 80 feet in length, were captured in some districts of Alaska and Canada as far east as Coronation Gulf, and again around Baffin island and other eastern districts. In most other parts the larger whales were not captured, and consequently not eaten, except when they happened to drift ashore dead. The smaller whales, such as the beluga, were more widely hunted. The walrus is important food in certain easterly and westerly districts, but not in the central section from Point Barrow to Hudson Bay. Some Eskimos live mainly by caribou hunting and others have never seen a caribou; some live mainly by fishing while others rarely taste fish.

Even such common statements as "Eskimos live in snow houses" are, in that simple form, more entertaining than instructive, for over half the Eskimos in the world have never seen a snow house, and only about one-quarter are in the habit of using them as the common dwellings of winter. Snow houses are wholly absent from Alaska. In the Mackenzie delta they were used only in emergencies. From there eastward to the Atlantic, however, they are the usual winter dwelling except in parts of Labrador. Of nearly 15,000 Eskimos in Greenland to-day, less than 500 have ever seen a snow house. The only Greenlandic snow-house users are the small group around Cape York, and even they more commonly dwell in houses of earth raftered with slabs of stone or with the bones of large animals.

The Eskimos speak one language from easternmost Greenland to farthest Alaska as do also a few hundred people in Siberia on the other side of Bering Straits. It is of the type called polysynthetic. In order to get along reasonably well an Eskimo must have at the tip of his tongue a vocabulary of more than 10,000 words, much larger than the active vocabulary of an average business man who speaks English. Moreover these Eskimo words are far more highly inflected than those of any of the well-known European languages, for a single noun can be spoken or written in several hundred different forms, each having a precise meaning different from that of any other. The forms of the verbs are even more numerous. The Eskimo language is, therefore, one of the most difficult in the world to learn, with the result that almost no traders or explorers have even tried to learn it. Consequently there has grown up, in intercourse between Eskimos and whites, a jargon similar to the pidgin English used in China, with a vocabulary of from 300 to 600 uninflected words, most of them derived from Eskimo but some derived from English, Danish, Spanish, Hawaiian and other languages. It is this jargon which is usually referred to by travellers as "the Eskimo language." (*See* ESKIMO LANGUAGE.)

Roughly speaking, the Eskimos are, in social organization, communistic anarchists, with the modification that usually raw materials are common property but made articles are privately owned. In the Mackenzie district, for instance (before European influence became strong), a pile of fish caught by a man belonged to him only in a modified sense. Large animals were divided among the people present at the kill, but smaller animals would be taken home by the one who caught them. However, when these were cut up the hunter's wife would either give pieces of raw meat to all who wanted them, or only to families that had none of their own. In some cases she would send away no meat but would shout an invitation to all within hearing to come and share the meal after she had cooked it. Really personal articles, such as a woman's sewing gear, could be sold by her without asking her husband's consent, although she usually asked his advice. He could similarly sell his private hunting gear, but seldom did so without previous discussion with his wife. A thing of recognized common property, such as a dog, could never be sold "legally" except by both man and wife. If it did happen that a husband sold a dog without consulting his wife, the community thought it reprehensible. A house belonged to the family that built it as long as they occupied it, and, if they wanted to retain ownership when they moved away, they could do so, but only for a short time by leaving a substantial part of their property behind. This was seldom done, however, for when a man moved away he usually intended to be gone at least a year and in that case was perfectly willing that anyone else should move in. The first comer did move in, and if by some accident the builder's family returned they would no more think of ousting the new occupant than we would think of driving away a camper who had pitched his tent on public land where our tent had stood the week before.

A statement about the Eskimo religion can scarcely be brief and clear without being misleading. It is not far wrong, however, to say that the idea of worship as Christians understand it is rudimentary or absent. In the Mackenzie district, for instance, Stefansson found no trace of any idea like that of a god or a goddess, although it has been found by Boas, Rasmussen and others farther east, possibly because it is 900 years since the Greenland Eskimos first came in contact with the Christian Norse colony. There have been several centuries of Christian contact, too, around Davis Straits and Hudson Bay, whereas the same contact is less than a century old at the Mackenzie mouth, and really less than half that, so far as effective cultural relations are concerned.

Judging from the Mackenzie view, the Eskimos formerly thought of every stick and stone as well as every cloud and beast and bird as having a life or a soul. To their mind nothing in Nature ever happens; it is always done by or through some spirit. These are not worshipped, or influenced by anything like prayer, but are controlled by charms and magic formulae. A spirit, according to that view, is neither good nor bad, but merely does the good or evil bidding of him who controls it. This controller is always some human being, most likely a shaman; but it may be anyone who has a charm or knows a magic formula.

Like more highly civilized people, the Eskimos are, of course, confused in their religious thinking. Different answers and confused answers come from the most thoughtful and best-informed members of the same community. As a general rule the Mackenzie Eskimos do not think that bad weather or a famine is caused by any spirit acting for itself, though it may be caused by a spirit acting for a shaman. But they agree that famines sometimes come without the intervention of a malevolent human being. As nearly as we can express it, they seem to think that these famines come automatically as the result of the breaking of some tabu—not that this breaking offends any spirit but merely that the famine just comes when a tabu has been broken. Such a famine or other unfavourable condition can be changed by discovering who has broken a tabu and getting that person to confess. This confession need not be accompanied by any penitence or effort at restitution. Just as the mere breaking of a tabu brings on trouble so does the mere confession stop it.

There is an almost infinite variety of tabus among the Eskimos. Every act of human life can be subject to tabu. Still the most numerous and complicated are the ones which relate to food. In northern Alaska, for instance, the number of tabus applying to mountain sheep alone is no doubt much greater than the entire number of tabus mentioned in the Bible as applying in one way or another to every variety of food and drink used by the Jews.

Public opinion is the only controlling influence over those Eskimos who have been little influenced by other North American Indians or by whites. The force of this public opinion is to us incomprehensibly strong. It appears unthinkable to an ordinary

Eskimo to go against it. There are no chiefs, soldiers, police or prisons, and there are practically only two punishments; the disapproval of the community, and death. When an individual becomes intolerable there are informal discussions about him that go on for months and perhaps for years. There is such secrecy about these that it is seldom that even a man's own mother tells him about it. In case of eventual unanimity, the theoretically right thing is that the obnoxious person shall be killed by his nearest of kin. This is to prevent blood feud, for the highest duty of revenge lies upon the nearest relative. If the nearest acts as executioner, there is no one to take revenge upon.

In cases where a man is killed before the community arrives at unanimity of opinion there is usually a blood feud. Such feuds end usually by the family that is for the moment one ahead in the retaliation game suddenly moving bag and baggage to a distant community. Even so, there have been instances of revivals of feuds after as much as twenty years. An exceptional making-up of all blood feuds occurred in the Mackenzie district following the dreadful measles epidemic of 1900 which destroyed most of the community. The survivors agreed that now they were so few they must bury all differences along with their dead.

Monogamy is the common relation of the Eskimos, but polygamy and polyandry are either of them socially permissible, and both occur. In the Mackenzie district a second wife is usually taken by a man on the suggestion of the first wife who points out either that her health is not good enough or that the family and household are now too large for her to manage without assistance. The husband, however, selects the second wife. She nevertheless usually gets along very well with the chief wife, being in some measure a form of favoured servant.

There are no other servants in an Eskimo household, excepting that anyone who chooses to adhere to the family and who is admitted into it naturally does his or her share of the work. Voluntary adherents who are blind, crippled or ill, are taken in as readily as those who are well (at least that is the theory) and are expected to do no work, or only what their infirmity permits. The head of a family is proud of the number of voluntary adherents that gather to him, for it is a sign that he is looked upon as a resourceful man and a good provider. He is even more proud of the dependents who cannot work, for their number shows that he has a superabundance of resources, since he can care for them. The leading man of the Mackenzie community in 1906, for instance, had a family of twenty-seven, nineteen of whom were voluntary adherents, three of these helpless. This man was called a chief by the white traders, but neither he nor anyone else in that community had any such powers as chiefship implies. He had a great deal of influence but no authority.

While yet unchanged by civilization, the Eskimos seem to have been everywhere the healthiest and happiest people in the world. Disagreeing on many things, most travellers have agreed on this, especially regarding their happiness. By the common testimony of observers, they laugh as much in a month as ordinary civilized people do in a year, and they have all the other signs of contentment and well-being. There has been no agreement in explaining this, however. Some think it is a racial trait, some believe it to be due to the stimulating climate or to the outdoor life, and some think it is caused by the stimulating nature of the food. In certain Eskimo districts, such as western Alaska, vegetables were eaten to a considerable extent even before white men appeared, but there are many districts, such as Coronation Gulf, where nothing but flesh food is eaten even to-day. It required about twenty years at the mouth of the Mackenzie, from the time whaling ships began to winter there, before the Eskimos could be induced to eat any considerable proportion of white man's food, even where it was urged upon them. It will probably be twenty years (from 1910, when the first trader came there) before any considerable amount of vegetables begins to be eaten in Coronation Gulf.

The Eskimos are themselves well satisfied with their flesh foods and their clothes of hide and fur. They are equally satisfied with their country and climate. No "primitive" people is so difficult to induce to visit foreign lands, or so uniformly eager to get back after a season spent away. They are commonly looked upon by the world as an unfortunate people, but seem congenitally unable to grasp that point of view themselves.

ESKI-SHEHR, a town of Asia Minor, the capital of the vilayet of the same name. It is a station on the Haidar Pasha-Angora railway, 194½ m. from the former and 164 m. from Angora, and the junction for Konia; and is situated on the right bank of the Pursak Su (*Tembris*), a tributary of the Sakaria. Pop. (1927) 81,556. Eski-Shehr, *i.e.*, "the old town," lies about a mile from the ruins of the ancient Phyrgian Dorylaeum. The latter is mentioned in connection with the wars of Lysimachus and Antigonus (about 302 B.C.), and frequently figures in Byzantine history as an imperial residence and military rendezvous. It was the scene of the defeat of the Turks under Kilij-Arslan by the crusaders in 1097, and fell finally to the Turks of Konia in 1176. The town is divided by a small stream into a commercial quarter on low ground, in which are the bazaars, khans and the hot sulphur springs (122° F) which are mentioned as early as the 3rd century by Athenaeus; and a residential quarter on the higher ground. The town is noted for its good climate, the Pursak Su for the abundance of its fish. About 18 m. to the E. are extensive deposits of meerschaum.

ESMARCH, JOHANNES FRIEDRICH AUGUST VON (1823–1908), German surgeon, was born at Tönning, in Schleswig-Holstein, on Jan. 9, 1823, and died at Kiel on Feb. 23, 1908. He studied at Kiel and Göttingen, and in 1846 became B. R. K. von Langenbeck's assistant at the Kiel surgical hospital and in 1857 head of the general hospital and professor at the university. His attention had been directed to the subject of military surgery in the Schleswig-Holstein wars of 1848 and 1864, in which he had served in the field hospitals, and when the Franco-German War broke out in 1870 he was appointed surgeon-general to the army, and afterwards consulting surgeon at the great military hospital near Berlin. Esmarch was one of the greatest authorities on hospital management and military surgery. His *Handbuch der kriegschirurgischen Technik* (1877) is illustrated by admirable diagrams, showing the different methods of bandaging and dressing, as well as the surgical operations as they occur on the battlefield. Esmarch himself invented an apparatus, which bears his name, for keeping a limb nearly bloodless during amputation. No part of Esmarch's work is more widely known than that which deals with "First Aid," his *First Aid on the Battlefield* and *First Aid to the Injured* being popular manuals on the subject.

See H. Rohlfs, *Geschichte der deutschen Medizin* (Leipzig, 1885, vol. iv.).

ESMERALDAN, an independent linguistic stock of South American Indians, whose name is derived from the province of Esmeraldas in Ecuador. The Esmeraldan tribes occupied the coast region extending from the Bahia de Caraques northward to the mouth of the Esmeraldas river. They are now practically extinct. According to the early accounts these tribes artificially deformed the head. The men wore a short poncho-like shirt to the waist, the women an apron. Nose, ears and lips were pierced and gold, emerald and turquoise ornaments were worn in them.

The teeth were also inlaid with gold. The Esmeraldan tribes were sedentary, agricultural folk, raising also considerable cotton, which they wove into excellent cloth. Pottery was made, and they used both dug-out canoes and log rafts in coastwise trade. Their houses had reed walls, thatched roofs, and were grouped in large villages. They had special religious structures, in which were images. Child sacrifice was in use, the bodies being afterward flayed, the skin stuffed with straw and set up in their temples. The archaeological remains in this area, of which brief preliminary reports only have been made, suggest strongly an early cultural association of some sort with Central America.

See M. H. Saville, *Antiquities of Manabi* (Contributions to South American Archaeology, vols. I., II., Mus. Amer. Indian, New York City) R. Vernau and P. Rivet *Ethnographie ancienne de l'Equateur* (1912).

ESNA, a town of Upper Egypt on the west bank of the Nile, 484 m. S.S.E. of Cairo by rail, the railway station being on the opposite side of the river. Pop. 16,000, mostly Copts. Esna, one of the healthiest towns in Egypt, is noted for its manufactures of pottery and its large grain and live stock markets. There is considerable traffic with the oasis of Kharga, which lies almost due west of the town. Nearly in the centre of the town is the Ptolemaic and Roman temple of the ram-headed Khnūm, almost buried in rubbish and houses. The interior of the pronaos contains the latest known hieroglyphic inscription, dating from the reign of Decius (A.D. 249–251). In the neighbourhood are remains of Coptic buildings, including a subterranean church in the desert half a mile beyond the limits of cultivation. The name Esna is from the Coptic *Sne*. By the Greeks the place was called Latopolis, from the worship here of the latus fish. In the persecutions under Diocletian A.D. 303, the Christians of Esna, a numerous body, suffered severely.

ESOTERIC, having an inner or secret meaning. This term, and its correlative "exoteric," were first applied in the ancient Greek mysteries to those who were initiated (ἔσω, within) and to those who were not (ἔξω, outside), respectively. It was then transferred to a supposed distinction drawn by certain philosophers between the teaching given to the whole circle of their pupils and that containing a higher and secret philosophy which was reserved for a select number of specially advanced or privileged disciples. This distinction was ascribed by Lucian (*Vit. Auct.* 26) to Aristotle (*q.v.*), who, however, uses ἐξωτερικοὶ λόγοι (*Nic. Ethics*) merely of "popular treatises." It was probably adopted by the Pythagoreans and was also attributed to Plato. In the sense of mystic it is used of a secret doctrine of theosophy, supposed to have been traditional among certain disciples of Buddhism.

ESPAGNOLS SUR MER, LES, the name given to the naval victory of King Edward III. of England on Aug. 29, 1350, over a Spanish fleet commanded by Don Carlos de la Cerda, a Castilian freebooter, who had recently captured several English ships and murdered their crews. The English fleet assembled at Winchelsea early in August, King Edward commanding in chief in the cog. "Thomas"; the prince of Wales, Henry earl of Lancaster, Lord Scrope of Bolton and other members of the court also commanded ships. Their object was to cut off de la Cerda on his return from Sluys, where he had gone to collect merchandise. On the afternoon of Aug. 29 he appeared, running down the Channel with the north-east wind, with about 40 sail in all. Edward commanded about 50 ships, but they were inferior in build and size to the Spaniards who could fling missiles on them from their upper-works and tops. In addition, de la Cerda carried a strong force of Spanish cross-bowmen and Flemish mercenaries. He could easily have avoided action, as the English were close inshore when first sighted, but he had no wish to do so, and steered straight for them as they ran out from Winchelsea. King Edward's "Thomas" was severely injured on colliding with the first enemy, but he was able to grapple another and board and capture her just as the "Thomas" was about to sink.

The Spanish fire was very galling and did great damage, the prince of Wales being hard pressed till relieved by Henry of Lancaster, when the prince also boarded a Spaniard as his own ship was sinking. The ship carrying the king's household, commanded by Robert de Namur, was grappled by an enemy which began to tow her away. She would undoubtedly have been captured had not Hannekin, a squire of the commander's, boarded the Spaniard and cut her halliards and several shrouds and stays with his sword, thus bringing down her mainsail, so that she was brought to a standstill and captured instead. By night time the English had had the best of the action, the number of ships they captured varying in different accounts from 14 to 26. They suffered heavily, however, in casualties and had at least two ships sunk.

See Sir N. H. Nicolas, *A History of the British Navy* (1847).

ESPALIER, a lattice-work or row of stalks, originally shoulder high, on which fruit trees, shrubs and flowers, particularly roses and creepers, are trained. Espaliers are usually made of larch or other wood, iron and metal rails being too great conductors of heat and cold. The advantage of this method of training is that the fruit, etc., is more easily got at, and while protected from wind is freely exposed to sun and air, and not so open to extreme changes of temperature as when trained on a wall. (*See* HORTICULTURE.)

ESPARTERO, BALDOMERO (1792–1879), duke of Vitoria, duke of Morella, prince of Vergara, Count Luchana, knight of the Toison d'Or, etc., Spanish soldier and statesman, was born at Granatulu, a town of the province of Ciudad Real, on Feb. 27, 1792. He was the son of a carter, who wanted to make him a priest, but the lad at 15 enlisted in a battalion of students to fight against the armies of Napoleon I. In 1815 he went to America as a captain under General Morillo, who had been made commander-in-chief to quell the risings of the colonies on the Spanish Main. For eight years Espartero distinguished himself in the struggle against the colonists. He was several times wounded, and was made major and colonel on the battlefields of Cochabamba and Sapachni. He had to surrender to Sucre at the final battle of Ayacucho, which put an end to Castilian rule. He returned to Spain, and, like most of his companions in arms, remained under a cloud for some time.

Espartero became in 1832, on the death of King Ferdinand VII., one of the most ardent defenders of the rights of the daughter, Isabella II. The Government sent him to the front, directly the Carlist War broke out, as commandant of the province of Biscay, where he severely defeated the Carlists in many encounters. At times he showed qualities as a *guerrillero* quite equal to those of the Carlists, like Zumalacarregui and Cabrera, by his daring marches and surprises. Twice he obliged the Carlists to raise the siege of Bilbao before he was appointed commander-in-chief of the northern army on Sept. 17, 1836, when the tide of war seemed to be setting in favour of the pretender in the Basque provinces and Navarre, though Don Carlos had lost his ablest lieutenant, the Basque Zumalacarregui. In Nov. 1836 he again forced the Carlists to raise the siege of Bilbao. His troops included the British legion under Sir de Lacy Evans. This success turned the tide of war against Don Carlos, who vainly attempted a raid towards Madrid. Espartero was soon at his heels, and obliged him to hurry northwards, after several defeats. In 1839 Espartero carefully opened up negotiations with Maroto and the principal Carlist chiefs of the Basque provinces. These ended in their accepting his terms under the famous convention of Vergara. Espartero was styled "El pacificador de España," was made a grandee of the first class, and received two dukedoms.

During the last three years of the war Espartero, who had been elected a deputy, exercised from his distant headquarters such influence over Madrid politics that he twice hastened the fall of the cabinet, and obtained office for his own friends. At the close of the war the queen regent and her ministers attempted to elbow out Espartero and his followers, but a *pronunciamiento* ensued in Madrid and other large towns made the marshal prime minister. He soon became virtually a dictator, as Queen Christina resigned and left the kingdom very soon afterwards. The Cortes elected Espartero regent by 179 votes to 103 in favour of Arguelles, who was appointed guardian of the young queen. For two years Espartero ruled Spain in accordance with his Radical

and conciliatory dispositions, giving special attention to the reorganization of the administration, taxation and finances, declaring all the estates of the church, congregations and religious orders to be national property, and suppressing the *diezma*, or tenths. He suppressed the Republican risings with as much severity as he did the military *pronunciamientos* of Generals Concha and Diego de Leon. The latter was shot in Madrid.

Espartero crushed with much energy a revolutionary rising in Barcelona, but on his return to Madrid was so coldly welcomed that he perceived that his prestige was on the wane. The advanced Progressists coalesced with the partisans of the ex-regent Christina to promote *pronunciamientos* in Barcelona and many cities. The rebels declared Queen Isabel of age, and, led by General Narvaez, marched upon Madrid. Espartero embarked at Cadiz on July 30, 1843, for England, and lived quietly apart from politics until 1848, when a royal decree restored to him all his honours and his seat in the senate. He retired to his house in Logroño, which he left six years later, in 1854, when called upon by the queen to take the lead of the powerful Liberal and Progressist movement which prevailed for two years. The old marshal vainly endeavoured to keep his own Progressists within bounds in the Cortes of 1854–56, and in the great towns, but their excessive demands for reforms and liberties played into the hands of a clerical and reactionary court and of the equally retrograde governing classes. The growing ambition of General O'Donnell constantly clashed with the views of Espartero, until the latter, in sheer disgust, resigned his premiership and left for Logroño. O'Donnell's *pronunciamiento* in 1856 put an end to the Cortes, and the militia was disarmed, after a sharp struggle in the streets of the capital.

After 1856 Espartero resolutely declined to identify himself with active politics, and steadily refused office. King Amadeus made him prince of Vergara. The Restoration raised a statue to him near the gate of the Retiro Park in Madrid. Spaniards of all shades, except Carlists and Ultramontanes, paid homage to his memory when he died at his Logroño residence on Jan. 8, 1879. His tastes were singularly modest, his manners rather reserved, but always kind and considerate for humble folk. He was a typical Spanish soldier-politician, though he had more of the better traits of the soldier than of the arts of the statesman. His military instincts did not always make it easy for him to accommodate himself to courtiers and professional politicians.

See Florez, E., *Historia de su vida militar y politica* (1844–45); Mariano, *La Regencia de D. Baldomero Espartero* (1870); Pirala, A., *Historia de la guerra civil, con la regencia de Espartero* (1889).

ESPARTO or **SPANISH GRASS** (*Stipa tenacissima*), a grass resembling the ornamental feather-grass of gardens. It is indigenous to south Spain and north Africa (where it is known as Halfa or Alfa), and is especially abundant in the sterile and rugged parts of Murcia and Valencia, and in Algeria, flourishing best in sandy, ferruginous soils, in dry, sunny situations on the sea coast. It attains a height of 3 or 4 feet. The stems are cylindrical, and clothed with short hair, and grow in clusters of from 2 to 10ft. in circumference; when young they serve as food for cattle, but after a few years acquire great toughness. The leaves vary from 6in. to 3ft. in length, and are grey-green in colour; on account of their tenacity of fibre and flexibility they have for centuries been employed for making ropes, sandals, baskets, mats and other articles. Ships' cables of esparto, being light, float on water, and have long been in use in the Spanish navy.

Esparto leaves contain 56% by weight of fibre, or about 10% more than straw, and hence have come into requisition for the manufacture of paper. For this purpose they were first utilized by the French, and in 1857 were introduced into Great Britain. For paper-making the leaves should be gathered before they are quite matured; if, however, they are obtained too young, they furnish a paper having a semi-transparent appearance. The leaves are gathered by hand, and from 2 to 3cwt. may be collected in a day by a single labourer. They are generally obtained during the dry summer months, as at other times their adherence to the stems is so firm as often to cause the uprooting of the plants in the attempt to remove them. Esparto may be raised from seed, but cannot be harvested for twelve or fifteen years after sowing.

Another grass, *Lygeum Spartum*, with stiff rush-like leaves, growing in rocky soil on the high plains of the Mediterranean countries, especially Spain and Algeria, is also a source of esparto.

For the processes of the paper manufacturer esparto is used dry, and without cutting; roots and flowers and stray weeds are removed, and the material is then boiled with caustic soda, washed and bleached.

ESPERANCE, a small seaport on a natural harbour (Esperance Bay) on the south coast of W. Australia, 275 m. N.E. from Albany. Some importance attaches to it because of the large areas of wheat lands which are being opened up in the hinterland. The railway from Esperance to Salmon Gums is being extended to Norseman and Esperance will then tap the Norseman-Kalgoorlie gold-field area also.

ESPERANTO: *see* UNIVERSAL LANGUAGE.

ESPINEL, VICENTE MARTÍNEZ (1551–1624), Spanish poet and novelist. Expelled from the University of Salamanca in 1572, he served as a soldier in Flanders, returning to Spain in 1584 or thereabouts. He took orders in 1587, and four years later became chaplain at Ronda, absented himself from his living, and was deprived of his cure; but his musical skill obtained for him the post of choirmaster at Plasencia. His *Diversas Rimas* (1591) are undeniably good examples of technical accomplishment and caustic wit. Espinel, however, survives as the author of a clever picaresque novel entitled *Relaciones de la vida del Escudero Marcos de Obregón* (1618), from which Le Sage has not scrupled to borrow many of the incidents and characters in *Gil Blas*. Espinel also revived the *décima* known as *espinela*, a stanza of ten octosyllabic lines.

ESPIONAGE. The word "espionage" and its equivalents in most European languages are derived from a Germanic root which appears in the word *spähen*. The essential feature of espionage is its clandestine character. Espionage as practised between States may, therefore, be defined as "the attempt to obtain by clandestine means, for communication to a foreign government, information concerning another government which is likely to be injurious to that government."

The clandestine character of espionage lays it open to objection from the moral point of view; and espionage is, in fact, often practised by persons of undesirable character. As Montesquieu says, "Spying might perhaps be tolerable if it were done by men of honour; but the infamy which inevitably attaches to the agent is a criterion of the infamy of the practice." Individuals have taken the view that by practising espionage they were performing a necessary service to their own country. More generally, however, spies are recruited from among persons of doubtful character who are ready to undertake anything in order to earn money rapidly. The dangerous nature of the work has, moreover, a certain attraction for the adventurous.

Private Espionage.—Where the object is to obtain information on the conduct of an individual, or the progress of a business transaction, information may be obtained through conversation in ordinary social intercourse. Technical matters are dealt with by "information agencies" or private detectives. Private espionage also has recourse to even baser methods, such as the utilization of gossip collected from neighbours or from the doorkeepers of blocks of flats. In countries under an autocratic government, such as tsarist or Bolshevik Russia, and Fascist Italy, the political police authorities can obtain considerable assistance from doorkeepers; and the latter can, in periods of crisis, give important aid to the authorities (*e.g.*, at the time of the Commune of 1871).

Internal Political Espionage.—All governments employ spies, informers and secret agents, to keep them informed of the activities, views and relations of their opponents, or in some cases simply to acquaint them with the state of public opinion. The *sbirri* employed by the Venetian Republic are closely paralleled by the secret police of the French Revolution, the Holy Alliance and the tsarist régime. Agents of this kind penetrated into all strata of society, gained the confidence of conspirators, sometimes acted as *agents-provocateurs*, and sent in reports which varied in value according to the intelligence and character of the agent. They were, and still are, of considerable assistance to their gov-

ernments, so long, at any rate, as different departments do not each employ their own agents who work against one another, as happened in France under the First Empire. "Secret funds" are generally created for the organization of this kind of espionage and for the payment of secret agents. The funds are usually at the disposal of the heads of the government departments responsible for home affairs, foreign affairs, and the army and navy. In most modern countries their administration is not controlled by parliament.

In prisons and convict settlements the authorities employ spies known as "stool-pigeons" to discover plots for escape, to obtain confessions from prisoners, and in general to assist in ensuring punishment for all offences. The ex-convict Vidocq, when he became head of the Paris Sûreté in 1832, specialized in the employment of prison spies.

In political espionage, the spy very frequently acts as *agent-provocateur,* particularly during periods of crisis such as civil wars, revolutions and religious persecutions. Skilful use of espionage was made in England by Burleigh and Walsingham in Elizabeth's reign, and in France under Louis XIII. and Louis XV., by the Lieutenants of Police d'Argenson, Berryer and Sartines. Louvois set spies to watch over the conduct of his officers—a practice which has often recurred.

Fouché, who was minister of police from 1799 to 1802 and from 1804 to 1810, may be regarded as the real creator of political espionage, which he used to foil the numerous plots concocted by Jacobins, royalists, *émigrés* and *Chouans* during the Consulate and the Empire. In Russia, the famous Okhrana, or defensive police, was founded in 1881 to combat terrorism. It has been proved that Azeff, who was a member of the Central Committee of the People's Party, Pope Gapone, who played an important part in the revolution of 1905, and Malinowski, one of the deputies in the Duma, were all agents of the Okhrana. The Okhrana was responsible for the assassination of the Grand Duke Sergius, and of the ministers Plehve and Stolypin. Its activities reached their height in the period 1906–17. The famous Cheka, or "extraordinary commission for the repression of the counter-revolution and of speculation," continued the methods of the Okhrana and applied them to the opponents of the Bolsheviks. Since 1925 the Cheka has been replaced by the G.P.U.

Political espionage is sometimes practised in the international sphere. The Holy Alliance covered Europe with a network of spies. It had informers, *agent-provocateurs* and spies among the various groups of political *émigrés* in Paris and London. Heinrich Heine, Mürger, Princess Lieven and the Countess Kalergis are stated to have sent information to the Cabinets of Vienna and St. Petersburg (Leningrad). Similarly, international espionage has been used to combat the activities of anarchists.

Diplomatic Espionage in Peace-time.—The duties of diplomatic agents in peace-time include, not only the carrying out of negotiations and the protection of nationals of their country resident abroad, but also observation of what goes on in the countries to which they are sent. They are required to obtain accurate information on current events and on all matters which, directly or indirectly, affect the interests of the country they represent, even if such matters would normally appear to fall outside their sphere of action.

Modern diplomacy originated in the Italian cities of the middle ages; and the early Italian ambassadors, particularly the Venetians, were exceedingly able spies. Modern ambassadors have a technical staff of military, naval, aeronautical, commercial and legal attachés, whose duty it is to collect accurate information on various branches of national activity in foreign countries. It is thus possible to say that "an ambassador is often nothing more than an honourable spy acting under the protection of the law of nations."

So long as a diplomatic agent maintains a correct attitude, and does not use unfair means such as bribing officials, or stealing documents, his activities are quite distinct from those which come under the definition of espionage. It has, however, often happened that diplomatic agents, such as ambassadors, consuls and attachés have failed to observe a correct attitude. Two examples will suffice. In 1811, Col. Czernicheff, Russian attaché in Paris, with the complicity of an employee of the ministry of war, named Michel, obtained access to certain documents and figures. He was suspected and watched, but made his escape. Michel was shot. The second instance is the incident of the German and Italian military attachés in the Dreyfus affair. (*See* DREYFUS and ANTI-SEMITISM.)

Military Espionage or Espionage Proper.—Military espionage differs to some extent in the methods which it employs, according to whether a state of war or of peace prevails. In modern times it is, therefore, usual to set up two central departments to organize the collection of information and to supervise the agents employed; a police department (such as the Okhrana, the *Sûreté Générale,* etc.) and a military department (Intelligence Service, *Bureau d'Etat Major,* etc.). The two, of course, maintain the necessary liaison with one another. It may happen at certain times, as in France after the Dreyfus affair, that the functions of the military intelligence department are, to some extent, handed over to the police authorities. On the other hand it is inevitable that in time of war the military department which acts in liaison with the police authorities should be predominant.

Acts of espionage are recorded in the Bible and by classical authors such as Xenophon and Caesar. Organized espionage did not however exist until the 17th century under Cromwell in England and Richelieu in France. Richelieu had a complete system of espionage, the head of which was Père Joseph, *l'éminence grise.* It was mainly diplomatic in character; military espionage was until much later left in the hands of the military authorities. Frederick the Great made great use of spies. It was he who said "Marshal de Soubise is always followed by a hundred cooks; I am always preceded by a hundred spies." Napoleon's spy service was as efficient as his police service. In peace time the marshals who were in command of the forces stationed near the frontiers employed spies paid out of the secret funds. In war time the spy service was placed under the control of Gen. Savary. One of his most famous agents was Schülmeister, who played an important part in the campaign of 1805. He acted for both sides, conveying information both to Mack and to Savary. By supplying false intelligence, he fostered the irresolution and inertia of the Austrian general, who finally capitulated at Ulm.

In Germany the development of the espionage system dates from the middle of the 19th century. The secret police of the kingdom of Prussia was made into an independent, modern and specialized organization with a chief of its own, and had to keep watch over the internal and external safety of the country. Under the direction of Stieber the German espionage organization prepared the way for the campaigns which preceded the establishment of German unity: the Bohemian campaign of 1866 and the Franco-Prussian war of 1870–71. Stieber himself, disguised in various ways, visited Bohemia and facilitated the triumphal march of the Prussian forces to Sadowa. The preparations for the French campaign were made on a still more extensive and systematic scale. It was estimated that there were about 30,000 German spies in France in 1870. There was a complete system of local agents, travelling supervisors and regional commissioners. When the army was mobilized, Stieber was appointed head of the military intelligence. His duties included keeping watch over the army headquarters and over the personal safety of important personages, the supervision of correspondence, and above all the collection of information on the movements and strength of the enemy forces, and the state of public opinion and the available resources in the districts through which the German army passed. Zerniki, Stieber's lieutenant, made the preparations for the king of Prussia's entry into Versailles, and organized a system of espionage in that town. It has been proved that what took place in Paris during the siege was accurately known to the German staff; references to this state of affairs may be found in Alphonse Daudet's *Contes du Lundi.*

The Japanese made equally careful preparations for their campaign in Manchuria in 1904–05. Thus, although the Japanese army was relatively ill provided with cavalry, it was always well informed of the movements of the Russians, while its own changes

of position were masked by a screen of Chinese spies who were accepted by the Russians as inhabitants of the country.

Germany took as careful precautions for the World War of 1914–18 as for that of 1870. Espionage was facilitated by the large number of German nationals who were settled in foreign countries, and by the wide extension of German trade. The eastern departments of France in particular were riddled with German agents—agricultural workers, domestic servants, hairdressers, commercial travellers, German teachers, etc., many of whom gave themselves out as Belgians, Swiss or Luxembourgeois. The number of espionage and treason cases tried during the war shows how widespread was the German espionage system. The most famous trial was that of the woman spy Mata-Hari, a native of the Dutch East Indies, who was shot at Vincennes. The Governments of various countries found it necessary to put up posters in public places drawing attention to the necessity of discretion in conversation. "Be silent, be on your guard, enemy ears are listening" said the French posters. A part somewhat similar to that of the military intelligence departments was played by the inhabitants in the occupied areas, who endeavoured to help their own government and embarrass the armies of occupation. A number of French, Belgian and British of both sexes paid with their lives for acts of patriotic espionage. Two conspicuous instances are Nurse Cavell, who was shot by the Germans for having assisted escaped allied prisoners and helped them to make their way to neutral countries, and Louise de Bettignies, a Frenchwoman who was sentenced on similar grounds and died in prison.

Neutral countries, particularly those adjoining the belligerent countries, were important centres of espionage: witness Italy up to 1915, Greece, the Netherlands, the United States and Argentina. Nor did espionage end with the war, and there are many facts to prove that it still goes on, even between countries which are in close alliance with each other.

Methods of espionage vary with the object in view. Two things have to be done: information has to be obtained, and it then has to be communicated to the authority which requires it. In obtaining information, spies either act for themselves or bribe other persons who have access to the information which they require. In this, money and women's wiles both play an important part, as is shown by all the spy trials which have taken place at various times. In communicating the information received, when this cannot be done by word of mouth, all possible means are used, from ciphers and codes to the various signals employed in war time. In this matter great inventiveness has been shown by spies, their employers, and counter-espionage agents.

Many methods are employed to combat espionage. They may be classified as follows:

(1) Violent reactions of public opinion. The crowd suddenly turns on the spy or suspected spy, and there is a spontaneous outbreak of lynching. Incidents of this kind often occur during times of war or revolution, and spy-mania leads to terrible scenes of brutality and to gross miscarriages of justice.

(2) Technical protection in the form of counter-espionage. This exists in private as well as in diplomatic and military espionage. Its object is to discover and foil the ruses of the other side, and to neutralize its successes. The military and police departments responsible for espionage also carry out counter-espionage, and it sometimes happens that the same agents are employed for both purposes, and are thus in the pay of both sides.

(3) Diplomatic action to combat diplomatic espionage. A government which discovers that the diplomatic agents of a foreign Power have been guilty of incorrect behaviour towards it can demand their recall, although the agents in question are protected by diplomatic immunity. This may result in the breaking off of diplomatic relations, as occurred in Great Britain as a result of the activities of the agents of Soviet Russia which led to the police raid on Arcos ltd. in 1927.

(4) Penal measures against military espionage. The authorities responsible for action of this kind and also the severity of the penalties differ according as the countries concerned may be at peace or at war. Even in peace time heavy penalties of fine and imprisonment are imposed for espionage. Cases are tried by the ordinary courts, in camera if necessary. In war time, spies are court-martialled; and death becomes the normal penalty. Attempts have been made at several international conferences to arrive at uniform rules for the repression of espionage, *e.g.*, the Brussels Conference of 1874, and the Hague Conference which adopted the Convention of 1907. These conferences defined the distinctive character of espionage as residing in its clandestine nature, settled questions relating to guides, aeronauts, and the inhabitants of districts occupied by an invader, and dealt with the trial of spies. Unfortunately, not all countries have accepted the rules laid down, or have observed them in time of war.

(5) It may be hoped that the League of Nations may render mutual espionage less and less necessary since, with a view to preparing the way for a future limitation of armaments, it has undertaken the publication of extremely detailed annual statistics of the military and naval strength of the various states which are members of the league.

ESPIRITO SANTO, a maritime State of Brazil, bounded north by Bahia, east by the Atlantic ocean, south by Rio de Janeiro, and west by Minas Geraes. Pop. (1920) 457,328. Area, 17,248 sq.m. With the exception of Sergipe it is the smallest of the Brazilian States. The western border of the State is traversed by low ranges of mountains forming a northward continuation of the Serra do Mar. The eastern part of the State belongs to the coastal plain, in great part low and swampy, with large areas of sand barrens, and broken by isolated groups and ranges of hills. With the exception of these sandy plains the country is heavily forested, even the mountain sides being covered with vegetation to their summits. The northern and southern parts are fertile, but the central districts generally are comparatively poor. The inland valleys and slopes are very fertile and heavily forested, and much of the Brazilian export of rosewood and other cabinet woods is drawn from this State. There is only one good bay on the coast, that of Espirito Santo, on which the port of Victoria is situated. The river-mouths are obstructed by sand bars and admit small vessels only. The principal rivers of the State are the Mucury, which rises in Minas Geraes and forms the boundary line with Bahia, the Itaunas, São Domingos, São Matheus, Doce, Timbuhy, Santa Maria, Jucú, Benevente, Itapemirim, and Itabapoana, the last forming the boundary line with Rio de Janeiro. The Doce, São Matheus, and Itapemirim rise in Minas Geraes and flow entirely across the State. The lower courses of these rivers are generally navigable, that of the Rio Doce for a distance of 90 miles. The climate of the coastal zone and deeper valleys is hot, humid and unhealthy, malarial fevers being prevalent. In the higher country the temperature is lower and the climate is healthy. Espirito Santo is almost exclusively agricultural, sugar-cane, coffee, rice, cotton, tobacco, mandioca and tropical fruits being the principal products. Agriculture is in a very backward condition, however, and the State is classed as one of the poorest and most unprogressive in the republic. The rivers and shallow coast waters are well stocked with fish, but there are no fishing industries worthy of mention. There are three railway lines in operation in the State—one running from Victoria to Cachoeira do Itapemirim (50 m.), and thence inland to Manhuassu and Carangola, another line, reaching Santo Eduardo in Rio de Janeiro (58 m.), where connection is made with the Leopoldina system running into the national capital, and a third railway running north-westerly from Victoria to Diamantina, Minas Geraes, about 450 miles. The chief cities and towns of the State, with their populations in 1920, are Victoria (municipality, 21,866); São Matheus (municipality, 14,497), on a river of the same name 16 m. from the sea; Serra (municipality, 6,777); Guarapary (municipality), a small port

(10,904); south by west of the capital; Conceicão da Barra (municipality, 5,514); the port of São Matheus (12,000); and Cachoeira do Itapemirim (46,102), an important commercial centre in the south.

Espirito Santo formed part of one of the original captaincies which were given to Vasco Fernandes Coutinho by the Portuguese Crown. The first settlement (1535) was at the entrance to the bay of Espirito Santo, and its name was afterwards given to the bay and captaincy. It once included the municipality of Campos, now belonging to the State of Rio de Janeiro.

The islands of Trinidad and Martim Vaz, which lie about 715 m. E. of Victoria, belong politically to this State. They are uninhabited, but considerable importance is attached to the island of Trinidad because Great Britain has twice attempted to take possession of it. It rises 1,200 ft. above sea-level and is about 6 m. in circumference, but it has no value other than that of an ocean cable station. An excellent description of this singular island is to be found in E. F. Knight, *Cruise of the "Alerte"* (1895).

ESPOZ Y MINA, FRANCISCO (1781–1836), Spanish guerrillero leader and general, born at Ydozin, Navarre, June 17, 1781. He enlisted in Doyle's regiment in 1808, passed to the guerrilla band commanded by his nephew Xavier Mina, was made commander of the guerrilleros of Navarre (April 1, 1810), and commander-in-chief in Upper Aragon and on the left bank of the Ebro (Sept. 7, 1812). A successful strategist and excellent organizer, he compelled the French authorities to allow him to levy customs dues on all goods imported into Spain, except contraband of war, which he would not allow to pass without fighting. With the money thus obtained he paid a regular salary to his bands whom he had brought to a respectable state of efficiency in 1812. Espoz y Mina served with distinction under the duke of Wellington (1813–14). After the restoration of Ferdinand he fell into disfavour; involved in the Liberal Party plot at Pamplona (Sept. 25–26), he went into exile, and at the revolution of 1820 served the Liberal Party in Galicia, Leon and Catalonia. In 1823 he fled to England, took part in an unsuccessful rising against Ferdinand in 1830; recalled to Spain under the regent Christina, he was given the command against the Carlists in 1835. He resigned in April of the same year for reasons of health; his later command in Catalonia was only memorable for the part he took in forcing the regent to grant a constitution (Aug. 1836). He died at Barcelona on Dec. 24, 1836.

See F. Espoz y Mina, *Memorias* (Madrid, 1851–52); *A Short Extract from the Life of General Mina* (Eng. and Span. text, London, 1825).

ESPRONCEDA, JOSÉ DE (1808–1842), Spanish poet, was born at or near Almendralejo de los Barros. In his 14th year he joined a secret society and, sentenced to five years' seclusion in the Franciscan convent at Guadalajara, began an epic poem entitled *El Pelayo.* He escaped to Portugal and thence to England, where he found the famous Teresa whom he had met at Lisbon. In 1830 he eloped with her to Paris, took part in the July revolution, and soon after joined the raid of Chapalangarra on Navarre. In 1833, at the amnesty, he obtained a commission in the queen's guards; but this he soon forfeited by a political song. Banished to Cuéllar, he wrote a poor novel entitled *Sancho Saldaña ó el Castellano de Cuéllar* (1834). He took an active part in the revolutionary risings of 1835 and 1836; in 1840 he was appointed secretary of legation at The Hague; and in 1842 he was elected deputy for Almería; but death cut short his parliamentary career. His poems (1840) at once gained for him a reputation which still continues undiminished. The influence of Byron pervades Espronceda's life and work. It is present in an ambitious variant on the Don Juan legend, *El Estudiante de Salamanca,* Elvira's letter being obviously modelled on Julia's letter in *Don Juan;* the *Canción del Pirata* is suggested by *The Corsair;* and the Byronic inspiration is not wanting even in the noble fragment entitled *El Diablo Mundo,* based on the story of Faust. But in *El Mendigo,* in *El Reo de Muerte,* in *El Verdugo,* and in the sombre vehement lines, *A Jarifa en una orgía,* Espronceda proves himself one of the most potent and original lyrical poets produced by Spain during the 19th century.

See E. Rodríguez Solís, *Espronceda; su tiempo, su vida, y sus obras* (1883); J. Cascales Muñoz, *D. José de Espronceda* (1914).

ESQUIMAULT. A naval and military station situated on the south of Vancouver island, British Columbia, and connected by an electric railway to Victoria and Nanaimo. It has an excellent harbour, navy yard, meteorological station and barracks for naval and military purposes, all of which have been handed over to the Canadian Government by the British Admiralty. A large salmon cannery and a ship-yard provide the principal industrial interest. Pop. 5,100.

ESQUIRE, originally the attendant on a knight, whose helm, shield and lance he carried at the tournament or on the field of battle. The esquire ranked immediately below the knight bachelor, and his office was regarded as the apprentice stage of knighthood. The title was regarded as one of function, not of birth, and was not hereditary. In time, however, its original significance was lost sight of, and it came to be a title of honour, implying a rank between that of knight and valet or gentleman, as it technically still remains. Thus in the later middle ages esquire (*armiger*) was the customary description of holders of knight's fees who had not taken up their knighthood, whence the surviving custom of entitling the principal landowner in a parish "the squire" (*see* SQUIRE). Camden, at the close of the 16th century, distinguished four classes entitled to bear the style: (1) The eldest sons of knights, and their eldest sons, in perpetual succession; (2) the eldest sons of the younger sons of peers, and their eldest sons, in like perpetual succession; (3) esquires created by royal letters patent or other investiture, and their eldest sons; (4) esquires by office; *e.g.,* justices of the peace and others who bear any office of trust under the Crown. To these the writer in the 3rd edition of the *Encyclopædia Britannica* (1797) added Irish peers and the eldest sons of British peers, who, though they bear courtesy titles, have in law only the right to be styled esquires. Officers of the king's courts, and of the royal household, counsellors at law and justices of the peace he described as esquires only "by reputation"; and justices of the peace have the title only as long as they are in commission; while certain heads of great landed families are styled "esquires" by prescription.

It is clear, however, that the title of esquire was very loosely used at a much earlier date. On this point Selden is somewhat scornfully explicit. "To whomsoever, either by blood, place in the State or other eminency, we conceive some higher attribute should be given, than that sole Title of Gentleman, knowing yet that he hath no other honorary title legally fixed upon him, we usually style him an *Esquire,* in such passages as require legally that his degree or state be mentioned; as especially in Indictments and Actions whereupon he may be outlawed. Those of other nations who are Barons or great Lords in their own Countries, and no knights, are in legal proceedings stiled with us, Esquires only. Some of our greatest Heralds have their divisions of Esquires applied to this day. I leave them as I see them, where they may easily be found." Coke, too, says that every one is entitled to be termed esquire who has the legal right to call himself a gentleman (2. *Institutes,* 688).

At the present time the following classes are recognized as esquires on occasions of ceremony or for legal purposes: (1) All sons of peers and lords of parliament during their fathers' lives, and the younger sons of such peers, etc., after their fathers' deaths; the eldest sons of peers' younger sons, and their eldest sons for ever. (2) Noblemen of all other nations. (3) The eldest sons of baronets and knights. (4) Persons bearing arms and the title of esquire by letters patent. (5) Esquires of the Bath and their eldest sons. (6) Barristers-at-law. (7) Justices of the peace and mayors while in commission or office. (8) The holders of any superior office under the Crown. (9) Persons styled esquires by the sovereign in their patents, commissions or appointments. (10) Attorneys in colonies where the functions of counsel and attorney are united (in England solicitors are "gentlemen," not "esquires").

In practice, however, the title of esquire, now to all intents and purposes meaningless, is given to any one who "can bear the port, charge and countenance of a gentleman." The word has followed the same course as that of "gentleman" (*q.v.*), and for very simi-

lar reasons. It is still not customary in Great Britain to address, *e.g.*, a well-to-do person engaged in trade as esquire at his shop; it would be offensive not to do so at his private residence. In America, on the other hand, the use of the word "esquire" is practically obsolete, "Mr." ("Mister" or "Master," at one time the title special to a "gentleman") being the general form of address.

See Selden, *Titles of Honor* (1672); Camden, *Britannia* (ed. 1594); Coke, *Institutes; Enc. of the Laws of England, s.v.* "Esquire"; Du Cange, *Glossarium, s.v.* "Scutarius," "Scutifer" and "Armiger" (ed. 1886). (W. A. P.)

ESQUIROL, JEAN ÉTIENNE DOMINIQUE (1772–1840), French alienist, was born at Toulouse on Feb. 3, 1772. In 1794 he became a pupil at the military hospital of Narbonne, and subsequently studied in Paris at the Salpêtrière under P. Pinel, whose assistant he became. In 1811 he was chosen physician to the Salpêtrière, and in 1817 he began a course of lectures on the treatment of the insane, which led to the appointment of a commission to inquire into the subject. The asylums of Rouen, Nantes and Montpellier were built in accordance with his plans. In 1823 he became inspector-general of the university of Paris for the faculties of medicine and in 1826 chief physician of the asylum at Charenton. He died in Paris on Dec. 13, 1840. Esquirol's principal work is *Des maladies mentales, considérées sous les rapports médicaux, hygiéniques, et médico-légaux* (1838), which provides the first rational, scientific treatment of the subject. He first sketched out the main forms of insanity, and was the founder of a great school of French alienists who developed the work he had begun. See INSANITY.

ESQUIROS, HENRI FRANÇOIS ALPHONSE (1812–1876), French writer, born in Paris on May 23, 1812, was fined and imprisoned for his *L'Évangile du peuple* (1840). He was elected in 1850 as a Social Democrat to the legislative assembly, but was exiled in 1851 for his opposition to the Empire. Returning to France in 1869 he was again a member of the legislative assembly, and in 1876 was elected to the senate. He died at Versailles on May 12, 1876. Among his numerous works on social subjects may be noted: *Histoire des Montagnards* (2 vols., 1847); *Paris, ou les sciences, les institutions et les moeurs au XIX^e siècle* (2 vols., 1847), and *Histoire des martyrs de la liberté* (1851).

ESS, JOHANN HEINRICH VAN (1772–1847), German Catholic theologian, was born at Warburg, Westphalia, on Feb. 15, 1772. He became a Benedictine, and served as a priest at Schwalenberg from 1799 to 1812, after which, until 1822, he was professor of theology and joint-director of the teachers' seminary at Marburg. He died at Affolderbach in the Odenwald on Oct. 13, 1847.

His publications include a German trans. of the New Testament (1807); *Auszüge aus den heiligen Vätern u. anderen Lehrern der kath. Kirke über das nothwendige u. nützliche Bibellesen* (1808); *Gedanken über Bibel u. Bibellehre* (1816); *Was war die Bibel den ersten Christen* (1816); a German trans. of the Old Testament (1822–36); an edition of the Vulgate (1822–24) and of the Septuagint (1824).

ESSAD (*c.* 1875–1920), Turkish pasha and Albanian leader, sprang from the rich Albanian family of the Toptani, and was born at Elbasan. He entered the political service of the Sultan 'Abdul Hamid, and when the Turkish Revolution broke out joined the new movement and was deputy for Albania in the first Turkish Parliament. His influence over the somewhat uncertain Albanian population, and the desire of the Constantinople Government not to have so exceedingly cunning and skilful a man for their enemy, led to his being given, in 1912, the high command at Scutari, then under siege by the Montenegrins, though he knew almost nothing of military matters. But the town commandant Hasan Riza was the soul of the defence of Scutari; and, in order to have a free hand for his own secret dealings with the Montenegrins, Essad had him assassinated on Jan. 13, 1913. On April 25 Essad took the lead in the unreal and theatrical ceremony of handing over the fortress to Montenegro, but when the princedom of Albania was constituted after the Balkan War, Essad became Minister of War and also Minister of the Interior to William of Wied, and brought his policy into close touch with that of Italy. During the World War he was president of the Albanian delegation in Paris, but appeared at frequent intervals at Salonika and on the Albanian front as a guerrilla leader. He succeeded in bringing about the overthrow, by a so-called National Assembly in Cusonio, of the "Provisional Government of Durazzo," which was under Italian influence, and this National Assembly purposed to proclaim Essad King of Albania. But on June 13, 1920, he was killed in front of the Hotel Continental in Paris by Aveni Rustam, an Albanian.

ESSARTAGE: *see* AGRICULTURE, PRIMITIVE.

ESSAY, ESSAYIST. As a form of literature, the essay is a composition of moderate length, usually in prose, which deals in an easy, cursory way with a subject, and, in strictness, with that subject only as it affects the writer. Dr. Johnson, himself an eminent essayist, defines an essay as "an irregular, undigested piece"; the irregularity may perhaps be admitted, but want of thought, that is to say, lack of proper mental digestion, is clearly not characteristic of a fine example. It should, on the contrary, always be the brief and light result of experience and profound meditation, while "undigested" is the last epithet to be applied to the essays of Montaigne, Addison or Lamb. Bacon said that the Epistles of Seneca were "essays," but this can hardly be allowed. Bacon himself goes on to admit that "the word is late, though the thing is ancient." The word, in fact, was invented for this species of writing by Montaigne, who merely meant that these were experiments in a new kind of literature. This original meaning, namely that these pieces were attempts or endeavours, feeling their way towards the expression of what would need a far wider space to exhaust, was lost in England in the course of the 18th century.

Montaigne, in inventing the essay, had probably little suspicion of the far-reaching importance of what he had created. In his dejected moments, he turned to rail at what he had written, and to call his essays "inepties" and "sottises." But in his own heart he must have been perfectly aware that he had devised a new thing; that he had invented a way of communicating himself to the world as a type of human nature. It is not often that we can date with any approach to accuracy the arrival of a new class of literature into the world, but it was in the month of March 1571 that the essay was invented. Montaigne (*q.v.*) wrote slowly, not systematically; it took nine years to finish the two first books of the essays. The earliest imprint saw the light in 1580, at Bordeaux, and the Paris edition of 1588, which is the fifth, contains the final text of the great author. These dates are not negligible in the briefest history of the essay, for they are those of its revelation to the world of readers. It was in the delightful chapters of his new, strange book that Montaigne introduced the fashion of writing briefly, irregularly, with constant digressions and interruptions, about the world as it appears to the individual who writes.

It has always been admitted that Montaigne's genius has an affinity with the English. He was early read in England, and certainly by Bacon, whose is the second great name connected with this form of literature. It was in 1597, only five years after the death of Montaigne, that Bacon published in a small octavo the first ten of his essays. These he increased to 38 in 1612 and to 58 in 1625. It is possible that when he wrote them he was not yet familiar with the style of his predecessor, which was first made popular in England, in 1603, when Florio published his translation of the *Essais*. In the later editions Bacon greatly expanded his theme, but he never reached, or but seldom, the freedom and ease, the seeming formlessness held in by an invisible chain, which are the glory of Montaigne, and distinguish the typical essayist. It would seem that at first, in England, as in France, no lesser writer was willing to adopt a title which belonged to so great a presence as that of Bacon or Montaigne. The one exception was Sir William Cornwallis (d. 1631), who published essays in 1600 and 1617, of slight merit, but popular in their day. No other English essayist of any importance appeared until the Restoration, when Abraham Cowley wrote eleven "Several Discourses by way of Essays," which did not see the light until 1668. Cowley's essay "Of Myself" is a model of what these little compositions should be. The name of Bacon inspires awe, but it is really not he, but Cowley, who is the father of the English essay.

When we reach the 18th century, we find the essay suddenly be-

come a dominant force in English literature. It made its appearance almost as a new thing, and in combination with the earliest development of journalism. On April 12, 1700, appeared the first number of a penny newspaper, entitled the *Tatler*, a main feature of which was to amuse and instruct fashionable readers by a series of short papers dealing with the manifold occurrences of life. But it was not until Steele, the founder of the *Tatler*, was joined by Addison that the 18th century essay really started upon its course. It displayed at first, and indeed it long retained, a mixture of the manner of Montaigne with that of La Bruyère combining the form of the pure essay with that of the character study, as modelled on Theophrastus. Addison's early *Tatler* portraits, in particular such as those of "Tom Folio" and "Ned Softly," are hardly essays. But Steele's "Recollections of Childhood" is, and here we may observe the type on which Goldsmith, Lamb and R. L. Stevenson afterwards worked. In Jan. 1711, the *Tatler* came to an end, and was almost immediately followed by the *Spectator*, and in 1713 by the *Guardian*. Later in the century, after the publication of other less successful experiments, appeared Fielding's essays in the *Covent Garden Journal* (1752) and Johnson's in the *Rambler* (1750), the *Adventurer* (1752) and the *Idler* (1759). There followed a great number of polite journals, in which the essay was treated as "the bow of Ulysses in which it was the fashion for men of rank and genius to try their strength." Goldsmith reached a higher level than the Chesterfields and Bonnell Thorntons had dreamed of, in the delicious sections of his *Citizen of the World* (1760). After Goldsmith, the 18th century essay declined into tamer hands, and passed into final feebleness with the pedantic Richard Cumberland and the sentimental Henry Mackenzie. The *corpus* of 18th century essayists is extremely voluminous, and their reprinted works fill some 50 volumes.

A great revival of the essay took place during the first quarter of the 19th century, and foremost in the history of this movement must always be placed the name of Charles Lamb. He perceived that the real business of the essay, as Montaigne had conceived it, was to be largely personal. The *Essays of Elia* began to appear in the *London Magazine* for Aug., 1820, and proceeded at fairly regular intervals until Dec., 1822; early in 1823 the first series of them were collected in a volume. The peculiarity of Lamb's style as an essayist was that he threw off the Addisonian and still more the Johnsonian tradition, and boldly went back to the rich verbiage and brilliant imagery of the 17th century for his inspiration. He succeeded, moreover, in reaching a poignant note of personal feeling, such as none of his predecessors had ever aimed at; the essays called "Dream Children" and "Blakesmoor" are examples of this. Leigh Hunt, clearing away all the didactic and pompous elements which had overgrown the essay, restored it to its old *Spectator* grace, and was the most easy nondescript writer of his generation in periodicals such as the *Indicator* (1819) and the *Companion* (1828). The sermons, letters and pamphlets of Sydney Smith were really essays of an extended order. In Hazlitt and Francis Jeffrey we see the form and method of the essay beginning to be applied to literary criticism. The writings of De Quincey are almost exclusively essays. His biographical and critical essays are interesting, but they are far from being trustworthy models in form or substance. In a sketch, however rapid, of the essay in the 19th century, prominence must be given to the name of Macaulay. His earliest essay, that on Milton, appeared in the *Edinburgh Review* in 1825, very shortly after the revelation of Lamb's genius in "Elia." No two products cast in the same mould could, however, be more unlike in substance. In the hands of Macaulay the essay ceases to be a confession or an autobiography; it is strictly impersonal, it is literary, historical or controversial, vigorous, trenchant and full of party prejudice. The periodical publication of Macaulay's Essays in the *Edinburgh Review* went on until 1844.

In later times the essay in England has been cultivated both on the personal and on the impersonal model. The essays of R. L. Stevenson are of the same class as those of Montaigne and Lamb, and he approached far more closely than any of his contemporaries to their high level of excellence. In America in the meanwhile the essay had been written with genius by Thoreau in *Walden;* and Emerson's *Essays,* though not in the tradition of Montaigne and Lamb, were rich in lofty thought and utterance. The critical essay belongs, perhaps, to the sphere of criticism rather than of the essay, but a form so delightfully used by Matthew Arnold, Augustine Birrell and Edmund Gosse cannot be left unmentioned. Alice Meynell's *Essays* is perhaps the most beautiful book of essays ever written by a woman. During the 20th century the essay has been reborn as a playful kind of literature, and Max Beerbohm, Hilaire Belloc, G. K. Chesterton and E. V. Lucas are among those who have excelled in the art.

Although invented by a great French writer the essay was very late in making itself at home in France. The so-called *Essais* of Leibnitz, Nicole, Yves Marie André and so many others were really treatises. Voltaire's famous *Essai sur les moeurs des nations* is an elaborate historical disquisition in nearly 200 chapters. Later, the voluminous essays of Joseph de Maistre and of Lamennais were not essays at all in the literary sense. On the other hand, the admirable *Causeries du lundi* of Sainte-Beuve (1804–69) are literary essays in the fullness of the term, and have been the forerunners of much brilliant essay-writing in France. Among those who have specially distinguished themselves as French essayists may be mentioned Théophile Gautier, Paul de Saint-Victor, Anatole France, Jules Lemaître, Ferdinand Brunetière and Émile Faguet. All these are literary critics, and it is in the form of the analysis of manifestations of intellectual energy that the essay has been most successfully illustrated in France. All the countries of Europe, since the middle of the 19th century, have adopted this form of writing; such monographs or reviews, however, are not perfectly identical with the essay as it was conceived by Addison and Lamb. This last, it may be supposed, is a definitely English thing, and this view is confirmed by the fact that in several European languages the word "essayist" has been adopted.

See Hugh Walker, *The English Essay and Essayists* (1915); J. B. Priestley, *Essayists Past and Present* (1925).

ESSEN, a manufacturing town of Germany, in the Prussian Rhine province, 22 m. N.E. from Düsseldorf on the main line of railway to Berlin. Pop. (1925) 468,966. Essen was originally the seat of a Benedictine nunnery, and was formed into a town about the middle of the 10th century by the abbess Hedwig. The abbess of the nunnery governed the town until 1803, when it was secularized and incorporated with Prussia. In 1807 it came into the possession of the grand dukes of Berg, but was transferred to Prussia in 1814. In 1920 the Communists held, for a time, the factories, which were only retaken after heavy fighting. Occupied by the French after the Armistice, Essen was evacuated by them on Aug. 1, 1925.

Railways radiate from it to all the principal towns of the Westphalian iron and coal fields. The minster, dating from the 10th century, with fine pictures, relics and wall frescoes, is noteworthy and is very similar to the Pfalz-Kapelle (*capella in palatio*) at Aix-la-Chapelle. The town originally owed its prosperity to the large iron and coal fields underlying the basin in which it is situated. Chief among its industrial establishments are the famous iron and steel works of Krupp (*q.v.*), and the whole of Essen may be said to depend for its livelihood upon this firm, which now produces locomotives, agricultural machinery, etc., and was employing in 1925 some 35,000 workers. There are also manufactories of woollen goods and cigars, dyeworks and breweries.

ESSENES. (1) *Meaning.*—The Essenes, who included the Therapeutae and Hemerobaptists, were a body of pre-Christian Jews who lived a monastic life: whether they are to be regarded as a distinct sect is a matter of controversy. But there is general agreement that from the Maccabaean age and onward, if not earlier, there were individuals and brotherhoods known as Essenes and distinguished by characteristics such as the community of property, the practice of charity and the pursuit of virtue.

(2) *Sources.*—The sources of information about the Essenes are direct and indirect. To the former category belong Philo, Josephus and Pliny, who may be considered as of primary importance. Other writers of this category who speak of the Essenes as a whole, *e.g.*, Epiphanius, Hippolytus, Porphyry and Eusebius are secondary. The first-named seems to identify Essenes and Elkesaites, the accounts of the two next are based on Josephus

and the last cites Philo. Of the three none is entitled to the rank of an independent witness. Indirect information is occupied by the Rabbinical writings and the epithet indirect is employed because no connected account, such as is found in Philo, Josephus or Pliny occurs in Talmud or Midrash, but much valuable knowledge about individual Essenes is contained in these sources. Their purpose is not to provide a picture of a sect, favourable or unfavourable according to the predilections of the author. The mention of a given custom or a specific act is due to considerations of history or of *halakhah* (Canon Law): the circumstance that the actor or the followers of the custom may be identified as Essenes is a matter of modern interest but had little or no meaning to the authority by whom it happened to be recorded.

(3) *Names.*—Greek writers refer to the Essenes by names of which the most common are 'Εσσηνοί and 'Εσσαῖοι. The derivations are disputed. The English *Essene* comes, through the Latin, from 'Εσσηνοί. This form is unknown to Philo who invariably uses the alternative. Josephus uses both names, the former more frequently. Other writers who generally or exclusively prefer 'Εσσηνοί or *Esseni* are Solinus, Pliny, Synesius and Hippolytus, while Hegesippus and Porphyry favour 'Εσσαῖοι. Epiphanius has forms peculiar to himself; these are most probably corruptions or local variants. To what Hebrew or Aramaic equivalents may 'Εσσηνοί, 'Εσσαῖοι be referred? The problem is not easy to answer. Various solutions have been suggested but even after the Greek terms have been explained satisfactorily, there still remain the Rabbinic names, of a totally different style, which were applied to men who lived by a rule to all intent Essene and which must therefore be deemed to be as accurate designations of Essenes as those preserved in the Greek and Latin writings.

Philo equates 'Εσσαῖοι with ὅσιος: this is mere allegory and can hardly have been intended as etymology. The following derivations are suggested. From the Hebrew:—*Ḥashshā'im* (the silent ones): *'Asah* (he acted) and *'Anshē Ma'aseh* (men of action): *Ḥāzah* (he saw visions) and *Sāḥah* (he bathed). The first is the most probable: apart from other considerations no suitable adjectival forms exist from the verbs in the perfect tense given above. From the Aramaic:—*Ḥasē, Ḥāsen* with stat. emphat. *Ḥasāya* (pious), *'Asā* (he healed), 'Εσσηνοί may come from *Çenū'im* (chaste).

The Talmudic names are *Ḥaṣidim* (or *Zeqēnim*) *Ha-rishōnim* (the ancient Saints or elders); *Neqiyyē Had Da'ath* (the pure-minded); *Çenū'im* (the chaste); *Ḥashsha'im* (the silent ones); *Wattiqim* (men of exactitude): *Banna'im* (builders), etc.

(4) *Description.*—Philo (*Quod omnis probus liber*, secs. 12, 13), after describing the Persian Magi and the Indian Gymnosophists, reminds his readers that similar examples of virtuous people can be adduced from Judaism. He instances the Essenes, who lived in Palestine and Syria and who numbered about 4,000. He speaks again of the Essenes in his lost *Apology for the Jews*, which is preserved by Eusebius (*Prep. Evang.*, viii. 11). The Essenes were Communists: they supported themselves by manual labour (generally by agriculture, never by making weapons of war), the proceeds of which replenished the common fund. They were devoted to study, prayer, and acts of benevolence, especially towards the aged and sick. Some approved of conjugal intercourse under restricted conditions, *i.e.*, until children had been born; others abstained from marriage altogether. They recruited their ranks by adopting children who were young enough to imbibe their teaching or by accepting proselytes of a mature age who had reached a period when the allurements of the world would have lost their attraction. They condemned slavery in principle and practice: the younger ministered to the elder and the natural respect due to seniority and learning replaced the artificial claims of rank. They chose their rulers, maintained special codes, possessed their own secrets, traditionally preserved and imparted, in which angelology figured prominently. They had no single city of their own, however, but tended to congregate as a result of their mode of life and to concentrate in certain districts, notably on the western shore of the Dead sea. As a body they preferred the country to the city, yet we find individuals among them not infrequently taking part in political life. They despised pleasure and luxury, regarding anointing oil as particularly hateful and defiling. They wore simple white garments and did not own a change of clothes. They bathed in cold water, ate but a single dish and worked till sundown. They prayed before sunrise and at their meals grace was said by a priest. Their conduct was orderly and their conversation restrained.

In all their enterprises the leaders directed the procedure, and named the persons called upon to officiate; only in deeds of mercy and charity could the individual act independently. They objected to oaths, but an oath once taken was never capable of being annulled. Herein lay the chief disciplinary power of their officers, for since they observed strict purity in their food and refrained from eating anything which others had prepared, anyone excommunicated could soon be starved into obedience; cases of expulsion seem to have been almost unknown and instances of disobedience seem to have been rare. A novitiate of three years, divisible into two stages of increasing asceticism, was demanded of the postulant for admission. Josephus, who states that he underwent this probationary period but then resigned, must therefore be trusted in his accounts of the external life and tenets of the Essenes, but he cannot be regarded as having possessed an inner knowledge of their secrets, which the Essenes revealed only to those who joined their order. The oath exacted from the initiate, before he was allowed to share the common meal, is given by Josephus: "to be pious to the Deity, to practice justice towards men; never to injure anyone, either of his own accord or under compulsion: always to hate the wicked and side with the just: ever to show faithfulness to all mankind and to be true to those in authority, for all power comes from God: never when in office, to force his personal views or authority or to assume a special dress or luxury: to love truth and hate falsehood: to keep his hands pure of theft and his soul from unrighteous gain: not to have any secret from his brethren and never to betray one of theirs, even at the cost of his life: to pass on the traditions he himself had received: never to be a brigand: to safeguard the sacred books and to preserve with care the names of the angels that had been taught to him."

Sabbath observance was very strict: non-statutory sacrifices were avoided: in the society there were four grades, based on learning and seniority. They lived long, as a result of their simple habits and diet and neither bribery nor torture could make them false to their principles. Pliny (*Hist. Nat.* v. 17) describes the customs of the Essenes and terms them "a race by themselves, more remarkable than any other in the wide world." Philo, deeming one proof alone sufficient to establish his definition of the Essenes as "champions of virtue" says: "From time to time their country has been seized by many rulers . . . some more ferocious than wild beasts, surpassing every form of savagery, massacring hordes of their subjects, severing them limb from limb while alive. Yet none of these bloodthirsty tyrants has ever been able to lay a single charge at the door of an Essene." Josephus stresses the belief of the Essenes in the Resurrection and states that their doctrines were borrowed by the Pythagoreans and Stoics: he considers that the Essenes are the oldest of ascetics and that it was from Egypt that their doctrines spread abroad. He mentions also their addiction to prophecy and the foretelling of events.

(5) *History and Tenets.*—The chief problems concerning the Essenes are the following: Were they a distinct sect? what was their origin? how and why did they arise and disappear? The circumstance that the Essenes are known by a variety of designations, all of which are epithets describing their aims or beliefs, and none of which incorporates the name of a founder or the place where he lived, goes to prove that the Essenes were not a distinct, well-defined body to be segregated from the general mass of Jews. That they were a separate sect used to be the accepted view. It was held that foreign influences, Persian or Buddhist or Pythagorean or Syrian, were responsible for the Essenes and that their characteristic beliefs and practices were derived from some non-Jewish source. The four theories enumerated above had, each one, their distinguished advocates. The preponderating mass of Jewish material which forms the foundation of Essenism, must not be overlooked. The opposite view, that of Kohler, is, in the main, true: he regards the Essenes as "a branch of the Pharisees

who conformed to the most rigid rules of levitical purity while aspiring to the highest degree of holiness." Perhaps the extent to which non-Jewish thought is mirrored in Essenism is slightly greater than Kohler is disposed to concede, but Kohler is undoubtedly correct in his main thesis that the Essenes were essentially Jewish in origin, that they belonged to the Pharisees, and that they did not, on the whole, constitute a sect.

VARIETIES OF ESSENISM

That the term Essenism was a general one, and applicable to a variety of forms of belief is clear. Thus while the Essenes as a whole belonged to Palestine and Syria, the Therapeutae (θερα πευταί lit. "attendants" or "physicians": hence "worshippers of God") were to be found in Egypt, on the shores of Lake Mareotis, by Alexandria. Philo, who is the sole authority for their existence and who speaks of them in *De Vita Contemplativa*, distinguishes the contemplative Therapeutae from the remaining Essenes who lived a more practical life. Philo cannot account for the origin of the name Therapeutae and this circumstance tends to show the antiquity of these ascetics. The Alexandrian community lived in mean and scattered houses, near enough to afford mutual protection when necessary, but not too close to disturb the solitude which was so greatly prized. Each house contained a chamber called σεμνεῖον or μοναστήριον devoted to prayer and meditation (*cf.* Matt. vi. 6). During the week the Therapeutae lived apart and meditated in solitude, but on Sabbath they prayed and they ate in common. Their so-called feasts (where no flesh was served and only cold water was drunk) especially that held on the eve of Pentecost, were famous and formed a contrast to Greek revels. At these feasts the philosophical discourse was the chief feature. This was followed by hymns and by the *pervigilium*, celebrated with antiphonal and joint singing and with choral dancing in imitation of Moses and Miriam at the Red sea. In view of the habits of the Therapeutae, the existence of pre-Christian monasticism cannot be denied. Already in Philo's days the Therapeutae were considered to be ancient. Strabo, who was born in 63 B.C. and who visited Egypt before 25 B.C., speaks of buildings at Heliopolis which the priests had taken over from the former guilds of philosophers and scientists. He states that these learned men were consulted by Plato and Eudoxus but that the σύστημα and the ἄσκησις were extinct. Philo, describing the Therapeutae, makes use of these same technical terms. The Stoic philosopher Chaeremon, a contemporary of Strabo, records the σύστημα and ἄσκησις so that the line of continuity was not necessarily broken. Porphyry (*De Abstinentia*, iv. 6) preserves Chaeremon's account which resembles Philo's description of the Therapeutae, even including details such as their posture, gait and habit of eating hyssop with their bread. Incidentally it may be remarked that F. C. Conybeare has vindicated the genuineness of Philo's account against P. Lucius's endeavour to impugn its authenticity. Eusebius, struck by the resemblance of the Therapeutae to Christian monks, claimed them to be Christians converted by Mark. He was followed by various patristic writers and mainly on this account Lucius maintained that Philo's book *De Vita Contemplativa* was a later Christian forgery, intended to procure the sanction of Philo's name for the rising monasticism of the Church. It is, however, now generally acknowledged that Conybeare is correct and the Therapeutae are held to have been a variety of the Essenes, distinguished by a love of contemplative devotion.

Another division is that of the Hemerobaptists or *Tobele-Shaharith*, whose daily ablutions were a matter of ritual—John the Baptist may have belonged to them. Epiphanius (*Panarion*, I, 17) mentions them as the fourth heresy among the Jews, and classes them doctrinally with the Pharisees but, like the Sadducees, they are said to have denied the resurrection of the dead. Both Hegesippus and Justin Martyr speak of the Hemerobaptists.

Common to all the above mentioned varieties of the Essenes is the circumstance that each is described as forming a homogeneous body, ruled by officers acting in accordance with traditional laws and possessing initiatory oaths and ceremonies incumbent on the neophyte. The Greek sources make it clear that they are speaking of sects. On the other hand the Rabbinic writings speak of individuals or informal groups, lacking altogether the cohesion and permanence which the Greek imply. Probably both are correct, for allowance must be made for the fact that the Greek accounts are connected descriptions, possibly coloured by the desire to heighten parallels to other bodies, while in Rabbinic sources only incidental references occur and the comprehensive designation Essene is probably never met with. Little is said of the Essenes that does not fall within pharisaic category. Among the Pharisees were plenty of men who, singly, or collectively, lived the Essene life. (Büchlers *Types of Palestinian Piety* contains plenty of illustrations.) But they were not recluses. They were men of action who brought religion into life. Menahem, an Essene, predicted Herod's rise to power. Judas the Essene foretold the death of Antigonus. John the Essene was a general in the Roman War.

Probably the Essenes and Pharisees sprang from the pre-Maccabaean *Ḥasidim*. In later times we hear of the *Ḥasīdim ha-Rishōnim*, brotherhoods (*Ḥabūroth*) of pious men who waited in meditation before statutory services began "in order to attune their minds to their Father in Heaven" and who met also for common meals; of the *Neqiyyē had-Da'ath*, probably a more informal body of "pure-minded ones" who paid special reverence to the scroll of the law; of the *Çenū'im* or "chaste ones" among the priesthood and the *'Anāwim or* "humble ones," both elderly men who possessed and transmitted the secret of the divine name of 42 letters and who, copying Moses and Israel before Sinai, refrained from sexual intercourse in the hope of meriting a further revelation: of the *Ḥash-shā-'im*, or "reticent ones" to whom secret scrolls were entrusted: to the *Wattiqim*, or "men of exactitude" who so arranged their morning prayers that they finished the recital of the *Shema'* at the time of the sun's first brilliance, and of other groups.

In view of the foregoing it is hard to believe that the Essenes remained pent within a watertight compartment and that they are strictly to be differentiated from the mass of primitive Judaism, all the more as no comprehensive Hebrew name for them can be produced to justify such an assumption. An anonymous corporation can scarcely be conceived: supporters and opponents alike, would have felt the necessity for precision: an appellation or a taunt-word that would be indisputably applicable must inevitably have won popularity, just as the terms "Society of Friends" or "Quakers" unambiguously designate a definite religious body, and just as no doubt is entertained as to those to whom the term Pharisee refers. No such categorical epithet in Hebrew is known for the Essenes. The term Pharisee sufficed to cover all their subdivisions. For it cannot be argued that the Essene tenets lie far off the beaten track of Judaism. Abstinence is possibly the only exception and too much must not be made of the Greek writers' emphasis on this element. Nor is it unknown in the Talmud. Private fasts and asceticism are mentioned on many occasions. That they are deprecated is another matter. Judaism possesses enough official disciplinary abstinence to render it desirable to check the common impulse towards optional asceticism. But the desire of the individual to add to the statutory prescriptions was Jewish as well as Essene because it was natural in saints: it is found at all times and deprecated at all times by those who guide the common worshippers and who wisely strive to guard them against excess. Essene tenets can certainly not be detached. It is only by carefully gathering all instances of individual holiness and by segregating them as unusual in Judaism that the Essenes can be isolated. Having abstracted all the sweetness, the remaining drab gloom and ugliness is said to represent normal Judaism: this forms an agreeable foil to the Gospels. Not infrequently the motive for exalting the Essenes has been the desire to decry the spiritual outlook of Jesus' contemporaries.

DRAWN FROM ALL CLASSES

Moreover, the Essenes were drawn from all classes, they had their priests, which merely means that their ranks included pious *Cohanim*. In the same way their insistence on the immutable nature of oaths recalls the Sadducees and their objection to annulling vows. The often misunderstood "Corban" episode of the Gospels would show that Jesus followed the Pharisee view, for it

was they who insisted on dissolving, wherever possible, rash vows adversely affecting parents while the Essenes or Sadducees stood for the letter of the bond. The gospel writer has confused the controversialists and made Jesus appear to be blaming the Pharisees for the very principle on which they and he were in agreement against the Sadducees. If, therefore, Essenes included priests, Pharisees and Sadducees, they cannot have formed a definitely separate body. The term Essene can denote nothing more than "pious," in the vaguest sense of the word, allowing for all manner of divergencies according to the personal tastes of individuals and groups.

When we read that the Essenes accompanied the reading of the Law by expository homilies, we cannot doubt but that the reference is to Haggadic Midrash of which their secret books may well have consisted. Their angelology is not necessarily more foreign than much similar material contained in the *Haggadah* and which later developed into *Qabbalah*. Perhaps it is begging the question to take a Jewish origin and Jewish angelology for granted. Be this as it may, the presence of angelology among Essene beliefs is no argument for the foreign origin of general Essenism, just as little would it be logical to argue that Judaism as a whole is foreign because Judaism contains angelology which is foreign.

What is perhaps the most conclusive argument against the isolation of the Essenes is their imperceptible disappearance. The Sadducees vanished silently after A.D. 70 because the *raison d'être* of the priests disappeared with the Temple. But no such reason can explain why no more is heard of the Essenes, either in Judaism or in Christianity. They seem to have faded from history. The answer is that they assimilated their environment, they did not succumb to it. They imposed their mark on their contemporaries so impressively that they conquered. The communistic groups and the ascetic practices were a means to an end: the practice of virtue and the cult of saintliness, being part of the teaching of Judaism as of Christianity, ceased to be the distinctive mark of the Essene. When paganism lapsed, Essenism had achieved its purpose. The Essene, or his convert, became the good Christian or the good Jew. That a number of men of extraordinary piety should have influenced their generation and gradually raised the general level to their own height need excite no wonder. That the first men in the world to condemn the institution of slavery should have carried the teachers and saints of their age with them and should have merged and become lost as virtue spread and morality prevailed is no more surprising than that the groups which constituted the apostolic Church and which exhibited considerable varieties of outlook should have blended imperceptibly and with a gradual loss of individuality into the harmonious background of universal Christianity.

ESSENTIAL OILS. The terms *essential, ethereal* or *volatile oils* are applied to volatile odoriferous bodies of an oily character, obtained almost exclusively from vegetable sources. They must be distinguished from the two other great groups of naturally occurring substances with which they share the general name "oil," or for none but rather superficial reasons. Its minerals differ from them in consisting of hydro-carbons (compounds of carbon and hydrogen without oxygen; *see* PETROLEUM); the animal or vegetable oils, on the other hand, are oxygen-containing substances consisting mainly of esters (*q.v.*) belonging to the class of glycerides (*q.v.*), that is, compounds of glycerine (*q.v.*) or fatty acids (*q.v.*); they are discussed in the article OILS, FATS AND WAXES, and the more important of them in individual articles.

Occurrence.—The essential oils of plants are present, as a rule, in very small amounts; in cloves there is as much as 16–18% of oil, but rose petals yield as little as 0·2% of the essential oil, while from jasmine blossoms only $\frac{1}{10}$ of this quantity can be obtained. The oils may be found in special cells, glands or ducts, in one particular organ, or distributed over many parts of the plant, such as leaves, bark, roots, flowers or fruits. From the work of Charabot and others it appears that the oils are actually formed in the green (chlorophyll-bearing) parts of the plant, possibly as a result of pathological processes or as by-products of plant metabolism. As the plant matures the oils are transported to other tissues, in particular the flowering shoots, where secondary changes (oxidation, esterification, etc.) in the constitution of the oils may occur. In the case of the plants (lavender, peppermint, etc.) studied by Charabot, the oil content reached a maximum immediately before fertilisation of the flowers. At this stage there was notable consumption, or loss, of oil, the proportion of which further decreased as the fruits ripened. The quantity and composition of the essential oils of plants may vary with the conditions of cultivation, *e.g.*, light, climate, soil, altitude, etc., as is instanced by the different ester content of oils from lavender grown in England and the south of France.

Occasionally the odoriferous ethereal oils are not present as such in the living plant, but occur as scentless compounds of sugars termed *glucosides, e.g.*, amygdalin in bitter almonds, gaultherin in wintergreen, sinigrin of mustard seeds. When the tissues are macerated the ferment action of the enzymes present in the plant decomposes the glucosides, liberating the characteristically odorous ethereal oil.

Function.—The function of the oils in the plant is uncertain; they may be merely excretory by-products (*e.g.*, resins, oil of turpentine), or secretions for specific purposes, for example, to attract insects to the flowers: the high consumption of essential oil during the period of fecundation points to a possible nutritive value.

The animal secretions musk, ambergris, civet and castor, are considered in the separate articles under these headings and under PERFUMERY. The crude secretions are used in perfumery and no essential oils are separated. It is doubtful whether the odour of these bodies is due to volatile oils; recently, however, certain characteristic aromatic ketones have been isolated.

Physical Properties.—The volatile oils are mostly insoluble in water, but freely soluble in alcohol, ether, fatty and mineral oils. As a rule they are not oleaginous to the touch and leave no permanent grease-spot. They are usually liquid at ordinary temperatures; some, on standing, deposit solid matter (*stearoptenes*) which crystallise from the liquid remainder (*elaeoptene*), *e.g.*, oil of camphor, rose oil. In specific gravity the ethereal oils range from 0·85 to 1·142; they possess a high refractive power and the majority rotate the plane of polarised light.

The natural volatile oils consist usually of mixtures of several chemical individuals; the properties of the various components are in accordance with their chemical constitution, which determines the means to be employed for their identification and estimation.

The present state of our knowledge does not permit of strict correlation of odour and chemical constitution. The hydrocarbons have, on the whole, no pronounced odour; scent appears with the introduction of oxygen, nitrogen or sulphur in certain groups such as hydroxyl (OH), aldehyde (—CHO), nitrile (—CN), isothiocyanate (—SCN), etc., to the molecule, but particular groupings cannot be associated with particular types of odour. Different groups may have practically equal effects, for instance, benzaldehyde C_6H_5CHO and nitrobenzene $C_6H_5NO_2$ have almost identical odours. In the case of the synthetic musks, symmetrical arrangement in the benzene nucleus of the three nitro- (or substituted nitro- groups) seems to be essential to the production of odour.

Constitution.—The components of the ethereal oils are, as a rule, compounds of hydrogen, carbon and oxygen only; hydrocarbons occur to a considerable extent in some oils, *e.g.*, pinene in oil of turpentine; nitrogen and sulphur compounds are also found (*see* below). The constituents of the volatile oils may be classed in the following groups according to their chemical nature:—

(1) *Hydrocarbons, e.g.*, styrolene in storax; the terpenes (*q.v.*), *e.g.*, pinene in oil of turpentine, limonene in lemon and orange-peel oils. (2) *Alcohols* (*a*) straight chain, *e.g.*, linaloöl from oils of lavender, neroli and linaloe, geraniol in rose otto, palmarosa and citronella oils: (*b*) terpene alcohols, *e.g.*, borneol in Borneo camphor; terpineol in oils of linaloe, cajeput, etc., also artificially prepared from oil of turpentine for lilac odours: (*c*) phenols, *e.g.*, menthol

in oil of peppermint; thymol in thyme oil; eugenol in oil of cloves. (3) *Esters, e.g.*, isoamyl acetate, synthetic for pear flavour; methyl salicylate in oil of wintergreen, and synthesised from salicylic acid; geranyl acetate in oils of palmarosa, lemongrass, pettitgrain, etc., and synthesised from geraniol for rose and orange flower odours. The *acids* occasionally occur in the free state in natural oils, but have the greatest importance in combination as esters. (4) *Aldehydes, e.g.*, citral in lemongrass and lemon oils; citronellal from oil of lemon; benzaldehyde in oil of bitter almonds, laurel oil; vanillin in vanilla, gumbenzoin, etc., and artificially prepared from eugenol or guaicol; heliotropin (piperonal) in oil of spiraea, synthesised from safrole for heliotrope odour. (5) *Ketones, e.g.*, menthone in oil of peppermint; camphor in oil of camphor, ionone synthesised from citral for violet odours. (6) *Oxides and lactones, e.g.*, safrole from oils of sassafras and camphor; coumarin in tonka bean, woodruff, synthesised from salicylic aldehyde for "new mown hay" odours; eucalyptol (cineol) in oil of eucalyptus. (7) *Nitrogen* and *sulphur compounds, e.g.*, prussic (hydrocyanic) acid in oil of bitter almonds, laurel oil; nitrobenzene ("oil of mirbane") synthesised from benzene for almond odour; trinitrobutylxylene (Baur's xylene musk) synthesised from xylene for substitute musk: allylisothiocyanate in oil of mustard. Many other compounds exist and most are to be found in a variety of natural oils; only the principal sources can be quoted here.

Preparation.—Essential oils are obtained from plants by the following methods:—

(1) *Steam distillation*, the most important method, is applicable to the widest range of substances, *e.g.*, peppermint, camphor, cloves, etc.; it is especially favoured for the production of the more stable oils, such as oils of cedar, cloves, etc. (2) *Expression*, by hand (*"écuelle"* and *"éponge"*) or by machinery, used almost entirely for the production of oils contained in the rinds of fruits such as lemon, bergamot, etc. (*See* LEMON.) (3) *Extraction* by (*a*) volatile solvents such as petroleum ether, alcohol, etc. (a practice which has increased greatly of recent years); (*b*) by cold neutral fats (*"enfleurage"*) or (*c*) by hot oils or fats (*"maceration"*). Descriptions of these processes are given in the article PERFUMERY.

Terpeneless oils are prepared from several natural oils, *e.g.*, oil of lemon, by removal of the terpene hydrocarbons present by fractional distillation. These hydrocarbons have no odour value, and, on account of their liability to atmospheric oxidation, impair the keeping properties of the oil; further they diminish the solubility in dilute alcohol.

Synthetic Oils.—The so-called synthetic oils may be grouped into two classes: (1) *Isolates* or artificial oils, consisting of chemical individuals isolated in a more or less pure condition from a natural essential oil, *e.g.*, menthol, cineol, isolated by freezing from oils of peppermint and eucalyptus respectively; (2) oils synthesised by chemical means from such isolates (*e.g.*, piperonal from safrole of sassafras oil) or from other raw materials such as coal-tar derivatives (*e.g.*, methyl salicylate from salicylic acid). The synthetic essences may be identical with the odorous bodies present in a natural oil, for example, vanillin, synthesised from eugenol of oil of cloves, or from coal-tar guaiacol, and coumarin produced from salicylic aldehyde; many, however, are bodies which do not occur naturally in the plants. Such are ionone, derived from citral isolated from oil of lemongrass, which is the basis of all violet scents, and perhaps the most important of all the synthetic perfumes; nitrobenzene which although chemically distinct from the benzaldehyde of almond oil, nevertheless possesses a coarse almond odour, and the exceedingly interesting synthetic musks. These latter are structurally very different from the ketones isolated from natural musk which, however, they closely resemble in odour and fixative properties. (Further examples of synthetic perfumes are quoted in the article PERFUMERY.)

Applications.—Essential oils find an extensive range of uses, of which the principal are the various applications in perfumery (*q.v.*), for perfumes, toilet preparations, soaps, etc. Important also are the uses in connection with foods. The value of flavouring herbs, condiments, etc., is largely due to the ethereal oils contained in them, while the delicate aroma of tea, coffee, wine, etc., depends on the presence of minute quantities of the same bodies. Consequently essential oils, and in particular the terpeneless oils, are employed in the flavouring of aerated beverages, etc.; the synthetic fruit essences are largely used in confectionery.

Many of the volatile oils find extensive use in medicine, either on account of their disinfectant properties, *e.g.*, thymol, eucalyptol, borneol (the principal constituent of Borneo camphor, which, mentioned by Rhazes as early as A.D. 923, was used as a prophylactic for the plague in the Middle Ages), or for their analgesic value, *e.g.*, camphor, oil of wintergreen (treatment of rheumatism).

In the arts, oil of turpentine is used on the largest scale in the manufacture of paints and varnishes and as a source of artificial camphor. Oils of lavender and spike are used as paint vehicles, more especially for the painting of pottery and glass.

Production.—The cultivation of plants for ethereal oil production has become a large industry; the most important producing area for natural floral products is the Alpes Maritimes district in the south of France, but the industry is now extending to Germany and Italy and the countries bordering on the Mediterranean, such as Bulgaria, which has long been the centre for rose oil production. The increased consumption of synthetic perfumes has in many cases stimulated the agricultural side of the trade; enormous quantities of sassafras and lemongrass are now cultivated solely for the recovery of the respective isolates safrole and citral. Lavender and peppermint oils of English origin rank as the best qualities; Japan has practically a monopoly of menthol production, while from the Far East come also the spice oils, or their raw materials, such as cinnamon and cloves, with eucalyptus, camphor, etc. America imports the bulk of the essential oils required; her production, however, of peppermint, lemon and orange oils is rapidly increasing. Attempts are being made to develop the cultivation of essential oils of orange and lemon in Africa and Australia respectively. *See* also PERFUMES, TERPENES, LEMON, EUCALYPTUS, MUSK, etc.

ESSENTUKI, a town in the Terek county of the North Caucasian Area, U.S.S.R., in lat. 44° 2′ N., long. 42° 48′ E. It is 11 miles west by rail from Pyatigorsk, altitude 2,096 feet. In the last thirty years the population has increased from 9,974 to 23,218 (in 1926) and the town now has an electric station, and a factory for obtaining oil from sunflower seeds. Its alkaline and sulphur-alkaline mineral waters, similar to those of Ems, Selters and Vichy, are much visited in summer. The climate shows great variations in temperature.

ESSEQUIBO or **ESSEQUEBO,** one of the three counties of British Guiana, taking its name from the river Essequibo. (*See* GUIANA.)

ESSEX, EARLS OF. The first earl of Essex was probably Geoffrey de Mandeville (*q.v.*), who became earl about 1139, the earldom being subsequently held by his two sons, Geoffrey and William, until the death of the latter in 1189. In 1199 Geoffrey Fitzpeter or Fitzpiers (d. 1213), who was related to the Mandevilles through his wife Beatrice, became earl of Essex, and on the death of Geoffrey's son William in 1227 the earldom reverted for the second time to the Crown. Then the title to the earldom passed by marriage to the Bohuns, earls of Hereford, and before 1239 Humphrey de Bohun (d. 1275) had been recognized as earl of Essex. With the earldom of Hereford the earldom of Essex became extinct in 1373; afterwards it was held by Thomas of Woodstock, duke of Gloucester, a son of Edward III. and the husband of Eleanor de Bohun; and from Gloucester it passed to the Bourchiers, Henry Bourchier (d. 1483), who secured the earldom in 1461, being one of Gloucester's grandsons. The second and last

Bourchier earl was Henry's grandson Henry, who died early in 1540. A few weeks before his execution in 1540 Thomas Cromwell (*q.v.*) was created earl of Essex; then in 1543 William Parr, afterwards marquess of Northampton, obtained the earldom by right of his wife Anne, a daughter of the last Bourchier earl. Northampton lost the earldom when he was attainted in 1553; and afterwards it passed to the famous family of Devereux, Walter Devereux, who was created earl of Essex in 1572, being related to the Bourchiers. Robert, the third and last Devereux earl, died in 1646. In 1661 Arthur Capel was created earl of Essex, and the earldom is still held by his descendants.

ESSEX, ARTHUR CAPEL, 1st Earl of (1632–1683), English statesman, son of Arthur, 1st Baron Capel of Hadham (*c.* 1641), executed in 1649, and of Elizabeth, daughter and heir of Sir Charles Morrison of Cashiobury in Hertfordshire, was baptized on Jan. 28, 1632. In June 1648, then a sickly boy of 16, he was taken by Fairfax's soldiers from Hadham to Colchester, which his father was defending, and carried every day round the works with the hope of inducing Lord Capel to surrender the place. At the restoration he was created Viscount Malden and earl of Essex (April 20, 1661).

He early showed himself antagonistic to the court, to Roman Catholicism, and to the extension of the royal prerogative, and was coupled by Charles II. with Holles as "stiff and sullen men," who would not yield against their convictions to his solicitations. Nevertheless he was sent on an embassy to Denmark in 1669, and in 1672 became lord lieutenant of Ireland. During the five years of his rule in Ireland he took great pains to understand the Irish situation, the purity of his administration brought him into conflict with many interested persons, accustomed to corrupt methods, and he was recalled in 1677. On the fall of Danby in 1679 he became a commissioner of the treasury, and in the next year a member of the council. He was a supporter of the policy of Halifax, and in spite of his strong Protestant views, gained the king's confidence.

Subsequently his political attitude underwent a change, the exact cause of which is not clear—probably a growing conviction of the dangers threatened by a Roman Catholic sovereign of the character of James. He now, in 1680, joined Shaftesbury's party and supported the Exclusion bill, and on its rejection by the Lords carried a motion for an association to execute the scheme of expedients promoted by Halifax. On Jan. 25, 1681, at the head of fifteen peers he presented a petition to the king requesting the abandonment of the session of parliament at Oxford. He was a jealous prosecutor of the Roman Catholics in the popish plot, and voted for Stafford's attainder, on the other hand interceding for Archbishop Plunket, implicated in the pretended Irish plot. But he declined participation in Shaftesbury's design to seize the Tower in 1682, and on Shaftesbury's consequent departure from England became the leader of Monmouth's faction, in which were now included Lord Russell, Algernon Sidney, and Lord Howard of Escrick. Essex took no part in the wilder schemes of the party, but after the discovery of the Rye House Plot in June 1683, and the capture of the leaders, he was arrested at Cashiobury and imprisoned in the Tower. On July 30, he was discovered in his chamber with his throat cut. Evidence points clearly if not conclusively to suicide, his motive being possibly to prevent an attainder and preserve his estate for his family.

Essex was a statesman of strong and sincere patriotism, just and unselfish, conscientious and laborious in the fulfilment of public duties, blameless in his official and private life. Evelyn describes him as "a sober, wise, judicious and pondering person, not illiterate beyond the rule of most noblemen in this age, very well versed in English history and affairs, industrious, frugal, methodical and every way accomplished"; and declares he was much deplored, few believing he had ever harboured any seditious designs. He married Lady Elizabeth Percy, daughter of Algernon, 10th earl of Northumberland, by whom, besides a daughter, he had an only son Algernon (1670–1710), who succeeded him as 2nd earl of Essex.

Bibliography.—*See* the Lives in the *Dict. of Nat. Biography* and in *Biographia Britannica* (Kippis), with authorities there collected; Essex's Irish correspondence is in the *Stow Collection* in the British Museum, Nos. 200–217, and selections have been published in *Letters written by Arthur Capel, Earl of Essex* (1770) and in the *Essex Papers* (Camden Society, 1890), to which can now be added the *Calendars of State Papers, Domestic,* which contain a large number of his letters and which strongly support the opinion of his contemporaries concerning his unselfish patriotism and industry; *see* also *Somers Tracts* (1813), x., and for other pamphlets relating to his death the catalogue of the British Museum.

ESSEX, ROBERT DEVEREUX, 2nd[1] Earl of (1566–1601), son of the 1st Devereux earl, was born at Netherwood, Herefordshire, on Nov. 19, 1566. He was educated at Trinity college, Cambridge, and in 1585 accompanied his stepfather, the earl of Leicester, to Holland, where he distinguished himself at the battle of Zutphen. He now took his place at court, where he was in high favour with Elizabeth, and in consequence on bad terms with Raleigh. In 1587 he was appointed master of the horse, and in the following year was made general of the horse and installed knight of the Garter. On the death of Leicester he succeeded him as chief favourite of the queen. Elizabeth was approaching 60; Essex was scarcely 21. Though well aware of the advantages of his position, and somewhat vain of the queen's favour, his constant attendance on her at court was intolerable, and in 1589, without her consent, he joined the expédition of Drake and Sir John Norris against Spain. In June, however, he was compelled to obey a letter enjoining him at his "uttermost peril" to return immediately. In 1590 Essex married the widow of Sir Philip Sidney, but in dread of the queen kept the marriage secret. When it was avowed, the queen was excessively angry, but, on the understanding that the lady should "live retired in her mother's house," was mollified.

In 1591 Essex was appointed to the command of a force auxiliary to one formerly sent to assist Henry IV. of France against the Spaniards; after a fruitless campaign he was recalled from the command in Jan. 1592. For some years after this most of his time was spent at court, where he held a position of unexampled influence, both on account of the favour of the queen and from his own personal popularity. In 1596 he was appointed with Lord Howard of Effingham, Raleigh and Lord Thomas Howard, to the command of the successful expedition against Cadiz. Shortly after this the queen's feelings towards him seem to have changed, and an open rupture was only prevented by the influence of Francis Bacon, at that time Essex's most intimate friend. In 1597 he was appointed master of the ordnance, and in 1598 commander of an expedition against Spain, known as the Islands or Azores Voyage. As the Plate fleet escaped him he failed of his main purpose; and when on his return the queen met him with the usual reproaches, he retired to his home at Wanstead. Elizabeth conferred on Lord Howard of Effingham the earldom of Nottingham for services at Cadiz, the main merit of which was justly claimed by Essex, but she sought to console Essex by making him earl marshal of England. Nevertheless the quarrel remained unhealed. In a discussion on the appointment of a lord deputy to Ireland, Essex, on account of some taunting words of Elizabeth, turned his back upon her, and when she, unable to control her indignation, slapped him on the face, he left her swearing that such an insult he would not have endured even from Henry VIII.

In Aug. 1598, Essex succeeded Burghley as chancellor of Cambridge, and in the following year, while Ulster was in rebellion under the earl of Tyrone, was made lieutenant and governor-general of Ireland. His campaign was unsuccessful, and by opposing the commands of the queen and the council, agreeing with Tyrone on a truce in September, and suddenly leaving the post of duty with the object of privately vindicating himself before the queen, he laid himself open to serious charges. He was brought in June 1600 before a specially constituted court, deprived of his offices, and ordered to live a prisoner in his own house during the queen's pleasure. Chiefly through the intercession of Bacon his liberty was soon restored to him, but he was ordered not to return to court. When he was refused the renewal of his patent for sweet wines, he paraded (Feb. 7, 1601) the streets of

[1]*i.e.,* in the Devereux line.

London with 300 retainers, and shouted, "For the queen! a plot is laid for my life!" These proceedings awakened no response from the citizens, and Essex returned to Essex House, where after defending himself for a short time he surrendered. After a trial—in which Bacon, who prosecuted, delivered a speech against his quondam friend and benefactor, he was condemned to death, and notwithstanding many alterations in Elizabeth's mood, the sentence was carried out on Feb. 25, 1601.

Essex, who was lacking in the qualities necessary for a statesman or general, owed his position to his personal charm. He was brave, chivalrous, impulsive, imperious sometimes with his equals, but generous to all his dependants and incapable of secret malice. He was also a patron of literature and the drama, and himself a poet.

See W. B. Devereux, *Lives of the Earls of Essex* (1853); E. A. Abbott, *Bacon and Essex* (1877) and L. A. Cadwallader, *Career of the Earl of Essex* (1923); also the article BACON, FRANCIS, and authorities there, and general bibliography in *Camb. Mod. Hist.* (vol. 3, 1904); Lyton Strachey, *Elizabeth and Essex* (1928).

ESSEX, ROBERT DEVEREUX, 3RD[1] EARL OF (1591–1646), son of the preceding, was born in 1591. He was educated at Eton and at Merton college, Oxford. Shortly after the arrival of James I. in London, Essex (whose title was restored, and the attainder on his father removed, in 1604) was placed in the household of the prince of Wales to share his studies and amusements. At 15 he married Frances Howard, daughter of the earl of Suffolk; during his absence abroad (1607–09) she fell in love with Robert Carr (afterwards earl of Somerset), and on her charging her husband with physical incapacity, the marriage was annulled in 1613. A second marriage with Elizabeth, daughter of Sir William Paulet, also ended unhappily. From 1620 to 1623 he served in the wars of the Palatinate, and in 1625 he was vice-admiral of a fleet which made an unsuccessful attempt to capture Cadiz. In 1639 he was lieutenant-general of the army sent by Charles against the Scottish Covenanters, in what is known as the first Bishops' War, but there was no fighting. The outbreak of the Civil War in 1642, found him in command of the parliamentary army. At the battle of Edgehill he remained master of the field, and in 1643 he captured Reading, and relieved Gloucester; but in the campaign of the following year, on account of disease, financial disorders and his own lack of initiative, nearly his whole army fell into the hands of Charles. In 1645, on the passing of the self-denying ordinance, providing that no member of parliament should hold a public office, he resigned his commission; but his annuity of £10,000 was continued to him for life. He died on Sept. 14, 1646, his line becoming extinct.

See Robert Codrington, M.A., "Life of Robert Earl of Essex," printed in *Hart. Misc.;* Clarendon's *History of the Rebellion;* and Hon. W. B. Devereux, *Lives of the Earls of Essex* (1853).

ESSEX, WALTER DEVEREUX, 1ST[1] EARL OF (1541–1576), the eldest son of Sir Richard Devereux, was born in 1541. His grandfather was the 2nd Baron Ferrers, who was created Viscount Hereford in 1550 and by his mother was a nephew of Henry Bourchier, a former earl of Essex. Walter Devereux succeeded as 2nd Viscount Hereford in 1558, and in 1561 or 1562 married Lettice, daughter of Sir Francis Knollys. In 1569 he served as high marshal of the field, under the earl of Warwick and Lord Clinton, in the suppression of the northern insurrection. For his services he in 1572 received the Garter and was created earl of Essex, the title which formerly belonged to the Bourchier family. He offered on certain conditions to subdue and colonize, at his own expense, a portion of the Irish province of Ulster, at that time completely under the dominion of the rebel O'Neills, under Sir Brian MacPhelim and Tirlogh Luineach, with the Scots under their leader Sorley Boy MacDonnell. He set sail for Ireland in July 1573, but a storm dispersed his fleet, and his forces did not assemble till late in the autumn. His troops were diminished in winter quarters at Belfast to little more than 200 men. Intrigues of various sorts, and fighting of a guerrilla type followed, and Essex had difficulties both with the deputy Fitzwilliam and with the queen. His offensive movements in Ulster took the form of raids and brutal massacres among the O'Neills; in Oct. 1574 he treacherously captured MacPhelim at a conference in Belfast, and after slaughtering his attendants had him and his wife and brother executed at Dublin. Elizabeth, instigated apparently by Leicester, suddenly commanded him to "break off his enterprise"; but, as she left him a certain discretionary power, he took advantage of it to defeat Tirlogh Luineach, chastise Antrim, and massacre several hundreds of Sorley Boy's following, chiefly women and children, discovered hiding in the caves at Rathlin. He returned to England in the end of 1575. Elizabeth then made him earl marshal of Ireland, but he died of dysentery three weeks after his arrival in Dublin in the autumn of 1576. After his death Leicester married his widow. The massacres of the O'Neills and of the Scots of Rathlin leave a dark stain on the reputation of Essex.

[1] *i.e.*, in the Devereux line.

See Sidney Lee's article in the *Dict. Nat. Biog.; Lives of the Devereux Earls of Essex,* by Hon. Walter B. Devereux (1853); Froude's *History of England,* vol. x.; J. S. Brewer, *Athenaeum* (1870), part i. pp. 261, 326.

ESSEX, an eastern county of England, bounded north by Cambridgeshire and Suffolk, east by the North Sea, south by the Thames, dividing it from Kent, west by the administrative counties of London, Middlesex and Hertfordshire. Its area is 1,530 square miles. Its configuration is sufficiently indicated by the direction of its rivers. Except that in the northwest the county includes the heads of a few valleys draining northward to the Cam and so to the Great Ouse, all the streams run southward and eastward, either into the Thames, or into the North Sea by way of the broad, shallow estuaries which ramify through the flat coast lands. The highest ground lies consequently in the north-west, between the Cam basin and the rivers of the county. The Lea (which with its headwaters the Stort forms a great part of the western boundary), the Roding and several smaller streams flow southward to the Thames. Canvey island, just before Southend is reached, is typical of many of the marsh islands along the coast. Following the coast northward from Shoeburyness at the Thames mouth, the other chief rivers may be specified according to their estuaries. The Roach ramifies among several islands of which Foulness is the largest, while its main branch joins the estuary of the Crouch. Next follows the Blackwater, which receives the Chelmer, the Brain and other streams. Following the numerous creeks and islets, with the large island of Mersea, the Colne estuary is reached. The Colne and Blackwater may be said to form one large estuary, as they enter the sea by a well-marked common mouth, 5 m. in width, between Sales Point and Colne Point. There is a great irregular inlet (Hamford Water) receiving no large stream, west of the Naze promontory, and then the Stour, forming the boundary with Suffolk on the north, joins its estuary to that of the Orwell near the sea.

There are several popular seaside places along the Essex coast, of which Southend-on-Sea (with Leigh and Westcliff) above the mouth of the Thames, Clacton-on-Sea, Frinton-on-Sea, Walton-on-the-Naze, and Dovercourt adjoining Harwich are the chief. These and other stations on the estuaries, such as Burnham-on-Crouch, are also in favour with yachtsmen. The sea has at some points seriously encroached upon the land within historic times. The low soft cliffs at various points are liable to give way against the waves; in other parts dykes and embankments are necessary to prevent inundation. Inland the county is pleasantly undulating and for the most part well wooded. It was formerly, indeed, almost wholly forested, the ancient Waltham forest stretching from Colchester to the confines of London. Of this a fragment is preserved in Epping forest (*see* EPPING) between the Lea and the Roding. On the east of the Roding Hainault forest is traceable, but was disafforested in 1851. The oak is the principal tree; a noteworthy example was that of Fairlop in Hainault, which measured 45 ft. in girth, but was blown down in 1820.

Geology.—The geological structure of the county is very simple: the greater part is occupied by the London clay with underlying Reading beds and Thanet sands, with here and there small patches of Bagshot gravels on elevated tracts, as at High Beech, Langdon hill, Brentwood and Rayleigh; and occasionally the same beds are represented by the large boulder-like Sarsen

stones on the lower ground. In the north, the chalk, which underlies the Tertiary strata over the whole county, appears at the surface and forms the downs about Saffron Walden, Birdbrook and Great Yeldham; it is brought up again by a small disturbance at Grays Thurrock where it is quarried on a large scale for lime, cement and whiting. Small patches of Pleistocene Red Crag rest upon the Eocene strata at Beaumont and Oakley, and are very well exposed at Walton-on-the-Naze where they are very fossiliferous. Most of the county is covered by a superficial deposit of glacial drifts, sands, gravel and in places boulder clay, as at Epping, Dunmow and Hornchurch where the drift lies beneath the Thames gravel. An interesting feature in relation to the glacial drift is a deep trough in the Cam valley revealed by borings to be no less than 340 ft. deep at Newport; this ancient valley is filled with drift. In the southern part of the county are broad spreads of gravel and brick earth, formed by the Thames; these have been excavated for brick-making and building purposes about Ilford, Romford and Grays, and have yielded the remains of hippopotamus, rhinoceros and mammoth. More recent alluvial deposits are found in the valley at Walthamstow and Tilbury, in which the remains of the beaver have been discovered.

The roads of this county with a clay soil foundation were for generations repaired with flints picked by women and children from the surface of the fields. Gravel is difficult of access. With the exception of chalk for lime (mainly obtained at Ballingdon in the north and Grays in the south), septaria for making cement, and clay for bricks, the underground riches of the county are meagre.

INDUSTRIES AND COMMUNICATIONS

Agriculture and Industries.—As an agricultural county Essex ranks high, being one of the chief grain-producing counties. The wheat and barley are of high quality, the wheat being exported for seed purposes, while the barley is especially used in malting. Beans and peas are largely grown, as are vegetables for the London market. Hop-growing was once important. From the comparative dryness of the climate Essex does not excel in pasturage, and winter feeding receives the more attention.

The south-west of the county, being contiguous both to the river and to London, is the seat of large and varied industries, including food and chemical works, engine shops at Stratford, powder works in the vicinity of Waltham Abbey, and powder stores at Purfleet on the Thames. The extensive water-works for east London, by the Lea near Walthamstow, may also be mentioned. The docks at Plaistow and Tilbury on the Thames employ many hands. Apart from this industrial district, there are considerable engineering works, especially for agricultural implements, at Chelmsford, Colchester and elsewhere; silk works at Braintree and Halstead; large breweries at Brentwood, Chelmsford and Romford; and lime and cement works at Grays Thurrock (*see* section *Geology* above). The oyster-beds of the Colne produce the famous Colchester natives, and there are similar beds in the Crouch and Roach, for which Burnham-on-Crouch is the centre; and in the Blackwater (Maldon).

Railways.—Railway communications fall principally within the L.N.E.R. system, (1) the main line to Ipswich runs from south-west to north-east across the county by Stratford, Ilford, Romford, Brentwood, Chelmsford, Witham, Mark's Tey, Colchester and Manningtree. From this line various branches extend eastward to the sea: (a) at Shenfield (beyond Brentwood) via Billericay, Wickford and Rochford to Southend-on-Sea, with branches from Wickford returning via Maldon to the main line at Witham, and going east to Burnham and Southminster; (b) at Kelvedon (beyond Witham) to Tollesbury on the Blackwater; (c) Colchester going, via Wivenhoe, to Brightlingsea, and to Clacton, Frinton and Walton-on-the-Naze respectively. (2) The Cambridge line of the same company runs from south to north along the western border, entering the county across the Stort, which it follows to Bishop's Stortford, whence it strikes across the northwest corner of the county to Great Chesterford. This line throws out branches eastward: (a) from Bishop's Stortford (Herts.) via Dunmow and Braintree to the first line at Witham; (b) from Elsenham to Thaxted; (c) from Audley End via Saffron Walden and Haverhill, in a wide loop along the northern border through both Halstead (Colne Valley section) and Sudbury to Mark's Tey. (3) The angle between these two main lines is served by branch lines (a) to Chingford at the southern end of Epping Forest, (*b*) via Leyton, Woodford, Buckhurst Hill, Loughton and Epping to Chipping Ongar, while short interconnecting lines serve the populous districts nearer London, now also reached by the District railway to Barking. (4) The southern portion of the county from west to east along the Thames is served by the L.M.S.R. (Tilbury and Southend section) via (a) West Ham, Plaistow, East Ham, Barking and Upminster to Southend and Shoeburyness at the mouth of the Thames, together with (b) a southerly loop along the river by Purfleet, Grays and Tilbury, which rejoins the Southend line at Pitsea, while there is also a line joining Grays with Upminster and thence with the L.N.E.R. system at Romford.

On the Thames, besides the great docks at Plaistow and Silvertown (the Victoria and Albert and the King George V. docks) and the deep-water docks at Tilbury (*q.v.*) the principal calling places for vessels are Grays, Purfleet and Southend, while Barking on the Roding has also shipping trade, and the Lea affords important water-connections. Elsewhere, the principal port is Harwich, at the mouth of the Stour, an important port for passenger traffic to the Continent. Other towns ranking as lesser estuarine ports are: Brightlingsea and Wivenhoe on the Colne, forming a member of the Cinque Port of Sandwich; Colchester; Maldon on the Blackwater; and Burnham-on-Crouch. The Stour, Chelmer, and Lea and Stort are the principal navigable inland waterways.

Population and Administration.—The area of the administrative county, with its associated county boroughs, is 979,532 acres (of the former geographical county, 986,975 ac.); pop. (1921) 1,470,257, made up as follows: administrative county (municipal boroughs and urban and rural districts) 964,443 ac., pop. 920,141; county boroughs (West Ham, East Ham and Southend-on-Sea, *qq.v.*) 15,089 ac., pop. 550,116. Of this total the rural districts represent 862,361 ac. with a population of 273,814 (0·3 persons per acre), the greater part of the population being concentrated in the south-west corner adjoining London, where, as in Leyton and West Ham, densities of 100 to 135 persons per acre are reached.

The county is divided for parliamentary purposes into eight (county) divisions, each returning one member, namely; Epping, Saffron Walden, Harwich, Maldon, south-eastern Romford, Walthamstow and (in the centre) Chelmsford; while the following parliamentary boroughs also return one member in each constituency or division, namely, West Ham (four divisions), East Ham, Leyton and Walthamstow (two divisions each), and Ilford and Southend-on-Sea (one division each). There are seven municipal boroughs, with populations (1921) as follows: Chelmsford, 20,769; Colchester, 43,393; Harwich, 13,046; Maldon, 6,590; Saffron Walden, 5,874; Ilford (an urban district till 1926), 85,194; Leyton (like Ilford, created in 1926), 128,430. The urban districts are: Barking, 35,523; Braintree, 6,970; Brentwood, 6,853; Brightlingsea, 4,500; Buckhurst Hill, 5,008; Burnham-on-Crouch, 3,434; Chingford, 9,482; Clacton, 17,051; Epping, 4,196; Frinton-on-Sea, 3,032; Grays Thurrock, 17,359; Halstead, 5,923; Loughton, 5,749; Romford, 19,442; Shoeburyness, 6,413; Tilbury, 9,610; Waltham Holy Cross, 6,847; Walthamstow, 129,395; Walton-on-the-Naze, 3,664; Wanstead, 15,298; Witham, 3,717; Wivenhoe, 2,329; Woodford, 21,236. (In the figures for Clacton, Frinton and Walton, corrections of over 30% must be made, due to excess of summer visitors over the resident population.) Dagenham (9,127) was created an urban district in 1926 out of a former parish in Romford. The rural districts are: Belchamp, Billericay, Braintree, Bumpstead, Chelmsford, Dunmow, Epping, Halstead, Lexden and Winstree, Maldon, Ongar, Orsett, Rochford, Romford, Saffron Walden, Stansted, Tendring; of these Romford (29,485) alone exceeds 25,000.

Essex is in the south-eastern circuit, and assizes are held at the shire hall at Chelmsford. Colchester, Maldon, Saffron Walden

and West Ham have separate courts of Quarter Sessions, and Colchester and Southend-on-Sea have their own police. The southwest corner of the county falls within the area of the metropolitan police district of Greater London, which includes West and East Ham, Ilford, Leyton, the urban districts of Barking, Wanstead, Walthamstow, Dagenham, Buckhurst Hill, Chingford, Loughton, Waltham Holy Cross, Woodford, and the parish of Chigwell in Epping R.D., an area of over 60,000 ac. and about 900,000 population. The county is ecclesiastically within the diocese of Chelmsford and is divided into two archdeaconries. The county is included in the Eastern military command; Warley is a depot of the Essex regiment, and there is a garrison at Tilbury. At Shoeburyness there are a school of gunnery and an extensive ground for testing Government artillery of the largest calibre. The seaward limit of the Port of London authority on the Thames is a line drawn from Havengore Creek, 3 m. N.E. of Shoeburyness, to Warden Point on the opposite coast of Kent.

HISTORY AND ANTIQUITIES

History (*see* also below under Essex, Kingdom of).—Essex probably originated as a shire in the time of Aethelstan. According to the Domesday Survey it comprised 19 hundreds, corresponding very closely in extent and in name with those of the present day. Essex and Hertfordshire were under one sheriff until the time of Elizabeth. At the time of the Survey Count Eustace held a vast fief in Essex, and the court of the Honour of Boulogne was held at Witham. The stewardship of the forest of Essex was held by the earls of Oxford until they were deprived of it for adherence to the Lancastrian cause. In 1421 certain parts of Essex inherited by Henry V. from his mother were brought under the jurisdiction of the duchy of Lancaster.

Essex was part of the see of London from the time of the foundation of the bishopric in the 7th century. The archdeaconries are first mentioned in 1108; that of Essex extended over the south of the county; the north of the county was divided between the archdeaconries of Middlesex and Colchester. Colchester was constituted a suffragan bishopric by Henry VIII. In 1836 Essex was transferred to the diocese of Rochester, with the exception of nine parishes which remained in London. In 1845 the archdeacon of Middlesex ceased to exercise control in Essex. In 1875 Essex was transferred to the newly created diocese of St. Albans, and in 1914 to that of Chelmsford.

Owing to its proximity to the capital Essex was intimately associated with all the great historical struggles. The nobility of Essex took a leading part in the struggle for the charter, and of the 24 guardians of the charter, four were Essex barons. The castles of Pleshey, Colchester and Hedingham were held against the king in the Barons' War of the reign of Henry III., and 5,000 Essex men joined the peasant rising of 1381. During the Wars of the Roses the Lancastrian cause was supported by the de Veres, while the Bourchiers and Lord Fitz-Walter were among the Yorkist leaders. Several Essex men were concerned in the Gunpowder Plot, and in the Civil War of the 17th century the county rendered valuable aid to the parliament.

After the Conquest no Englishman retained estates in Essex of any importance, and the chief lay barons at the time of the Survey were Geoffrey de Mandeville and Aubrey de Vere. The de Veres, earls of Oxford, were continuously connected with the county until the extinction of the title two centuries ago. Pleshey was the stronghold of the Mandevilles, and, although the house became extinct in 1189, its descendants in the female line retained the title of earls of Essex. Essex has always been mainly an agricultural county, and the ordinary agricultural pursuits were carried on at the time of the Domesday Survey, which also mentions salt-making, wine-making, bee-culture and cheese-making, while the oyster fisheries have been famous from the earliest historic times. The woollen industry dates back to Saxon times, and for many centuries ranked as the most important industry. In the 16th century Colchester was noted for its cloth-weaving, and also possessed a valuable leather industry, at which period Essex was considered an exceptionally wealthy and prosperous county; Norden, writing in 1594, describes it as "moste fatt, frutefull, and full of all profitable things."

The county returned four members to parliament in 1290. From 1295 it returned two members for the county and two for Colchester. Maldon acquired representation in 1331 and Harwich in 1604. Under the Reform Act of 1832 the county returned four members in four divisions until 1868 when it returned six members in three divisions.

Antiquities.—Ashingdon church tower, believed to have been erected by Canute after his victory over Edmund Ironside, shows recognizable traces of Saxon masonry. But the comparative scarcity of stone and the unusual abundance of timber led to the extensive employment of the latter material and consequent later destruction. Several of the Essex churches, as Blackmore, Mountnessing, Margaretting and South Benedict, have massive porches and towers of timber; and St. Andrew's church, Greenstead, with its walls of solid oak, continues an almost unique example of its kind. Of the four round churches in England one is in Essex at Little Maplestead; it is both the smallest and the latest. The churches of South Weald, Hadleigh, Blackmore, Heybridge and Hadstock may be mentioned as containing Norman work; the church of Castle Hedingham for its fine Transitional work; Southchurch, Danbury and Boreham as being partly Early English; Ingatestone, Stebbing and Tilty for specimens of Decorated architecture; and Messing, Thaxted, Saffron Walden, and the church of St. Peter ad Vincula at Coggeshall, near Colchester, as specimens of Perpendicular. The finest remains of stained glass windows are those of Margaretting. A remarkable series of paintings, probably of the 12th century, but much restored in the 14th, exists in the chancel of Copford church; and in the church at Ingatestone there was discovered in 1868 an almost unique fresco representation of the seven deadly sins. Fourteenth century brasses are preserved at Pebmarsh, Corringham, Aveley, Little Horkesley and at South Ockendon (1400); and ancient wooden effigies at Danbury, Little Leighs and Little Horkesley.

Essex was rich in monastic foundations, though the greater number have left but meagre ruins behind. The Benedictines had an abbey at Saffron Walden, nunneries at Barking and Wickes, and priories at Earl's or Monk's Colne and Castle Hedingham; the Augustinian canons had an abbey at Waltham (*see* Waltham Abbey) and priories at Thoby, Blackmore, Bicknacre, Little Leighs, Little Dunmow and St. Osyth (*see* Brightlingsea); there were Cistercian abbeys at Coggeshall, Stratford and Tilty; the Cluniac monks were settled at Prittlewell, the Premonstratensians at Beleigh Abbey, and the Knights Hospitallers at Little Maplestead. Barking Abbey is said to date its first origin from the 7th century; most of the others arose in the 12th and 13th centuries. Besides the keep at Colchester there is a fine Norman castle at Castle Hedingham. Havering-atte-Bower, a palace that was occupied by many queens, is replaced by a modern house. New Hall, which was successively occupied by Henry VIII., Elizabeth, the earl of Essex, George Villiers, duke of Buckingham, and Cromwell, still stands. Audley End is a noble example of the domestic architecture of the Jacobean period; Layer Marney shows Italian influences in the time of Wolsey. Horeham Hall was built in the reign of Henry VII., and Gosfield Hall is of about the same date.

ESSEX, KINGDOM OF, an early English kingdom, of whose origin and early history we have no record except the statement of Bede that its settlers were of the Old Saxon race. In connection with this it is interesting to notice that the East Saxon dynasty claimed descent from Seaxneat, not Woden. The form Seaxneat is identical with Saxnot, one of three gods mentioned in a short continental document probably of Old Saxon origin. Bede does not mention this kingdom in his narrative until 604, the year of the consecration of Mellitus to the see of London. The boundaries of Essex were in later times the rivers Stour and Thames, but the original limits of the kingdom are uncertain; towards the west it probably included most of Hertfordshire, and in the 7th century the whole of Middlesex. In 604 we find Essex in close dependence upon Kent, being ruled by Sabert, sister's son of Aethelbert, under whom the East Saxons received Christianity. The three sons of Sabert, however, expelled Mellitus from his see, and even after their death in battle against the West Saxons, Eadbald of Kent was unable to restore him. In 653 we find Northumbrian influence paramount in Essex, for King Sigebert at the instance of Oswio became a Christian and received Cedd, the brother of St. Chad, as bishop, Tilbury and *Ythanceastere* (on the Blackwater) being the chief scenes of his work. Swithhelm, the successor of Sigebert, was on terms of friendship with the East Anglian royal house, King Aethelwald being his sponsor at his baptism by Cedd. It was probably about this time that Erconwald, afterwards bishop of London, founded the monastery of Barking. Swithhelm's successors Sigehere and Sebbe were dependent on Wulfhere, the powerful king of Mercia, who on the apostasy of Sigehere sent Bishop Jaruman to restore the faith. There are grounds for believing that an East Saxon conquest of Kent took place in this reign. A forged grant of Ceadwalla speaks of the fall of Kent before Sigehere as a well-known event; and in a Kentish charter dated 676 a king of Kent called Swebhard grants land with the consent of his father King Sebbe. In 692 or 694 Sebbe abdicated and received the monastic vows from Waldhere, the successor of Erconwald at London. His sons Sigeheard and Swefred succeeded him as kings of Essex, Sigehere being apparently dead. As the laws of Ine of Wessex speak of Erconwald as "my bishop," it is possible that the influence of Wessex for a short time prevailed in Essex; but a subsequent charter of Swefred is approved by Coenred of Mercia, and Offa, the son of Sigehere, accompanied the same king to Rome in 709. From this time onwards the history of Essex is almost a blank. In 743 or 745 Aethelbald of Mercia is found granting privileges at the port of London, and perhaps the western portion of the kingdom had already been annexed, for henceforward London is frequently the meeting-place of the Mercian council. The violent death of Selred, king of Essex, is mentioned in the *Saxon Chronicle* under the year 746; but we have no more information of historical importance until the defeat of the Mercian king Beornwulf in 825, when Essex together with Kent, Sussex and Surrey, passed into the hands of Egbert, king of Wessex. After 825 we hear of no more kings of Essex, but occasionally of earls. About 870 Essex passed into the hands of the Danes and was left to them by the treaty between Alfred and Guthrum. It was reconquered by Edward the Elder. The earldom in the 10th century apparently included several other counties, and its most famous holder was the ealdorman Brihtnoth, who fell at the battle of Maldon in 991.

The following is a list of kings of Essex of whom there is record: Sabert (d. *c.* 617); three sons of Sabert, including probably Saweard and Seaxred; Sigebert (Parvus); Sigebert II.; Swithhelm (d. *c.* 664); Sigehere (reigned perhaps 664–689); Sebbe, son of Seaxred (664–694); Sigeheard (reigning in 693–694); Swefred (reigning in 693–694 and in 704); the two last being sons of Sebbe; Swebriht (d. 738); Selred (d. 746); Swithred, grandson of Sigeheard (succ. 746); Sigeric, son of Selered (abd. 798); Sigered, son of Sigeric (reigning in 823).

ESSEX INSTITUTE, THE, an American institution at Salem, Mass., founded for the promotion of the study of history, science and art in Essex county, was formed in 1848 by the union of the Essex Historical Society and the Essex County National History Society. It is supported by an annual assessment upon its members and by the income from its funds. Its museum contains one of the largest American collections of historical objects illustrating the life of the English settler, including type-rooms, costumes, furniture, china, glass, war relics, tools, medals and coins. Its numerous portraits include examples by Stuart, Blackburn, Smibert, Trumbull, Greenwood, Frothingham, Vinton, Osgood and others. The library contains over 500,000 volumes, among which are several specialized collections, such as Essex county imprints, China and the Chinese (over 4,000 vol.), commercial, marine, directories and newspapers. In the rear garden is a fine specimen of a 1684 dwelling, furnished in the period.

ESSLINGEN, a town of Germany, in the republic of Württemberg, in a fertile district on the Neckar, 9 m. S.E. from Stuttgart, on the railway to Ulm. Pop. (1925) 40,562. Esslingen, which dates from the 8th century, became a town in 886. It became a free imperial city in 1209 and was surrounded with walls by order of the emperor Frederick II. Its liberty was frequently threatened by the rulers of Württemberg, but it did not become part of that country until 1802. It is surrounded by mediaeval walls with towers and bastions, and has numerous suburbs. On a commanding height above the town lies the old citadel. The inner town has an old (1430) and a new Rathaus, formerly a palace. The church of Our Lady (Frauenkirche) is a fine Gothic building of the 15th century with a beautifully sculptured doorway and a lattice spire 240 ft. high. The church of St. Dionysius, dating from the 13th century, possesses a fine screen and a ciborium of 1486. The municipal archives at Esslingen contain much valuable literature bearing especially on the period of the Reformation. The town has railway, machine and electrical works; cloth, gloves and metal goods are also manufactured here, and there are spinning-mills. Famous for its wines, and possessing the oldest sparkling wine cellarage in Germany. Esslingen does a considerable trade in wine and fruit.

ESTABLISHMENT, a word applied to certain religious bodies in their relation to the State.

Perhaps the best definition which can be given, and which will cover all cases, is that establishment implies the existence of some definite and distinctive relation between the State and a religious society (or conceivably more than one) other than that which is shared in by other societies of the same general character. It denotes any special connection with the State, or privileges and responsibilities before the law, possessed by one religious society to the exclusion of others; in a word, establishment is of the nature of a monopoly.

But it does not imply merely privilege. The State and the Church have mutual obligations towards one another: each is, to some extent, tied by the existence of this relationship, and each accepts the limitations for the sake of the advantages which accrue to itself. The State does so in view of what it believes to be the good of all its members; for "the true end for which religion is established is not to provide for the true faith, but for civil utility" (Warburton), even if the latter be held to be implied in the former. On the other hand, the Church accepts these relations for the facilities which they involve, *i.e.*, for its own benefit.

It will be seen that this definition excludes, and rightly, many current presuppositions. Establishment affirms the *fact*, but does not determine the precise *nature*, of the connection between the State and the religious society. It does not tell us, for example, when or how it began, whether it is the result of an unconscious growth (as with the Gallican Church previous to the French Revolution), or of a determinate legislative act (as with the same Church re-established by the Concordat of 1801). It does not tell us whether an endowment of the religious society by the State is included; what particular privileges are enjoyed by the religious society; and what limitations are placed upon the free exercise of its life. These things can be ascertained only by actual

inquiry; for the conditions are precisely similar in no two cases.

Of the sovereign States existent in 1928 about two-thirds were without establishments, among them the United States, France, Germany, Poland, Hungary and Japan. But among the nations having no State religion some give support to ecclesiastical organizations. Thus, in the Argentine Republic the Roman Catholic Church is State-supported, and in the Netherlands the Protestant, Roman Catholic, Jansenist and Jewish churches receive financial assistance from the Government. In Belgium the ministers of all religious congregations are assisted by the national treasury. Besides England, the nations supporting establishments include Spain, Sweden, Italy, Bulgaria, Greece, Finland, Bolivia and Peru. Of the total number of such countries about one-half are monarchies and one-half republics, while in the States without establishments the proportion is, respectively, about one-third and two-thirds.

Church of England.—The word Establishment as applied to the Church of England denotes the existence of a special relationship between Church and State without defining its exact nature. The statement that this Church is "established by law" denotes that it has a peculiar status before the law; but this is all. It cannot be said that it was established at any particular time, or by any particular legislative act. There were no doubt periods when the existing relations between Church and State were modified or re-defined, notably in the 16th and 17th centuries; but the relations themselves are far older. They existed from the first; the English Church and State grew up side by side, and from the very beginning they were in close relations with one another. But although the state of things which it represented was there from the first, the term "established," or "established by law," came into use only at a later date. Until there was some other religious society to be compared with it, such a distinctive epithet would have had no point.

The questions which arise out of the relations between Church and State are difficult and their difficulties are increased by the imperfections and ambiguities of language; which lead us to forget that *Church* and *State* are abstract terms; that the concrete reality underlying each is an aggregate of individuals knit together by an ideal bond; and that the same persons who from one point of view constitute the State constitute the Church also, the Church being the nation on its religious side. The theory of a Church Establishment rests historically on the assumption that, this being so, it is the right and duty of a Christian State to exert its influence for the maintenance and propagation of religion. But the case is materially changed when the unity of Christian belief has been split up into a multitude of conflicting sects. The application of the general principle to such a state of things is then beset with grave difficulties both of theory and in practice.

Religious Establishments have been defended and attacked on grounds of principle. Their authority is, in fact, founded on utility; and is to be argued, not as a matter of right or wrong, but on certain broad lines of moral and political science which we are left to discover and apply by the light of our own reason and conscience. Their application will vary with circumstances. Man is the measure of all things, or, in the language of religion, "the Sabbath was made for man." This is particularly the case when questions of property are involved. Should circumstances lead to a separation between Church and State, what is to be held with regard to the property which has previously been enjoyed by the former either by the gift of the State or under the sanction of the law? It requires some hardihood to argue that its secularization is, as such, unlawful; or to deny that the title of the Church to its possession is less subject than that of secular corporations to the *altum dominium* of the State.

The *locus classicus* on the question as a whole is the chapter in Paley's *Principles of Moral and Political Philosophy*, "Of Religious Establishments and of Toleration." The conclusion arrived at is, "That a comprehensive national religion, guarded by a few articles of peace and conformity; together with a legal provision for the clergy of that religion; and with a *complete* toleration of all dissenters from the Established Church, without any other limitation or exception than what arises from the conjunction of dangerous political dispositions with certain religious tenets—appears to be, not only the most just and liberal, but the wisest system which a state can adopt: inasmuch as it unites the several perfections which a religious constitution ought to aim at—liberty of conscience, with means of instruction; the progress of truth, with the peace of society; the right of private judgment, with the care of the public safety."

The Concordat.—In mixed countries like England, a Church Establishment, which has in itself the nature of privilege, is unlikely either to be introduced, or, if it has been abolished, to be restored. Where it exists and works for the greater good of the greater number, it may reasonably be retained. Should it, however, become a source of inconvenience or discord, its sufficient reason would disappear. Were the Dissenters to be in a majority, the Establishment itself should be revised and qualified, Paley thinks; were there a certain parity of sects, he suggests a scheme of concurrent endowment. In England many of the reforms which he desired have now been introduced; and the judgments of the Courts of Appeal have been uniformly in the direction of inclusion: the less we define, it has been recognised, the better: "Vitals in religion are few." It is the tendency of the larger Churches to develop on the lines of a Concordat, on the one hand between religion and secular thought, and on the other between conflicting Church parties. In an age when the clerical and the lay minds are diverging more and more widely, and the fissiparous tendencies of religious parties appear to be on the increase, it is difficult to see how the coherence of the body corporate can be retained. Whether this difficulty can, or cannot, be overcome is the religious, perhaps not only the religious, problem of our time.

Disestablishment is in theory the annulling of establishment; but since an established Church is usually rich, disestablishment generally includes disendowment, even where there is no state endowment of religion. It is, in short, the abrogation of establishment, coupled with such a confiscation of Church property as the State thinks good in the interests of the community.

ESTABLISHMENT OF A PORT, the technical expression for the time that elapses between the moon's transit across the meridian at new or full moon at a given place and the time of highwater at that place. The interval (constant at any one place) may vary from 6 mins. (Harwich) to 11 hrs. 45 mins. (North Foreland). At London Bridge it is 1 hr. 58 mins. (*See* Tide.)

ESTAING, CHARLES HECTOR, Comte d' (1729–1794), French admiral, was born at the château of Ruvel, Auvergne. In 1757 he accompanied count de Lally to the East Indies, with the rank of brigadier-general. In 1759 he was made prisoner at the siege of Madras, but was released on parole. On his return to France in 1760 he fell into the hands of the English and, on the ground of having broken his parole, was thrown into prison at Portsmouth, but soon released. In 1778 he obtained the command of a fleet intended to assist the United States against Great Britain. He sailed on April 13, and between July 11 and 22 blockaded Howe at Sandy Hook. In concert with the American generals, he planned an attack on Newport; but before the concerted attack could take place, he put to sea against the English fleet,

under Lord Howe. A storm shattered his fleet, and he had to put into Boston for repairs. He then sailed for the West Indies on Nov. 4 where he captured St. Vincent and Grenada. On July 6, 1779 he fought a drawn battle with Admiral John Byron, who retired to St. Christopher. Though superior in force, D'Estaing would not attack the English in the roadstead, but set sail to attack Savannah. All his attempts were repulsed with heavy loss. He returned to France in 1780. He was in command of the combined fleet before Cadiz when the peace was signed in 1783. In 1787 he was elected to the assembly of the notables; in 1789 he was appointed commandant of the national guard; and in 1792 he was chosen admiral by the National Assembly. On the trial of Marie Antoinette in 1793 he bore testimony in her favour. He was himself brought to trial, and was executed on April 28, 1794.

ESTATE, the state or condition in which a man lives, now chiefly used poetically and in such phrases as "man's estate," or "of high estate"; "state" has superseded most of the uses of the word except (1) in property, and (2) in constitutional law.

1. In the law of property the word is employed in several senses. In the widest sense a man's estate comprises his entire belongings; so much of it as consists of land and certain other interests associated therewith is his "real estate"; the rest is his "personal estate." The word is more particularly applied to interests in land, and in popular and general use "an estate" means the land itself. The strict technical meaning at common law of "an estate" was a freehold in lands. "The first thing that the student has to do," says Joshua Williams (*Law of Real Property*), "is to get rid of the idea of absolute ownership. Such an idea is quite unknown to the English law. No man is in law the absolute owner of lands. He can only hold an estate in them." That is, the notion of tenure, of holding by a tenant from a lord, prevails. The last lord of all from whom all land was ultimately held was the king. Persons holding directly from the king and granting to others were the king's tenants *in capite*, and were the mesne lords of their tenants.

Legal estates in land were of three kinds: (1) Fees simple, under which the land on the death of the owner intestate descended to his common law heir, and if he had no such heir escheated to the lord of whom it was held, who claimed on the ground that though he had no estate in the land himself, yet as the lord of whom it was held, he was entitled to it on the failure of the estate granted to the tenant in fee simple; (2) fees tail, under which the land, on the death of the tenant in tail, descended to the heir of his body, whether he died intestate or not, and if he left no heir of the body the land reverted to the grantor who after granting the fee tail still was the owner in fee simple, in remainder of the land; (3) life estate, which were of two kinds, estates for the life of the tenant and estates for the life or lives of some other person or persons (called estates *pur autre vie*). The chief distinction was that an estate *pur autre vie* might survive the tenant, and then, unless it was limited to him and his heir, the land became ownerless till someone took possession of it (called the "general occupant").

All this has now, so far as England is concerned, been abolished by The Law of Property Act. Now, the only legal estate that can subsist in land is fee simple, and it is practically absolute ownership since escheat and the other incidents of tenure including kinship are abolished. Fee tail and life estates can subsist only as equitable interests, so equitable fee tail may be disposed of by the will of the tenant in tail.

Interests in land not of freehold were not regarded at common law as any part of the ownership, but merely as hirings of the land. They were divided into (i.) interests, a time certain (often called terms, the instruments creating them being termed leases or demises, and the interests leaseholds); (ii.) tenancies at will, that is, where lands or tenements are let by one man to another to have and to hold at the will of the lessor; (iii.) tenancies at sufferance, where one comes into possession of land under a lawful title, and continues in possession after his title has determined.

Under the Law of Property Act, 1925, absolute terms are the only legal interests besides fees simple which can now subsist in lands. Accordingly the old common law as to personalty, which permitted only absolute ownership and hiring of goods, now applies to land.

(2) In constitutional law an estate is an order or class having a definite share as such in the body politic, and participating either directly or by its representatives in the Government. The system of representation by estates took its rise in western Europe during the 13th century, at a time when the feudal system was being broken up through various causes, notably the growing wealth and power of the towns. In the feudal council the clergy and the territorial nobles had alone had a voice; but the 13th century, to quote Stubbs, "turns the feudal council into an assembly of estates, and draws the constitution of the third estate from the ancient local machinery which it concentrates." This is, allowing for differences of detail, true of other countries as well as England. To the two estates already existing, clergy and nobles, is added a third, that of the commons (burgesses and knights of the shire) in England, that of the *roturiers* in France (known as the *tiers état*).

The system of estates, based on the mediaeval conception of society as divided into definite orders, formed the basis of whatever constitutional forms survived in Europe till the French Revolution. In England, of course, it had early become obscured, the House of Commons representing the whole nation outside the narrow order of the peers. The phrase "three estates," as applied to the English Constitution at present, is misleading. It is now usually understood of the lords spiritual, the lords temporal and the commons.

In the constitutional struggles of the European continent, from the Revolution onward, the rival theories of representation by estates and of popular representation have played a great part. The crucial moment of the French Revolution was when the vote according to "order" was rejected, and the estates of the clergy and nobles were merged with the *tiers état*, the States-General thus becoming the National Assembly. This was the precedent followed, generally speaking, during the 19th century in the other countries in which constitutional government was established.

The plural form ESTATES or STATES was the name commonly given to an assembly of estates. When such an assembly was not merely local or provincial it was called the Estates-General or States General, *e.g.*, in France the assembly of the deputies of the three estates of the realm as distinct from the provincial estates, which met periodically in the so-called *pays d'états*. (*See* also REPRESENTATION.)

For further details about the estates in England and elsewhere *see* W. Stubbs, *Constitutional History*; vol. ii. (1896); H. Hallam, *The Middle Ages* (1855); F. W. Maitland, *Constitutional History of England* (1908); A. Luchaire, *Histoire des institutions monarchiques de la France* (1883–85); G. Waitz, *Deutsche Verfassungsgeschichte* (Kiel, 1865–78); and A. S. Rait, *The Scottish Parliament* (1901).

United States.—Generally speaking, the common law system of estates prevails in America. With the Revolution the various States succeeded to the rights of king as overlord with the result that the owner of an estate in fee simple holds directly of the State. If he died without heirs the land escheats to the State. In a few States, by statute or judicial decision land is not held of the State but the system of allodial ownership prevails. The differences, however, are not marked inasmuch as the State also succeeds to the allodial owner should he die without heirs.

The estate tail also exists in the United States. In many States it has been abolished by statute, such statutes operating either to give the donee in tail an estate in fee simple or an estate for life. In Iowa, the estate tail was abolished by judicial decision, the existence of such an estate in land being regarded as inimical to the spirit, genius and institutions of America. Some States by interpreting legislation as impliedly repealing the old English statute of *De Donis* have thereby abolished the estate tail. The old English devices of common recoveries and fines that enabled a tenant in tail to transform his estate into a fee simple were recognized in America. Statutes in practically all

States now enable the tenant in tail to accomplish this result with greater ease, a properly recorded conveyance by him being deemed sufficient.

The common law life estate has survived with little change. In dealing with estates *pur autre vie*, statutes have generally abolished the common law doctrine of the common occupant and made specific provisions for the disposition of the residue where the tenant dies and under the old view the land becomes ownerless.

ESTATE AND HOUSE AGENTS. A person exercising the calling of a house agent in England is required, under a penalty, to take out yearly a licence upon which is charged excise duty, unless he is licensed as an auctioneer or appraiser, or is an agent employed in the management of landed estates, or a solicitor or conveyancer who has taken out his annual certificate as such. In this connection a person is deemed to be a house agent if he advertises for sale or for letting, or in any way negotiates for the selling or letting of any furnished house or part of any furnished house (any storey or flat rated and let as a separate tenement being for this purpose a house); subject, however, to the qualification that no one is to be deemed to be a house agent by reason of his letting, or offering to let, or in any way negotiating for the letting of, any house the annual rent or value of which does not exceed £25.

His business is to endeavour to find a person willing to become a purchaser or tenant and then to communicate his offer to the owner. Unless express authority is given to the agent to sell or let, and for that purpose to enter into a binding contract, the principal reserves his right to accept or refuse the offer. As a rule, a house or estate agent has no authority to receive payment on behalf of the principal. Where he is employed to procure a tenant, he must use reasonable diligence to ascertain that the person to whom the property is let through his agency is fit to be a tenant. He does not, however, in any way guarantee the payment of the rent. A house agent may not, for or in expectation of payment, prepare any deed relating to the sale or letting of real or personal estate. There is, however, no similar prohibition as to agreements not under seal.

House agents are usually remunerated by way of commission. The scale adopted by the Institute of Estate and House Agents embodies the rates usually charged. In the absence of express provision upon the subject between the principal and the agent, commission is payable when the latter has found a purchaser or tenant willing to buy or take property upon the terms upon which the principal intimated to him his willingness to sell or let it.

Most auctioneers, in addition to holding auctions, carry on the business of house and estate agency. (*See* AUCTION; PRINCIPAL AND AGENT; VALUATION.)

ESTATE DUTIES. From early times the occasion of death has provided a convenient opportunity for the sovereign or the state to participate in the reckoning which necessarily follows a man's death. The casualties incident to feudal tenure were in effect taxes on successions to property levied by the sovereigns of England through the "*inquisitio post mortem.*" The court of wards and liveries established by Henry VIII. regulated these enquiries until its abolition in the reign of Charles II. Death duties as such first appeared upon grants of probate and administration, being copied from Holland in June, 1694, during the reign of William and Mary. Imposed first at a low rate of only 5s. for each probate for property above £20 in value, the duties between 1779 and 1797 were charged on an ascending scale. Under the influence of the Napoleonic Wars the rates were further increased and the graduation extended up to estates of the value of £1,000,000 sterling. In 1804 a probate duty similar to that in force in England was imposed in Scotland. Another succession tax was first imposed in Great Britain in 1780, when stamps were required on receipts for legacy. When it was discovered that by the absence of a receipt the duty would be avoided a further act was passed in 1796 by which the duty was imposed upon the legacy. The act was confined to legacies of personal estate—a bill proposed by Pitt for similar duties on legacies charged upon and devises of real estate having been withdrawn. This legacy duty distinguished the recipients of legacies according to the nearness or remoteness of their relationship with their benefactor. At the beginning the lowest rate was 2% for brothers and sisters and their descendants and the highest rate was 6% for strangers in blood.

In 1805 the charge of legacy duty was extended to testamentary gifts of the proceeds of sales of real property but it was not until 1853, by the Succession Duty Act of that year, that (under the name of succession duty) a death duty corresponding in principle to the legacy duty was thrown on acquisitions of two main categories of property which had previously escaped the charge of a death duty. These consisted of personal property which was not previously liable to legacy duty, composed mainly of settled movable property, and real property. After the introduction of the new duty, leasehold property devolving under a will or intestacy was charged therewith instead of with legacy duty, and in 1888 succession duty replaced the legacy duty which since 1805, as already noted, had been charged on testamentary gifts of the proceeds of sale of real property.

Another succession duty, known as account duty, was imposed in 1881 and partook of the nature of a preventive of the evasion of probable duty rather than of a new tax. It was confined to personal or movable property and imposed upon such descriptions of property as property taken as *donatio mortis causa*, and property passing under any voluntary settlement by deed or any other instrument not taking effect as a will, whereby an interest in the property for any period determinable by death was reserved to the settlor. Temporary estate duty was introduced in 1889 at the rate of 1% on all personal property exceeding the value of £10,000 passing by will or intestacy or included in "Account" and also on successions exceeding the value of £10,000. This tax was levied in addition to the probate and legacy or succession duties.

In 1894 the littered state of this part of the field of taxation was partially cleared up by the imposition of the estate duty and the sweeping away of the probate duty (which in Scotland had come to be called inventory duty), account duty and temporary estate duty. These taxes, however, remained leviable in connection with deaths which occurred during specified periods, the last of which did not expire until May 12, 1914. Three duties are left, which fall into two classes. The first class is represented by the estate duty—a duty payable with reference to the acquisition of property on death; the second class comprises the old legacy duty and succession duty, each of which, as already stated, is a duty payable with reference to the acquisition of property by beneficiaries. Details of the present legacy duty and succession duty are given under the head of LEGACY DUTY.

The British Estate Duty.—1. The estate duty was imposed by the Finance Act, 1894, but the provisions of that act have been varied from time to time by amendments contained in subsequent finance and other acts. Speaking broadly, estate duty is an *ad valorem* graduated tax leviable upon the principal value of all property situate in Great Britain (whether immovable or movable, settled or not settled), which passes upon the death, after Aug. 1, 1894, of any individual; the liability in respect of such property attaches without reference either to the domicile of the deceased or to the distribution of the property among the beneficiaries, or to the method by which such distribution is regulated.

2. Property so passing includes the following:—

(a) Property of which the deceased was at the time of death competent to dispose (*e.g.*, by the exercise of a general power of appointment), whether actually disposed of or not.

(b) Gifts made by the deceased during illness, in contemplation, and intended only to become absolute in case of death (*donationes mortis causâ*).

(c) Gifts made by the deceased *inter vivos* without reservation within three years preceding death (excluding, however, gifts made for public or charitable purposes more than 12 months before his death; gifts made in consideration of marriage; reasonable gifts proved to have been part of his normal expenditure; and gifts not exceeding £100 in value in case of any donee).

(d) Gifts made by the deceased *inter vivos*, at any time, if

bona fide possession of the gift was not immediately assumed and thenceforth retained by the donee to the entire and irrevocable exclusion of the donor.

(e) Property which the deceased had voluntarily transferred from his own absolute ownership to the joint ownership of himself and some other person so that some beneficial interest therein passed by survivorship on his death to such other person.

(f) Moneys receivable under policies of insurance on the life of the deceased, effected and kept up by him wholly or partially for the benefit of a donee.

(g) Any annuity (subject to minor exceptions) or other interest, which the deceased provided, either alone or with some other person, to the extent of the beneficial interest arising by survivorship on his death.

(h) Property in which the deceased, or any other person, had an interest ceasing on the death of the deceased, to the extent to which a benefit arises by the termination of that interest.

(i) Property passing under any instrument executed by the deceased (not taking effect as a will) under which he reserved an interest, or any right to resume his interest, in the property.

3. Immovable property situate out of Great Britain, devolving as such, is not liable to estate duty in any circumstances.

4. Movable property situate out of Great Britain is, speaking generally, only chargeable with estate duty either (i.) when the deceased was the owner and was domiciled in some part of Great Britain; or (ii.) when the deceased was only interested for life, and at his death the property formed the subject of a British trust or was vested in a British trustee.

5. Immovable property means lands and houses and all interests therein, including leasehold interests; movable property includes all other property, whether tangible (such as goods, furniture, etc., having a physical situation), or intangible (such as stocks, shares, securities, etc., which, in strictness, consisting only of rights, have no physical situation).

Rates of Estate Duty.—6. Estate duty is charged at an *ad valorem* rate on the net principal value of the estate in accordance with the rates shown in the table in next column.

Provision is made for two fixed duties in the case of estates not exceeding a gross value of (*a*) £300, and (*b*) £500, viz., 30s. and 50s. respectively. The net principal value of the estate is represented by the aggregation of the principal values of all the items of property, less deductions for reasonable funeral expenses, and, subject to certain restrictions, for debts and incumbrances incurred or created by the deceased *bona fide* for full consideration. The principal value of any property is defined to be the price which, in the opinion of the commissioners of inland revenue, the property would fetch if sold in the open market at the time of the death of the deceased. The rule of aggregation for determination of the net principal value subject to duty is, however, subject to certain complex exceptions.

7. The statutes provide for exemptions of certain property from estate duty, among which may be mentioned (*a*) the exemption of estates of a total net principal value not exceeding £100; (*b*) the exemption of the property of common seamen, marines, soldiers or airmen who are slain or die in His Majesty's service; (*c*) the exemption, or partial exemption (i.) of the property passing on the death of certain persons killed in war, (ii.) of certain pensions granted by the Government of British India, (iii.) of perpetual rights of presentation to ecclesiastical benefices, and (iv.) of certain articles which are ascertained to be of national, scientific, historic or artistic interest. Moreover, certain British Government securities issued during the World War, and during a further period of one year after its termination, are also (under the terms of their issue), expressly exempted from the duty when held by persons who are neither domiciled nor ordinarily resident in the United Kingdom.

8. To avoid double taxation of movable property situated in a British dominion which, by reason of the same death is liable (i.) to the British estate duty (in the circumstances mentioned in paragraph 4 above) and (ii.) to a death duty in the dominion, arrangements exist under statutory powers by which, when certain conditions are fulfilled, such property pays only so much duty as

Great Britain: Rates of Estate Duty

Small estates—where the gross value does not exceed £300—a fixed duty of 30s. may be paid.
Small estates—where the gross value exceeds £300 and does not exceed £500—a fixed duty of 50s. may be paid.
} Inclusive of all other death duties.

Estates not exceeding £100 net are exempt. Agricultural property is rated on a slightly different basis.

Where the net principal value of the estate		Rate of duty % when the death occurred:

ESTAUNIÉ, EDOUARD (1862–), French novelist, was born at Dijon on Feb. 4, 1862. Estaunié, who became an academician in 1924, has written novels which carry on the great traditions of the French psychological novel. They are profound in their analysis, which is based on a detailed account of the characters, demanding prolonged attention from the reader. Throughout runs the thesis that the external life of each individual masks an internal life, usually very different and much more important. Incidentally, the novels provide vivid and penetrating pictures of provincial France. The more important of them are: *L'Empreinte* (1896), a study of the influence of Jesuit education; *La Vie secrète* (1908), the title of which is indicative of Estaunié's main contention; *Les Choses voient* (1913), in which three pieces of furniture relate the history of three generations; *L'Ascension de Monsieur Baslivre* (1920), the story of the official and the private life of a French civil servant; *L'Appel de la route* (1922).

ESTCOURT, RICHARD (1668–1712), English actor, made his first London appearance in 1704 as Dominick, in Dryden's *Spanish Friar,* and continued to take important parts at Drury Lane, being the original Pounce in Steele's *Tender Husband* (1705), Sergeant Kite in Farquhar's *Recruiting Officer,* and Sir Francis Gripe in Mrs. Centlivre's *Busybody.* He was an excellent mimic and a great favourite socially. Estcourt wrote a comedy, *The Fair Example, or the Modish Citizen* (1703), and *Prunella* (1704), an interlude.

EST DE FRANCE, COMPAGNIE DES CHEMINS DE FER, established in 1854, serves the east of France in various regions.

From Paris, three main railway lines serve this region: to the north the line from Paris to Charleville via Rheims, to the centre the line from Paris to Strasbourg via Nancy, to the south the line from Paris to Basle via Troyes. Two arteries assure the economical relations existing between the north and the south-east of France.

The Vosges region already utilises the motive power of its streams in a great number of flourishing industries. Portieux glass works, Baccarat and Cirey glass cutting works, Arches and Etival paper mills, materials imported from Alsace with bleaching on the grass. The Lorraine bearing is divided into three basins: the group from Nancy to Pont-St.-Vincent, Neuves-Maisons, Frouard, Pompey, Pont-à-Mousson; the Briey group the two centres of which are Joeuf and Homécourt; the Longwy group finally which includes Villerupt, Micheville, Saulnes, Longwy and Mont-Saint-Martin. Finally the Sarrebruck coal valley extends under the level Pont-à-Mousson, Nomény, but at a depth (800 to 1,200 metres) which has not yet allowed of its exploitation. The salt industry at Saint-Nicolas-du-Port, Rosières, Verangéville, Dombasle, is combined with that of soda, and the Solvay process has extended it.

The Eastern region does not lack tourist sites of repute. The valleys of the Vosges attract every year to Gérardmer, Bussang and Saint-Dié and a great number of other summer stations, an always increasing number of visitors. Its large towns are interesting to visit owing to the highly artistic remains preserved from olden times. There are numerous thermal stations, some of which, like Vittel, have attained a world-wide reputation. Where the railway ends there are to be found excellent services of motor cars to the outlying districts. (GRU.)

ESTE, one of the oldest of the former reigning houses of Italy. It is in all probability of Lombard origin, and descended, according to Muratori, from the princes who governed in Tuscany in Carolingian times. The lordship of the town of Este was first acquired by Alberto Azzo II., who also bore the title of marquis of Italy[1] (d. *c.* 1097); he married Kunitza or Kunegonda, sister of Welf or Guelph III., duke of Carinthia. Welf died without issue, and was succeeded by Welf IV., son of Kunitza, who married a daughter of Otto II., duke of Bavaria, and who obtained the duchy of Bavaria in 1070. Through him the house of Este became connected with the princely houses of Brunswick and Hanover. The Italian titles and estates were inherited by Folco I. (1060–1135), son of Alberto Azzo by his second wife Gersende, daughter of Herbert I., count of Maine. The house of Este played a great part in the history of mediaeval and Renaissance Italy, and it first comes to the front in the wars between the Guelphs and Ghibellines; as leaders of the former party its princes received at different times Ferrara, Modena, Reggio and other fiefs and territories.

Obizzo I., son of Folco, was the first to bear the title of marquis of Este. He entered into the Guelphic league against the emperor Frederick I., and was comprehended in the treaty of Venice of 1177 by which municipal *podestàs* (foreigners chosen as heads of cities to administer justice impartially) were instituted. He was elected podestà of Padua in 1178, and in 1184 he was reconciled with Frederick, who created him marquis of Genoa and Milan. By the marriage of his son Azzo to the heiress of the Marchesella family he acquired great influence in Ferrara although he was opposed by the hardly less powerful house of Torelli.

Obizzo died in 1194 and Azzo V. having predeceased him, the marquisate devolved on his grandson Azzo VI. (1170–1212), who became head of the Guelph party, and to him the people of Ferrara sacrificed their liberty by making him their first lord (1208). But during his lifetime civil war raged in the city, between the Este and

[1]Margrave of the Empire (*Marchio Sancti Imperii*) in Italy. (*See* MARQUESS.)

the Torelli, each party being driven out again and again. Azzo (also called Azzolino) died in 1212 and was succeeded by Aldobrandino I., who in 1213 concluded a treaty with Salinguerra Torelli, the head of that house, to divide the government of the city between them. On his death in 1215 he was succeeded by his brother Azzo VII. (1205–1264), surnamed Novello, but Salinguerra Torelli usurped all power in Ferrara and expelled Azzo (1222). In 1240 Pope Gregory IX. determined on another war against the emperor Frederick II., but deemed it wise to begin by crushing the chief Ghibelline houses. Thus Azzo found himself in league with the pope and various Guelph cities in his attempt to regain Ferrara. That town underwent a four months' siege, and was at last compelled to surrender; Salinguerra was sent to Venice as a prisoner, and Azzo ruled in Ferrara once more. The Ghibelline party was annihilated, but the city enjoyed peace and happiness within, although her citizens took part in the wars raging outside. The Guelph cause triumphed, Frederick being defeated several times, and after his death Azzo helped in crushing the terrible Eccelino da Romano (*q.v.*) who upheld the imperial cause, at the battle of Cassano (1259). He died in 1264 and was succeeded by Obizzo II. (1240–1293) his grandson, who in 1288 received the lordship of Modena, and that of Reggio in 1289.

Obizzo II. died in 1293 and was succeeded by his son Azzo VIII., but the latter's brothers, Aldobrandino and Francesco, who were to have shared in the government, were expelled and became his bitter enemies. The misgovernment of Azzo led to the revolt of Reggio and Modena, which shook off his yoke. He died in 1308, and left a disputed succession.

The history of the house now becomes involved and of little interest until we come to Nicholas III. (1384–1441), who ruled Ferrara, Modena, Parma and Reggio, waged many wars, was made general of the army of the Church, and in his later years governor of Milan, where he died, not without suspicion of poison. To him succeeded Lionello (1407–1450), a wise and virtuous ruler and a patron of literature and art; then Borso (1413–1471), his brother who was created duke of Modena and Reggio by the emperor Frederick III., and duke of Ferrara by the pope. In spite of the wars by which all Italy was torn, Ferrara enjoyed a period of peace and prosperity under Borso; he patronized literature, established a printing press at Ferrara, surrounded himself with learned men, and his court was of unparalleled splendour. He also protected industry and commerce, and ruled with great wisdom. His brother Ercole I. (1431–1505), who succeeded him in 1471, was less fortunate, and had to engage in a war with Venice, and by the peace of 1484 was forced to cede the district of Polesine to the republic. But the last years of his life were peaceful and prosperous. Boiardo the poet was his minister, and Ariosto obtained his patronage.

Ercole's daughter Beatrice d'Este (1475–1497), duchess of Milan, one of the most beautiful and accomplished princesses of the Italian Renaissance, was betrothed at the age of five to Lodovico Sforza (known as *il Moro*), duke of Bari, regent and afterwards duke of Milan, and was married to him in Jan. 1491. She availed herself of her position as mistress of one of the most splendid courts of Italy to surround herself with learned men, poets and artists, such as Niccolò da Correggio, Bernardo Castiglione, Bramante, Leonardo da Vinci and many others. In 1492 she visited Venice as ambassador for her husband in his political schemes, which consisted chiefly in a desire to be recognized as duke of Milan. On the death of Gian Galeazzo Sforza, Lodovico's usurpation was legalized, and after the battle of Fornovo (1495) both he and his wife took part in the peace congress of Vercelli between Charles VIII. of France and the Italian princes, at which Beatrice showed great political ability. But her brilliant career was cut short by death through childbirth, on Jan. 3, 1497. To her patronage and good taste are due to a great extent the splendour of the Castello of Milan, of the Certosa of Pavia and of many other famous buildings in Lombardy.

Her sister Isabella d'Este (1474–1539), marchioness of Mantua, was carefully educated both in letters and in the arts like Beatrice, and was married when barely sixteen to Francesco Gonzaga, marquis of Mantua (1490). She showed great diplomatic and political skill, especially in her negotiations with Cesare Borgia (*q.v.*), who had dispossessed Guidobaldo da Montefeltro, duke of Urbino, the husband of her sister-in-law and intimate friend Elisabetta Gonzaga (1502). She received the deposed duke and duchess, as well as other princes in the same condition, at her court of Mantua, and like her sister she gathered together many eminent men of letters and artists, Raphael, Andrea Mantegna and Giulio Romano being among those whom she employed. Both she and her husband were greatly influenced by Baldassare Castiglione (1478–1529), author of *Il Cortigiano,* and it was at his suggestion that Giulio Romano was summoned to Mantua to enlarge the Castello and other buildings. Isabella was "undoubtedly, among all the princesses of the 15th and 16th centuries, the one who most strikingly and perfectly personified the aspirations of the Renaissance" (Eugène Müntz); but her character was less attractive than that of her sister.

To Ercole I. succeeded his son Alphonso I. (1486–1534), the husband of Lucrezia Borgia (*q.v.*), daughter of Pope Alexander VI. He was gifted with great mechanical skill, and his artillery was of world-wide reputation. On the formation of the league of Cambrai against Venice in 1508, he was appointed to the supreme command of the papal troops by Julius II., but after the Venetians had sustained a number of reverses they made peace with the pope and joined him against the French. Alphonso was invited to co-operate in the new combination, and on his refusal war was declared against him, but although he began by losing Modena and Reggio, he subsequently inflicted several defeats on the papal troops. He fought on the side of the French at the battle of Ravenna (1512), from which, although victorious, they derived no advantage. Soon afterwards they retired from Italy, and Alphonso, finding himself abandoned, tried in vain to make his peace with the pope, through the mediation of Fabrizio Colonna. Leo X. proved equally bent on the destruction of the house of Este, when he too was cut off by death. Alphonso availed himself of the troubles of the papacy during the reign of the equally hostile Clement VII. to recapture Reggio (1523) and Modena (1527).

He died in 1534, and was succeeded by his son Ercole II. (1508–1559), who married Renée, daughter of Louis XII. of France, a friend of Calvin. The duke and his brother, Cardinal Ippolito the Younger, were patrons of literature and art, and the latter built the magnificent Villa d'Este at Tivoli. He was succeeded by Alphonso II. (1533–1597), remembered for his patronage of Tasso. With him the main branch of the family came to an end, and although at his death he bequeathed the duchy to his cousin Cesare (1533–1628), Pope Clement VIII., renewing the Church's hostility to the house of Este, declared that prince to be of illegitimate birth (a doubtful contention), and by a treaty with Lucrezia, Alphonso's sister, Ferrara was made over to the Holy See. Cesare held Modena and Reggio, but with him the Estensi cease to play an important part in Italian politics. For two centuries this dynasty had been one of the greatest powers in Italy, and its court was perhaps the most splendid in Europe.

The subsequent heads of the family were: Alphonso III., who retired to a monastery in 1629 and died in 1644; Francis I. (1610–1658), who commanded the French army in Italy in 1647; Alphonso IV. (1634–1662), the father of Mary Beatrice, the queen of James II. of England, who fought in the French army during the Spanish War, and founded the picture gallery of Modena; Francis II. (1660–1694), who originated the Este library, also at Modena, and founded the university; Rinaldo (1655–1737), through whose marriage with Charlotte Felicitas of Brunswick-Lüneburg the long-separated branches of the house of Este were reunited; Francis III. (1698–1780), who married the daughter of the regent Philip of Orleans. Francis III., wished to remain neutral during the war between Spain and Austria (1740), but the imperialists having occupied and devastated his duchy, he took the Spanish side and was appointed *generalissimo* of the Spanish army in Italy. He was re-established in his possessions by the treaty of Aix-la-Chapelle (1748), and on being reconciled with the empress Maria Theresa, he received from her the title of governor of Lombardy in 1754. With his son Ercole III. Rinaldo (1727–1803), who at the peace of Campoformio lost his duchy,

the male line of the Estensi came to an end. His only daughter, Marie Beatrice (d. 1829), was married to the archduke Ferdinand, third son of the emperor Francis I. Ferdinand was created duke of Breisgau in 1803, and at his death in 1806 he was succeeded by his son Francis IV. (*q.v.*), to whom the duchy of Modena was given at the treaty of Vienna in 1814. He died in 1846 and was succeeded by Francis V. (*q.v.*), who lost his possessions by the events of 1859. With his death in 1875 the title and estates passed to the archduke Francis Ferdinand, heir to the Austro-Hungarian throne. The children of Lady Augusta Murray, daughter of the earl of Dunmore, by her marriage with Augustus Frederick, duke of Sussex, sixth son of George III. of Great Britain, assumed the old name of d'Este, and claimed recognition as members of the royal family; but as the marriage was in violation of the royal marriages act of 1773, it was declared invalid, and their claims were set aside.

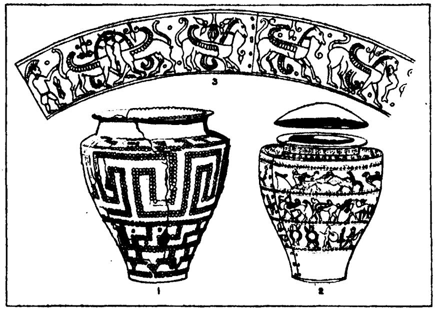
ESTE, town and Episcopal see, Venetia (anc. *Ateste*, *q.v.*), Italy, province of Padua, 20 m. S.S.W. of Padua by rail. Pop. (1921) 8,874 (town); 12,818 (commune). It lies 49 ft. above sea-level below and south of the Euganean Hills. The Adige ran close to the town until A.D. 589 but is now 9 m. S. of it. The external walls of the castle still rise above the town on the north. For its mediaeval history *see* above: ESTE (family of).

Archaeology.—Este was known to the Romans as Ateste and there are remains of Roman building. It has been reserved for the archaeologists to discover that Este was the chief centre of civilization in eastern Italy north of the Po for 800 years before the Roman occupation. A sacred precinct of the Venetic goddess Rhetia has been found here, and boundary stones of 135 B.C. divide the Ateste territory from that of Patavium.

To understand the prominent rôle played by this half-forgotten city it is necessary to understand its extraordinary geographical history. At the present day the Adige flows eight miles to the south of the town, but up to A.D. 589, when its course was suddenly changed by a catastrophic flood, the turbulent river washed the very walls. Vineyards and orchards, which now cover the whole countryside, were only planted in the Middle Ages, and actually hide a long line of sand-dunes in which the ancient cemeteries are situated. In Roman and pre-Roman days the place was practically a seaport, with almost the same outlook and natural advantages as the famous Adria at the mouth of the Po. Consequently the Atestines were so placed that they could cultivate a seaborne commerce, while at the same time they could travel by easy land routes round the head of the Gulf of Venice to Istria. On the south they were guarded by the broad and formidable stream of the Po, which effectually protected them against all attacks from that quarter. The Etruscans never penetrated into Venetia, and the Romans themselves never conquered the country, but peacefully occupied it under agreement with the inhabitants in 184 B.C. Down to the beginning of the Christian era the people of Este retained their own language and customs.

These Atestines—to use a geographical term which avoids all controversy as to the tribal identity or priority of Veneti, Euganei, or others—must be regarded as a branch of the same stock as the Villanovans. They were perhaps the latest of the cremating invaders to cross the Alps and who settled in northern Italy. Indeed, some Italian archaeologists have attempted to establish a 1st Atestine period contemporary with the 1st Benacci of Bologna; but the supposed traces of it are extremely slight, so that it is only with the beginning of the so-called second period that there is enough material for adequate treatment. This 2nd Atestine period may be dated from 950 B.C. to 500 B.C. That is to say it begins at the same time as the 2nd Benacci of Bologna and lasts down to the end of the Arnoaldi (*see* "VILLANOVANS"). The third period may be placed at 500 B.C. to 350 B.C., at which latter date the Gaulish invasions put an end to all the flourishing arts and industries of northern Italy. When these revived again to some extent under the Romans they had lost in Este, as in other places, a great deal of their individuality, and tended to become merged in the general complex of a civilization from which more of the local character had disappeared.



FROM R. MAC IVER, "IRON AGE OF ITALY" (CLARENDON PRESS)

RELICS EXCAVATED ON THE SITE OF THE ANCIENT TOWN OF ATESTE—MODERN ESTE—SHOW IT TO DATE BACK TO THE EIGHTH CENTURY B.C. Fig. 1.—Bronze studded pottery jar. Fig. 2.—Decorated jar and lid. Fig. 3.—Scene from a Boldù-Dolfin "situla" or bronze bucket

The close cousinship of the Bolognese Villanovans and the Atestines is proved by the complete identity not only of the burial rite, cremation, but of the forms and details of their graves. Moreover the contents of these graves are to a great extent identical during the whole of the second period. Amongst both peoples are found weapons and implements of the same type; there are the same bronze girdles, the same patterns of bracelets and necklaces, the same ornaments of amber and glass. Even the numerous varieties of *fibulae* are identical in the two regions and follow precisely the same steps of evolution. But with all this similarity there are also a good many points of difference; objects are found at Bologna which do not occur at Este and vice versa. It is particularly in respect of its metal work and the production of large bronze vases, or *situlae*, that Este shows its independence from the very first. The technique is the same as the Bolognese; casting was not used, but thin plates of copper or bronze were hammered out by hand and bent over to the required shape, after which they were fastened in place by rivets, often so emphasized as to form a simple ornamental motive. Large vessels made in this way occur very early in the second period, already assuming the form of the *situla* which was used as the ritual ossuary for holding the cremated ashes. On the other hand the large water jars of bronze which are among the best Bolognese products after the 8th century B.C. do not occur at Este. It is evident that these two great manufacturing centres remained quite separate and independent, though exercising a certain amount of reciprocal influence upon one another. Each was held in high repute over the whole of Italy and exported its wares far and wide, even beyond the Alps. But the Etruscan motives, which broke through the geometrical tradition and substituted decorations based on animal life and the growth of plants, did not reach Este before 500 B.C. though they had been gradually influencing Bolognese art for several generations before this.

A markedly individual product of the second period at Este is the pottery. This is a black ware, generically similar to the black ware found all over Italy and in many other parts of Europe during the Iron Age, but peculiar in the style of its decoration. The patterns are not incised, but are produced by embedding large studs of bronze in the wet clay before firing. This process results in turning out a very handsome and showy jar ornamented with

bold geometrical motives, such as those shown in fig. 1. It is a style obviously inspired by metal-work, the potter deliberately setting himself to produce the effect of repoussé ornament in a cheaper and more malleable material. The only other district in which this curious technique was practised is Falerii in central Italy. As the finest and most numerous examples, however, are found at Este, this city must be given the credit, if not for the invention, at least for the development of the idea. Bronze-studded pottery is closely delimited in chronological range. It disappears early in the third period, when it is replaced by a ware which is even more distinctively Atestine. This is a pottery painted with red ochre and graphite in alternate zones of cherry-red and lustrous black, the margins between each zone being defined by raised ridges of clay in relief. It was much admired and exported from end to end of Venetia, finding its way even as far west as Lago Maggiore.

The third period, especially the first half of the 5th century B.C., marks the zenith of Atestine art. In these two or three generations the creative spirit of the bronze-workers, stimulated by the introduction of foreign models from a variety of sources, of which the nearest and the most effective was the Etruscan, reached its high water mark. It is in the manufacture and decoration of bronze girdles and ossuaries that the spirit is chiefly displayed. The development and the decadence of this art may be traced in a fine series of bronze *situlae* in the local museum. It begins almost precisely in the year 500 B.C. with the Benvenuti *situla*, illustrated in fig. 2. This must be studied in connection with two other famous examples, the Certosa and the Arnoaldi *situlae* of Bologna. It was for a long time maintained, and is still held by some writers, that all three were produced in the workshops of Este; but of late years the best critical opinion inclines rather to regard the Certosa and Arnoaldi *situlae* as products of Bologna. In any case it is quite evident that the Benvenuti *situla* reproduces a general scheme of decoration inspired by Etruscan life and motives. The Certosa *situla* depicts an Etruscan funeral-procession and scenes from the life of the countryside. In the Benvenuti example there are similar scenes, the herdsman with his ox and dog, or the horse that is exhibited by the groom to his master. But with these are such purely Etruscan motives as the winged sphinx, as well as the stock Etruscan pictures of a military procession, a feast and a boxing match. Many *situlae* of this style were manufactured at Este and they were so popular that they were exported over the Alps even as far as the Danube. Atestine *situlae* or imitations of them have been found over an area which extends in a half-circle from Krain on the east to the Brenner on the west; the most famous specimens are those of Moritzing, Matrei, Welzelach, Meclo, Watsch, Kuffarn and Hallstatt. All these Alpine versions, however, are rather clumsy travesties of the fine Italian originals.

The artistic spirit of Este itself began to degenerate very appreciably in the 4th century. This can be seen from the *situlae* of the Boldù-Dolfin graves, which, though they are technically as well made as those of three or four generations earlier, betray a total lack of artistic taste. Instead of the fresh scenes of country life or the pleasant little pictures of cattle, deer and birds which gave a pleasing grace to the bronzes of the 5th century, the Boldù-Dolfin ossuaries show only clumsy imitations of fantastic mythological beasts, taken from the now unmeaning répertoire of a tenth-hand copyist (fig. 3). The artist has been swamped in the progress of mass-production; the Atestine factories had become too successful. Consequently the art of the 4th century B.C. has lost all freedom and individuality. As a factory centre Este was doubtless important down to Roman times, but it contributed nothing of value to civilization after A.D. 400. The student of manners, however, will find much that is interesting in the figurines of the Baratela collection, and the philologist values the Euganean inscriptions of the 4th century A.D. which are to be seen in the museum.

BIBLIOGRAPHY.—D. Randall-MacIver, *The Iron Age in Italy* (Oxford, Clarendon Press, 1927), which gives the Italian authorities. The *situlae* have been the subject of an extensive literature. Minutely studied by G. Ghirardini in *Monumenti Antichi* and in recent years by P. Ducati in a special monograph on *La situla della Certosa*, they have been well treated, as concerns their general date and history by M. Hoernes in his *Urgeschichte der bildenden Kunst*. (D. R.-M.)

ESTÉBANEZ CALDERÓN, SERAFÍN (1799–1867), Spanish author, known as "El Solitario." His *Escenas andaluzas* (1847), written in a curiously affected style, is a vivid record of picturesque scenes and local customs despite its eccentric mannerisms and its archaic vocabulary. He left an unfinished history, *De la conquista y pérdida de Portugal* (1883).

See A. Cánovas del Castillo, *"El Solitario" y su tiempo* (1883).

ESTELLA, a town of northern Spain, province of Navarre, on the left bank of the river Ega, 15 m. W.S.W. of Pamplona. Pop. (1920) 5,603. Estella, built on the site of a former Roman settlement, contains several monasteries, three fine mediaeval churches, and a college which was formerly a university. It has cloth-making and leather industries and a considerable trade in fruit, wine and cattle. In 1928 a railway from Victoria was approaching completion. Situated amid mountains commanding the roads from Castile and Aragon, Estella occupies a position of considerable strategic importance. It was long the headquarters of Don Carlos, who was proclaimed king here in 1833. In 1874, when driven from other places, the Carlists retired to Estella but on Feb. 16, 1876; those in the town finally surrendered. (For an account of the Carlist rising *see* SPAIN: *History*.)

ESTERHÁZY OF GALÁNTHA, a noble Magyar family. Its origin has been somewhat doubtfully traced to Salamon of Estoras, whose sons Péter and Illyés divided their patrimony in 1238. Péter founded the family of Zerházy, and Illyés that of Illyesházy, which became extinct in the male line in 1838. The first member of the family to emerge definitely into history was Ferencz Zerházy (1563–94), vice lord-lieutenant of the county of Pressburg, who took the name of Esterházy when he was created *Freiherr* of Galántha, an estate acquired by the family in 1421. His eldest son, Dániel (d. 1654), founded the house of Czesznek, the third, Pál (d. 1641), the line of Zólyom (Altsohl), and the fourth, Miklós, that branch of the family which occupies the most considerable place in Hungarian history, that of Fraknó or Forchtenstein.

This MIKLÓS [Nicholas] ESTERHÁZY of Galántha (1582–1645) was born at Galántha on April 8, 1582. He opposed the two great Protestant champions of the period, Gabriel Bethlen (Bethlen Gabor) and George I. Rákóczy. In 1611 he married Orsolyá, the widow of the wealthy Ferencz Mágocsy, thus coming into possession of her gigantic estates, and in 1622 he acquired Fraknó. He received many honours from Matthias II. and Ferdinand II., including the order of the Golden Fleece. At the diet of Sopron, 1625, he was elected palatine of Hungary. As a diplomatist he powerfully contributed to bring about the peaces of Nikolsburg (1622) and Linz (1645) (*see* HUNGARY: *History*). His political ideal was the consolidation of the Habsburg dynasty as a means towards freeing Hungary from the Turkish yoke and he himself, in 1623, defeated the Turks on the banks of the Nyitra. He died at Nagy-Heflán on Sept. 11, 1645, leaving five sons.

See *Works of Nicholas Esterházy*, with a biography by Ferencz Toldi (Hung.) (Pest, 1852); *Nicholas Count Esterházy, Palatine of Hungary* (a biography, Hung.) (Pest, 1863–70).

His third son PAL [Paul] (1635–1713), prince palatine, founded the princely branch of the family of Esterházy. He was born at Kis Marton (Eisenstadt) on Sept. 7, 1635. In 1663 he fought, along with Miklós Zrinyi, against the Turks, and distinguished himself under Montecuculi. In 1667 he was appointed commander-in-chief in south Hungary, where he defeated the malcontents at Leutschau and Györk. In 1681 he was elected palatine. In 1683 he participated in the deliverance of Vienna from the Turks, and entered Buda in 1686 at the head of 20,000 men. Thoroughly reactionary, and absolutely devoted to the Habsburgs, he contributed more than any one else to the curtailing of the privileges of the Magyar gentry in 1687, when he was created a prince of the Empire, with (in 1712) succession to the first-born of his house. His "aulic tendencies" made him so unpopular that his offer of mediation between the Rákóczy insurgents and the government was rejected by the Hungarian diet, and the negotiations, which led to the peace of Szatmár, were entrusted to János Pállfy. He died on March 26, 1713. He loved the arts and sciences, wrote

several religious works and was one of the chief compilers of the *Trophaeum Domus Inclytae Estoratianae.*

See Lajos Merényi, *Prince Paul Esterházy* (*Hung.*) (Budapest, 1895).

Prince PÁL ANTAL, grandson of the prince palatine Pál, was a distinguished soldier, who rose to the rank of field-marshal in 1758. On his death in 1762 he was succeeded by his brother.

Prince MIKLÓS JOZSEF [Nicholas Joseph] (1714–90), also a brilliant soldier, was a patron of the fine arts. Emperor Joseph II. conferred the princely title, which had previously been limited to the eldest-born of the house, on all his descendants, male and female. Esterházy died in Vienna on Sept. 28, 1790. He rebuilt in the renaissance style Schloss Esterházy, the splendour of which won for it the name of the Hungarian Versailles. Haydn was for thirty years conductor of his private orchestra and general musical director, and many of his compositions were written for the private theatre and the concerts of this prince.

His grandson, Prince MIKLÓS [Nicholas] (1765–1833) was born on Dec. 12, 1765. He made at Vienna an important collection of paintings and engravings (which came to the Hungarian Academy at Budapest in 1865), and at his summer palace of Kis Marton (Eisenstadt) he erected a monument to Haydn. When the French invaded Austria in 1797, he raised a regiment of 1000 men at his own expense. In 1809, when Napoleon invited the Magyars to elect a new king to replace the Habsburgs, overtures were made to Prince Nicholas, who refused the honour and, further, raised a regiment of volunteers in defence of Austrian interests; but his immense expenditures in this way and on building and the arts involved the family in financial difficulties for two generations. He died at Como on Nov. 24, 1833.

His son, Prince PÁL ANTAL [Paul Anthony] (1786–1866), entered the diplomatic service. In 1806 he was secretary of the embassy in London, and in 1807 worked with Prince Metternich in the same capacity in Paris. In 1810 he was accredited to the court of Dresden, where he tried in vain to detach Saxony from Napoleon, and in 1814 accompanied his father on a secret mission to Rome. He took a leading part in all the diplomatic negotiations consequent upon the wars of 1813–15, especially at the congress of Châtillon, and on the conclusion of peace was, at the express desire of the prince regent, sent as ambassador to London. In 1824 he represented Austria as ambassador extraordinary at the coronation of Charles X., and was the premier Austrian commissioner at the London conferences of 1830–36. In 1842 he attached himself to "the free-principles party." He was minister for foreign affairs in the first responsible Hungarian ministry (1848), but resigned his post in Sept. because he could see no way of reconciling the court with the nation. His last years were spent in comparative poverty and isolation, as even the Esterházy-Forchtenstein estates were unequal to the burden of supporting his fabulous extravagance and had to be placed in the hands of curators.

The cadet branch of the house of Fraknó, the members of which bear the title of count, was divided into three lines by the sons of Ferencz Esterházy (1641–83).

The eldest of these, Count ANTAL (1676–1722), distinguished himself in the war against Rákóczy in 1703, but changed sides in 1704 and commanded the left wing of the Kuruczis at the engagements of Nagyszombat (1704) and Vereskö (1705). In 1706 he defeated the imperialist general Guido Stahremberg and penetrated to the walls of Vienna. Still more successful were his operations in the campaign of 1708, when he ravaged Styria, twice invaded Austria, and again threatened Vienna, on which occasion the emperor Joseph narrowly escaped falling into his hands. In 1709 he was routed by the superior forces of General Sigbert Heister at Palota, but retreated very skilfully. In 1710 he joined Rákóczy in Poland and accompanied him to France and Turkey. He died in exile at Rodosto on the shores of the Black Sea. His son Bálint József [Valentine Joseph], by Anna Maria Nigrelli, entered the French army, and was the founder of the Hallewyll, or French, branch of the family, which became extinct in the male line in 1876 with Count Ladislas.

See *Count Esterházy's Campaign Diary* (Hung.), ed. by K. Thaly (Pest, 1901).

Count BALINT MIKLÓS (1740–1805), son of Bálint József, was an enthusiastic partisan of the duc de Choiseul, on whose dismissal, in 1764, he resigned the command of the French regiment of which he was colonel. He conveyed to Marie Antoinette the portrait of Louis XVI. on the occasion of their betrothal, and the close relations he maintained with her after her marriage were more than once the occasion of remonstrance on the part of Maria Theresa. At the French court he stood in high favour with the comte d'Artois. He was raised to the rank of maréchal de camp, and made inspector of troops in the French service in 1780. At the outbreak of the French Revolution, he was stationed at Valenciennes and facilitated the escape of the French *emigrés* by way of Namur; but, in 1790, he hastened back to Paris to assist the king. At the urgent entreaty of the comte d'Artois in 1791 he quitted Paris for Coblenz, accompanied Artois to Vienna and was sent to the court of St. Petersburg the same year to enlist the sympathies of Catherine II. for the Bourbons. He died at Grodek in Volhynia on July 23, 1805.

See *Mémoires*, ed. by E. Daudet (Fr.) (Paris, 1905), and *Lettres* (Paris, 1906).

Two other sons of Count Ferencz (d. 1685), Ferencz and József, founded the houses of Dotis and Cseklész (Landschütz) respectively. Of their descendants, Count MÓRICZ (1807–90) of Dotis, Austrian ambassador in Rome until 1856, became in 1861 a member of the ministry formed by Anton Schmerling and in 1865 joined the clerical cabinet of Richard Belcredi. His bitter hostility to Prussia helped to force the government of Vienna into the war of 1866. His official career closed in 1866, but he remained one of the leaders of the clerical party.

ESTERS, in organic chemistry, compounds formed by the condensation of an alcohol and an acid, with elimination of water. Since this process is analogous to the neutralization of an acid by a basic hydroxide in salt formation these esters were formerly called ethereal salts. But this older term is misleading, since esters, unlike salts, are not conductors of electricity in solution. In the case of the polybasic acids, all the hydrogen atoms can be replaced in this way, and the compounds formed are known as neutral esters. If, however, some of the hydrogen of the acid remains undisplaced, then acid esters result. These acid esters retain some of the characteristic properties of the acids, forming, for example, salts, with basic oxides. Esters may be prepared by heating the silver salt of an acid with an alkyl iodide; by heating the alcohols or alcoholates with an acid chloride; by distilling the anhydrous sodium salt of an acid with a mixture of the alcohol and concentrated sulphuric acid; or by heating for some hours on the water bath a mixture of an acid and an alcohol with a small quantity of hydrochloric or sulphuric acids (E. Fischer and A. Speier, 1896).

The esters of the aliphatic and aromatic acids are colourless neutral liquids, which are generally insoluble in water, but readily dissolve in alcohol and ether. Methyl oxalate, $C_2O_4(CH_3)_2$, is a solid (m.p. 54° C). Many possess a fragrant odour and are prepared in large quantities for use as artificial fruit essences; for example, *ethyl acetate* (acetic ether) $CH_3{\cdot}CO_2{\cdot}C_2H_5$, *butyl acetate, ethyl butyrate,* $C_3H_7{\cdot}CO_2C_2H_5$ (b.p. 121° C, odour of pineapple), *isoamyl isovalerate* $C_4H_9{\cdot}CO_2{\cdot}C_5H_{11}$ (b.p. 196°, odour of apples). They hydrolyse readily when boiled with solutions of caustic alkalies or mineral acids, yielding the constituent acid and alcohol. When heated with ammonia, they yield acid amides (*q.v.*). With Grignard reagents (*q.v.*) they furnish tertiary alcohols, except in the case of ethyl formate $H{\cdot}CO_2{\cdot}C_2H_5$ (b.p. 55° C), where secondary alcohols are obtained.

N. Menschutkin (1879–82) examined the rate of esterification of many acids with alcohols and found that the normal primary alcohols were all esterified at about the same rate, the secondary alcohols more slowly than the primary, and the tertiary alcohols still more slowly. The nature of the acid used affected the result, for in an homologous series of acids it was found that as the mole-

cule of the acid became more complex, the rate of esterification became less. The formation of an ester by the interaction of an acid with an alcohol is a "reversible" or "balanced" action, for as M. Berthelot and L. Péan de St. Gilles (1862) have shown in the case of the formation of ethyl acetate (b.p. 75° C) from ethyl alcohol and acetic acid, a point of equilibrium is reached beyond which the reacting system cannot pass, unless the system be disturbed in some way by the removal of one of the products of the reaction. V. Meyer (1894) showed that in benzenoid compounds ortho-substituents hindered esterification of alcohols by acids in the presence of hydrochloric acid, this hindrance being particularly marked when two substituents are present in the ortho positions to the carboxyl group. In such a case the ester is best prepared by the action of an alkyl halide on the silver salt of the acid, and when once prepared can only be hydrolysed with great difficulty. The oils, fats and waxes (*q.v.*) are largely the esters of the higher fatty acids and glycerol. The esters of the higher fatty acids when distilled under atmospheric pressure are decomposed into an olefine and a fatty acid.

Esters of the mineral acids may be prepared by the general methods described above. The neutral esters are as a rule insoluble in water and distil unchanged; on the other hand, the acid esters are generally soluble in water, are non-volatile, and form salts with bases. *Ethyl hydrogen sulphate* (sulphovinic acid), $C_2H_5{\cdot}HSO_4$, obtained by the action of concentrated sulphuric acid on alcohol, is a colourless oily liquid with acid reaction, slowly decomposing in aqueous solution. On heating it forms diethyl sulphate and sulphuric acid. *Dimethyl sulphate,* $(CH_3)_2SO_4$, a colourless liquid which boils at 187°–188° C, with partial decomposition, is used as a methylating agent. Great care should be taken in using dimethyl and diethyl sulphates, as the respiratory organs are seriously affected by the vapours. *Ethyl nitrate,* $C_2H_5{\cdot}ONO_2$, a colourless liquid which boils at 86·3° C, is prepared by the action of nitric acid on ethyl alcohol. *Ethyl nitrite,* $C_2H_5{\cdot}ONO$, is a liquid which boils at 18° C; the crude product obtained by distilling a mixture of alcohol, sulphuric and nitric acids and copper turnings is used in medicine under the name of "sweet spirits of nitre." *Amyl nitrite,* $C_5H_{11}{\cdot}ONO$, boils at 96° C, and is employed in the preparation of anhydrous diazonium salts (*see* DIAZO-COMPOUNDS). It is also used in medicine.

ESTES PARK, a village at the eastern entrance to the Rocky Mountain national park, in Larimer county, Colo., U.S.A., 55m. N.W. of Denver, at an altitude of 7,500 feet. The nearest railroad station is Lyons, on the Burlington route, 21m. south-east. The population of the precinct was 539 in 1920. It is an important touring centre and summer resort, with some 30 hotels. There is an air port, Stanley field.

ESTHER. The book of Esther relates how a Jewish maiden, cousin and foster-daughter of Mordecai, became the queen of the Persian king Ahasuerus (Xerxes, *see* AHASUERUS); how Esther and Mordecai frustrated Haman's endeavour to extirpate the Jews; how Haman, the grand vizier, fell, and Mordecai succeeded him; how Esther obtained the king's permission for the Jews to destroy all who might attack them on the day which Haman had appointed by lot for their destruction; and, lastly, how the feast of Purim (Lots?) was instituted to commemorate their deliverance.

The story of Esther is the work of a skilled narrator. The principal characters are well drawn, the style is simple, the interest sustained. There are two very conspicuous blemishes: the lack of any religious element and the apparent delight in the wholesale slaughter of gentiles. There is no allusion to a divine being, no mention of religious feeling or observance (except fasting). The plane of exaggeration on which the whole narrative is based must be taken into account (a banquet lasting 180 days, the 12 months perfuming of each maiden before her presentation to the king, Esther's preparation lasting four years, Haman's gallows 50 cubits high, a year's warning to the victims of the plot, etc.) was doubtless designed to weaken the impression of reality. The book aims to paint a stirring picture of the supposed events which led to the institution of the festival of Purim, celebrated on the 14th and 15th of Adar (*see* PURIM), and thus to help ensure its perpetual observance; but historical verity is disclaimed at the outset (precisely as is the case in the book of Judith).

The true origin of the feast remains obscure, and even the name has not been satisfactorily explained. Since the names Esther and Mordecai are derived from Ishtar and Marduk, some scholars (notably Zimmern and Jensen) have sought to find the basis of the story in Babylonian, Persian or Elamite mythology. (*See* Paton, *Comm.*, pp. 76–94.) No one of these attempts is convincing, however.

Esther is one of the latest books of the Old Testament. This appears plainly in the character of the Hebrew in which it is written (Driver, *Introd.;* Paton, p. 59). Kuenen's conjectured date of its composition, *c.* 130 B.C., seems to have the best support, and has found favour with many scholars. We first hear of the feast of Purim in 2 Macc. xv. 36 (1st century B.C.). The remarkable subscription to the standard Greek recension gives the date, 114–113 B.C., at which the Greek translation (of our Hebrew, or of an expanded text?) was brought to Egypt. The book enjoyed great popularity among the Jews, as shown by the many recensions and by the distinction of a special scroll (*megillah*). Our Hebrew seems to give the oldest and best version. The standard Greek renders a somewhat longer text, besides containing extensive additions (*see* below). Another Greek recension, abbreviated and differing in other respects, was published by Lagarde (*Libr. Vet. Test pars prior*). The Old Latin, Jerome's Vulgate, two Targums (from the Gaonic period), and a late and unimportant Syriac version, are also to be mentioned. The variation in the principal texts (Hebrew, Greek and Latin) seems to be due mainly to reproduction from memory. Although much read, the book was not easily ranked as sacred scripture. The Jews gave it admission to the canon only after much controversy, and among the early Christians it was often rejected; the Nestorian Church, especially, continued to ignore it.

BIBLIOGRAPHY.—The most complete account of all matters relating to the book of Esther is given by L. B. Paton's *Book of Esther* (Int. Crit. Commentary, 1908). *See* also his "Text-critical Apparatus" in *O.T. and Semitic Studies in Memory of W. R. Harper* (1908), ii., pp. 1–51; the comms. of Wildeboer (1898) and Siegfried (1901), Nöldeke's article "Esther" in the *Ency. Biblica.*, and the articles "Esther" and "Megillot" in the *Jewish Encyclopaedia*.

(T. K. C.; C. C. T.)

Additions to Book of Esther.—This term designates the six long passages which are found in the standard Greek version, and now have a place in the O.T. Apocrypha. They are the following: A (preceding Heb. chap. i.): Mordecai's dream, and his discovery of a conspiracy. B (following Heb. iii. 13): the letter of the king, ordering the extermination of "a certain evilly disposed people." C (following Heb. chap. iv.): prayers of Mordecai and Esther. D: an expanded narrative, 16 verses, replacing Heb. v. 1, 2. E (following Heb. viii. 12): the letter of the king in favour of the Jews. F (following the last verse, x. 3, of Heb.) includes: (*a*) Mordecai's interpretation of his dream, and his declaration as to the institution of Purim; (*b*) the subscription giving a date (*see* above).

The earliest sure attestation of the additions is given by Josephus, *Ant.* xi. 6. The "Lucianic" Greek edited by Lagarde (*see* above) contains them; so also does the Old Latin, translated from still another Greek version and containing further expansions as well as omissions. Jerome, in the Vulgate, rendered the additions from the Greek, beginning with F at the close of his translation of the Hebrew book, and continuing with the others in their disconnected sequence. The meaningless disorder in the English Apocrypha is the result of translating Jerome's text without rearrangement or explanation.

The additions cannot have been present in the original Hebrew. Their character, both literary and religious, is markedly different, and their omission would be inexplicable. They testify, on the one hand, to the desire to introduce into the book the religious element which is so conspicuously lacking, and on the other hand to the lively circulation of the story, especially in the first decades of its popularity, in a variety of freely handled versions, Hebrew, Greek and Aramaic. The additions themselves, moreover, represent more than one original language and at least two distinct re-

censions. It is beyond question that B and E (*see* above) were composed in Greek, and that they never stood in other than Greek forms of the story. The style in which they are written is conclusive as to this, and they are doubtless the work of one and the same hand. It is equally capable of demonstration that the Greek of A, C, D and F(*a*) is the result of translation from Hebrew; these sections stood originally in a Hebrew book. The original language of F(*b*) (the subscription) was presumably Greek, though this can hardly be declared certain.

BIBLIOGRAPHY.—Paton's *Commentary* and his *Critical Notes* (*see* above); also Fritzsche, *Handbuch zu den Apokryphen*, i. (1851), pp. 69–108; Fuller, in the *Speaker's Apocrypha*, i. (1888), pp. 361–402 (with translations from the Targums); Ryssel, in Kautzsch's *Apokryphen;* Gregg, in Charles' *Apocrypha*. The Aramaic version (late) of Mordecai's dream is given in Lagarde's *Hagiographa Chaldaice* and Merx's *Chrestomathia Targumica*. (C. C. T.)

ESTHERVILLE, a city of northern Iowa, U.S.A., on the Des Moines river, 5m. from the Minnesota State line; the county seat of Emmet county. It is served by the Rock Island and the Minneapolis and St. Louis railways. The population (90% native white) was 5,084 in 1925 (State census). It is the trading centre for a farming, stock-raising and dairying region, and has wagon shops, cement works and a tile factory. The city was founded about 1858 and incorporated in 1881. Since 1916 it has had a city-manager form of government.

ESTIENNE or **ÉTIENNE** (latinized to Stephanus), a French family of scholars and printers.

The founder of the house was HENRI ESTIENNE (d. 1520), of a noble family of Provence, who came to Paris in 1502, and set up a printing establishment at the top of the rue Saint-Jean de Beauvais. He died in 1520, and, his three sons being minors, the business was carried on by his foreman, Simon de Colines, who in 1521 married his widow.

ROBERT ESTIENNE (1503–1559) was Henri's second son. After his father's death he acted as assistant to his stepfather, and superintended the printing of a Latin edition of the New Testament (1523). He had intimate relations with the new Evangelical preachers and soon after this time definitely joined the Reformed Church. In 1526 he became head of the firm, and adopted as his device the celebrated olive-tree. In 1528 he married Perrette, a daughter of the scholar and printer Josse Bade (Jodocus Badius), and in the same year he published his first Latin Bible, an edition in folio, upon which he had been at work for the last four years. In 1532 appeared his *Thesaurus linguae Latinae* (later editions 1536, 1543), a dictionary of Latin words and phrases, which as late as 1734 was considered worthy of being re-edited. In 1539 Robert was appointed king's printer for Hebrew and Latin, and in 1540 for Greek. In 1541 he was entrusted by Francis I. with the task of procuring from Claude Garamond, the engraver and type-founder, three sets of Greek type for the royal press. With the middle size Robert printed the *editio princeps* of the *Historia Ecclesiastica* of Eusebius and others (1544). The smallest size was first used for the 16mo edition of the New Testament known as the *O mirificam* (1546), while with the largest size was printed the magnificent folio of 1550. This edition brought the printer into disputes with the faculty of theology, and in 1551 he left his native town and took refuge at Geneva, where he published in 1552 a caustic answer to his persecutors under the title *Ad censuras theologorum Parisiensium. . . .* A French translation was published by him in the same year (printed in Rénouard's *Annales de l'imprimerie des Estienne*). At Geneva Robert became an ardent partisan of Calvin, several of whose works he published. He died there on Sept. 7, 1559.

The text of Etienne's New Testament of 1550, either in its original form or in such slightly modified form as it assumed in the Elzevir text of 1634, remains to this day the traditional text. But this is due rather to its typographical beauty than to any critical merit. The readings of the fifteen mss. which Robert's son Henri had collated for the purpose, were merely introduced into the margin. The text was still almost exactly that of Erasmus. It was, however, the first edition ever published with a critical apparatus of any sort. Of the whole Bible Robert printed eleven editions—eight in Latin, two in Hebrew and one in French; while of the New Testament alone he printed twelve—five in Greek, five in Latin and two in French. In the Greek New Testament of 1551 (printed at Geneva) the present division into verses was introduced for the first time. The *editiones principes* which issued from Robert's press were eight in number, viz. *Eusebius*, including the *Praeparatio evangelica* and the *Demonstratio evangelica* as well as the *Historia ecclesiastica* already mentioned (1544–1546), *Moschopulus* (1545), *Dionysius of Halicarnassus* (February 1547), *Alexander Trallianus* (January 1548), *Dio Cassius* (January 1548), *Justin Martyr* (1551), *Xiphilinus* (1551), *Appian* (1551), the last being completed, after Robert's departure from Paris, by his brother Charles, and appearing under his name. These editions, all in folio, except the *Moschopulus*, which is in 4to, are unrivalled for beauty. Robert also printed numerous editions of Latin classics, of which perhaps the folio *Virgil* of 1532 is the most noteworthy, and a large quantity of Latin grammars and other educational works, many of which were written by Maturin Cordier, his friend and co-worker in the cause of humanism.

CHARLES ESTIENNE (1504 or 1505–1564), the third son of Henri, was also a man of considerable learning. He studied medicine, took his doctor's degree at Paris, and was for a time tutor to Jean Antoine de Baïf, the future poet. In 1551, when Robert Estienne left Paris for Geneva, Charles, who had remained a Catholic, took charge of his printing establishment, and in the same year was appointed king's printer. In 1561 he became bankrupt, and he is said to have died in a debtors' prison.

His principal works are *Praedium Rusticum* (1554), a collection of tracts which he had compiled from ancient writers on various branches of agriculture, and which continued to be a favorite book down to the end of the 17th century; *Dictionarium historicum ac poëticum* (1553), the first French encyclopaedia; *Thesaurus Ciceronianus* (1557), and *De dissectione partium corporis humani libri tres*, with well-drawn woodcuts (1548). He also published a translation of an Italian comedy, *Gli Ingannati*, under the title of *Le Sacrifice* (1543; republished as *Les Abusez*, 1549), which had some influence on the development of French comedy; and *Paradoxes* (1553), an imitation of the *Paradossi* of Ortensio Landi.

HENRI ESTIENNE (1531–1598), sometimes called Henri II., was the eldest son of Robert. In the preface to his edition of Aulus Gellius (1585), addressed to his son Paul, he gives an interesting account of his father's household, in which Latin was used as a common language. At fifteen he became a pupil of Pierre Danès, at that time the first Greek scholar in France. In 1545 he began to attend the lectures of Jacques Toussain, royal professor of Greek, and was employed by his father to collate a ms. of Dionysius of Halicarnassus. In the year 1547 he went to Italy, where he spent three years in hunting for and collating mss. and in intercourse with learned men. In 1550 he visited England, where he was favourably received by Edward VI., and then Flanders, where he learnt Spanish. In 1551 he joined his father at Geneva, which henceforth became his home. In 1554 he published, as the firstfruits of his researches, two first editions, viz. a tract of Dionysius of Halicarnassus and the so-called "Anacreon." In 1556 he discovered at Rome ten new books (xi.–xx.) of Diodorus Siculus. In 1557 he issued at Geneva three first editions, viz. *Athenagoras, Maximus Tyrius*, and some fragments of Greek historians, including Appian's Ἀννιβαλική, and Ἰβηρική and an edition of Aeschylus, in which for the first time the *Agamemnon* was printed in entirety and as a separate play. In 1559 he printed a Latin translation from his own pen of Sextus Empiricus, and an edition of Diodorus Siculus with the new books. Under his father's will he became in 1559 owner of his press, subject, however, to the condition of keeping it at Geneva. In 1566 he published his best-known French work, the *Apologie pour Hérodote*. Some passages being considered objectionable by the Geneva consistory, he was compelled to cancel the pages containing them. Within sixteen years twelve editions were printed. In 1572 he published his *magnum opus*, the *Thesaurus Graecae linguae* (5 vols. fol.). The publication in 1578 of his *Deux Dialogues du nouveau françois italianizé* brought him into a fresh dispute with the consistory. To avoid their censure he went to Paris, and resided at the French court for a year. On his return to Geneva he was summoned before the consistory, and, proving contumacious, was imprisoned for a week. From this time his life became more and more of a nomad one. He is to be found at Basel, Heidelberg, Vienna, Pest, everywhere but at Geneva, these journeys being undertaken partly in the hope of procuring patrons and purchasers. His press stood nearly at a standstill. A few editions of classical authors were brought out, but each successive one showed a

falling off. Such value as the later ones had was chiefly due to the notes furnished by Casaubon, who in 1586 had married his daughter Florence. In 1597 he left Geneva for the last time. After visiting Montpellier, where Casaubon was now professor, he started for Paris, and died at Lyons at the end of January 1598.

Few men have ever served the cause of learning more devotedly. For over thirty years the amount which he produced, whether as printer, editor or original writer, was enormous. The productions of his press, though printed with the same beautiful type as his father's books, are, owing to the poorness of the paper and ink, inferior to them in general beauty. The best, perhaps, from a typographical point of view, are the *Poëtae Graeci principes* (folio, 1566), the *Plutarch* (13 vols. 8vo, 1572), and the *Plato* (3 vols. folio, 1578). It was rather his scholarship which gave value to his editions. He was not only his own press-corrector but his own editor. Though by the latter half of the 16th century nearly all the important Greek and Latin authors that we now possess had been published, his untiring activity still found some gleanings. Eighteen first editions of Greek authors and one of a Latin author are due to his press. Estienne only resorted to conjecture when authority failed him. He was the first to show what conjecture could do towards restoring a hopelessly corrupt passage. The work, however, on which his fame as a scholar is most surely based is the *Thesaurus Graecae linguae*. After making due allowance for the fact that considerable materials for the work had been already collected by his father, and that he received considerable assistance from the German scholar Sylburg, he is still entitled to the very highest praise as the producer of a work which was of the greatest service to scholarship and which in those early days of Greek learning could have been produced by no one but a giant. Two editions of the *Thesaurus* were published in the 19th century—at London by Valpy (1815–1825) and at Paris by Didot (1831–1863).

It was one of Henri Estienne's great merits that, unlike nearly all the French scholars who preceded him, he did not neglect his own language. In the *Traité de la conformité du langage françois avec le Grec* (published in 1565, but without date; ed. L. Feugère, 1850), French is asserted to have, among modern languages, the most affinity with Greek, the first of all languages. *Deux Dialogues du nouveau françois italianizé* (Geneva, 1578; ed. P. Ristelhuber, 2 vols., 1885) was directed against the fashion prevailing in the court of Catherine de' Medici of using Italian words and forms. The *Project du livre intitulé de la Précellence du langage françois* (Paris, 1579; ed. E. Huguet, 1896) treats of the superiority of French to Italian. An interesting feature of the *Précellence* is the account of French proverbs, and, Henry III. having expressed some doubts as to the genuineness of some of them, Henri Estienne published, in 1594, *Les Premices ou le I. livre des Proverbes epigrammatizez* (never reprinted and very rare).

Finally, there remains the *Apologie pour Hérodote*, his most famous work. The ostensible object of the book is to show that the strange stories in Herodotus may be paralleled by equally strange ones of modern times. Virtually it is a bitter satire on the writer's age, especially on the Roman Church. A modern edition was published by Liseux (ed. Ristelhuber, 2 vols., 1879), after one of the only two copies of the original uncancelled edition that are known to exist.

The primary authorities for an account of the Estiennes are their own works. In the garrulous and egotistical prefaces which Henri was in the habit of prefixing to his editions will be found many scattered biographical details. Twenty-seven letters from Henri to John Crato of Crafftheim (ed. F. Passow, 1830) have been printed, and there is one of Robert's in Herminjard's *Correspondence des Réformateurs dans de pays de langue française* (9 vols. published 1866–1897), while a few other contemporary references to him will be found in the same work. The secondary authorities are Janssen van Almeloveen, *De vitis Stephanorum* (Amsterdam, 1683); Maittaire, *Stephanorum historia* (London, 1709); A. A. Rénouard, *Annales de l'imprimerie des Estienne* (2nd ed., Paris, 1843); the article on Estienne by A. F. Didot in the *Nouv. Biog. gén.*; Mark Pattison, *Essays*, i. 67 ff. (1889); L. Clément, *Henri Estienne et son œuvre française* (Paris, 1899). There is a good account of Henri's *Thesaurus* in the *Quart. Rev.* for January 1820, written by Bishop Blomfield.

ESTIMATES. In British national finance, the expenditure of public money is safeguarded by the yearly preparation, by each spending department of State, of an official estimate of the amount required to carry on the business of the department in the forthcoming financial year. The British financial year begins in April and ends in March, so that the estimates for the financial year 1929–30 have to be prepared early in 1929.

The estimate of each department is called for by the Treasury, which on Oct. 1 of each year sends a request for the statement to each department concerned. As the period to which the estimate relates begins in the following April, the Treasury request is thus made six months in advance. These estimates are carefully checked by the Treasury, whose officials scrutinize them and compare carefully item by item with the expenditures of former years. The estimates receive more than civil service criticism. The chancellor of the exchequer for the time being is by virtue of his office anxious to keep down expenditure, for additions to expenditure make difficulties for him and compel him, unless revenue on the basis of existing taxation is swelling or likely to swell, to proceed to the unpopular task of imposing new taxation.

If any spending department of State furnishes to the Treasury estimates in which fresh items appear, or in which old items show considerable increases, the Treasury in such case returns the estimate to the issuing department with a request for explanation, or even with a demand for reduction. Thus in the first place the estimates of the British spending departments have to seek and gain acceptance by the Treasury. That is a cardinal principle of British national finance, and it casts a peculiarly onerous responsibility upon the Treasury, and upon its political chief, the chancellor of the exchequer, who is recognized as the first lieutenant of the British prime minister. When the chancellor of the exchequer rises in the House of Commons to announce the details of his budget, he has in effect made himself responsible for the presentation to parliament of reasonable estimates.

It is not always easy for a spending department to estimate in advance the sums it will require to carry on its business during a period which begins six months after the Treasury demands its figures, and ends 18 months after that demand is made and in cases requiring additional expenditure a supplementary estimate has to be submitted for the approval of the Treasury in the same manner as the estimates of the year. The outbreak of war, for example, or such a matter as the China Expeditionary Force of 1926–27 may cause a big supplementary estimate to be presented.

The British spending departments are: (1) the army, (2) the navy, (3) the air force, and (4) the big group known as the civil service. The estimates of the army, navy and air force concern matters of high policy, and the Treasury officials can do little with them. The civil service estimates concern many categories, including public works, civil departments, salaries and expenses, administration of law, education, foreign and colonial services, national insurance, labour exchanges, etc. In addition, there are the departments producing revenue, viz., customs and excise, inland revenue, and the post office.

The post office brings into the British revenue much more than it costs to run. Nevertheless, the estimates presented by the post office include the gross outgoings, although the whole of these outgoings are actually much less than is received by the post office in the course of the year. This manner of presenting the accounts always makes the national expenditure look larger than it really is.

The estimates, as sanctioned by the Treasury, are printed and placed before the House of Commons in the form of small booklets, in which the figures asked for are compared with those of the previous year and details given of any sums, such as fees, etc., received by the department in the course of its work and not paid into the revenue (*see* APPROPRIATIONS IN AID). The House of Commons possesses the constitutional right to criticize every estimate submitted to it, but in practice this right is largely curtailed by the exigencies of government. Thoroughly to debate even the main items in the estimates would take up the greater part of the time of the British parliament, which has never yet simplified the subject by referring such estimates to a special committee. It is true that the estimates are technically considered in committee, but that committee, the "committee of supply" is nothing more or less than the entire House of Commons sitting as a committee, with the Speaker out of the chair and the mace under the table.

With the great growth of parliamentary business in the latter part of the 19th century and the beginning of the 20th century, the parliamentary time given to the discussion of the estimates was contracted and reduced to 20 allotted days. So that the Government of the day should not be freed from criticism, however, it is the British constitutional practice to give the Opposition the right to name what estimates they wish discussed on each of the allotted days. The value of this provision lies in the fact that

if any particular spending department is thought to be misbehaving itself in administration, the Opposition has the opportunity to call the conduct of the department in question by calling for the discussion of its particular estimates. The constitutional form used is that the Opposition puts down an amendment to the vote of supply proposing to reduce it by £100. (*See* BUDGET; PARLIAMENT; EXCHEQUER.)

ESTON, urban district, Cleveland parliamentary division, North Riding of Yorkshire, England, 4 m. E.S.E. of Middlesbrough, on a branch of the L.N.E. railway. Pop. (1921), 30,635. It is situated at an altitude of between 100 and 150 ft. at the foot of the north-westward facing scarp of Eston Beacon (1,800 ft.). This is one of the principal centres from which the great ironstone deposits of the Cleveland hills are worked, and there are extensive blast furnaces, iron-foundries and steam saw-mills in the district. Numerous early earthworks fringe the hills to the south. Morton, 3 m. S.W. of Eston, was the birthplace of Captain Cook (1728).

ESTONIA, independent republic created February 1918, extending from 57° 27′ N. to 59° 42′ N. and from 21° 46′ E. to 28° 21′ E.: bounded north by the Gulf of Finland, west by the Baltic sea and the Gulf of Riga, south by Latvia and east by Russia. Area 47,559 sq.km. (2,328 sq.km. occupied by 1,512 lakes and 4,167 sq.km. by 818 islands); Saaremaa (Osel), Hiiumaa (Dagö), Muhumaa (Moon) and Vormsi (Vorms) are its largest islands. The coast is low and the greatest elevation is 450 ft. Moraines cover the surface and are thickest in the south and south-east. They rest on the Devonian in the south and on the Silurian in the north; beneath are Cambrian strata appearing in the cliffs as limestone, sandstone or oilshale. On the islands and in northern Estonia the limestone plain prevails. The river beds are shallow, there is much spring flooding, also bog land from which peat is obtained. The climate is continental save near the sea. The annual precipitation is 535 mm. of which about 25% is snow, which falls between November and April, August has most rain and December most snow. The prevailing winds are south-west and west. Two-thirds of the land (one-third meadow and pasture), is under cultivation. Cattle breeding is increasing at the expense of grain cultivation. Winter rye is the most important crop; summer rye and winter and summer wheat, buckwheat, peas, beans, lentils and forage for cattle food, including root crops are also produced. Potato cultivation is diminishing with less demand for potato spirit. Flax is increasingly grown, the fibre is exported and oil cake is used for cattle food. Dairy products have nearly doubled since 1922 and the number of horses, cows, sheep and pigs is much larger than in pre-war times. Forests of fir, pine, birch, aspen and alder, cover 20% of the land, mainly in the south-west and north-east. Of the timber cut 35% is exported, partly as planks, pit-props and sleepers and partly as finished wooden articles. The largest pulp mill in Estonia was destroyed by the Russian army and has not been rebuilt, but there are about 60 small paper and cardboard factories. Under war conditions, industrial capital was lost, plant and buildings destroyed and skilled workers dispersed. Metal industry, including shipbuilding, manufacture of agricultural implements, electrical apparatus, small wares, etc., is still small, but cotton, linen and woollen manufactures have become important exports; stone and chemicals are also exported. Oil shale began to be exploited for fuel in 1919 when 9,648 tons of oil were extracted. In 1925 production reached 287,000 tons, and since 1925 all railways use it. The cotton and paper mills work on hydro-electric power. Phosphorite fertiliser is worked from the lower Silurian beds. The trade turnover is increasing and there is a satisfactory balance. Textiles and dairy produce come next to timber and timber products in exports, raw cotton is the chief import. Germany, Great Britain and Russia take most of the exports and Germany, U.S.A. and Great Britain provide most of the imports. Transit trade from Russia is increasingly small. Estonia is essentially a maritime country and Tallinn (Revel), its chief port, and capital city, pop. (1926) 127,000, is open all the year, though in some years ice-breakers are temporarily necessary. East of Tallinn the Gulf of Finland is difficult through drift ice; the Gulf of Riga is frozen for 60 to 90 days per annum. Paldiski (Baltic port) is also open and with the help of ice-breakers ships can usually reach Pärnu and Narva-Joësuu (Hungerburg, chief timber port). River communication is poor. Tallinn is connected with Latvia and Russia by broad gauge railways; a branch to Pärnu was constructed in 1927. There are narrow gauge railways.

BY COURTESY OF THE Y.W.C.A.
WOMAN OF ESTONIA, IN NATIVE DRESS

The Esths or Estonians, who call themselves *Tallopoeg* and *Maames*, were known to the Russians as *Chukhni*, to the Letts as *Iggauni* and to the Finns as *Virolaiset*. They are of Finnish or Ural-Altaic extraction and resemble Finns (*q.v.*) physically. Since 1873 an Estonian Literary Society has helped to preserve the language, of which there are three dialects, Tartu, Tallinn and Pärnu. A Lutheran catechism was published in Estonian in the 16th century and a translation of the New Testament in 1713. National Songs resembling the Finnish Kalevala (*q.v.*) were collected and published by Kreutswald (1857). All children of eight must attend school until they have completed a four years' course or until they are fifteen; poor children are given books, clothing and footwear. The population in 1925 was 1,114,630, 87·7% Estonians, 8·2% Russians, 1·7% Germans, 0·7% Swedes and 1·6% other nationalities. Children of non-Estonian nationality receive instruction in their own language. Secondary schools provide 25% of free places, and completion of the course gives entrance to Tartu University, Tallinn Technical Institute, Tallinn Economic College, the Conservatoires at Tallinn and Tartu and the Art School at Tartu, without examination. There are technical, agricultural, commercial and naval schools. There are the Estonian Literary Society and scientific societies and a National Museum near Tartu. The library of Tartu University contains important manuscripts, with a special Arabic section. There is no national church, but 78% of the population are Lutherans and 18·8% Greek-Orthodox.

Language.—The Estonian language belongs to the west-Finnish group of the Finno-Ugrian family. Its nearest relatives are Finnish and Livian, Vepse, Votyak, etc. The east-Finnish group (Mordvinian, Syrjenian, Vogulian, etc.) represents an extra-European ramification of the family, of which Hungarian (Magyar) and Estonian are noteworthy examples. The nearness of Estonian to Finnish is as the relation between German and Danish, or Russian and Polish. The language is spoken by nearly 1,500,000 people.

The basis and structure of the language has not departed very far from Finnish, and many problems of early Finnish philology can be solved by reference to current Estonian words. From its position, however, the language has been subject to the influx of vocabulary from foreign tongues, the chief loan-words coming from Lithuanian, Gothic and the Slav languages.

There are two main spoken dialects included in the three mentioned above, the northern or "Revel-speech" and the southern, but the written language follows the northern phonology and spelling, and this has become the standard. The alphabet has 23 letters, the others (c. f. q. w. x. y. z) only appearing in foreign words. It is a highly inflected language, having a noun-declension of 16 cases.

The pronouns are declined through the same cases and the verb-system is very complicated. The pronouns are numerous and undergo declension. These declensions are of two kinds, strong and weak. The termination for weak declensions in the singular is *-d*, plural *-de* and *-id*.

The numerals present an interesting feature and from one to ten they are

1 *üks*, 2 *kaks*, 3 *kolm*, 4 *neli*, 5 *viis*, 6 *kuus*, 7 *seitse*, 8 *kaheksa*, 9 *üheksa*, 10 *kümme*.

Even these are declined (generally through seven cases) and ordinals and fractions are regularly formed from the cardinal

numbers. The stress accent is always on the first syllable of the word, and the laws of letter-attraction operate here as in other Finno-Ugric languages. The pronunciation is simple.

Administration.—Estonia is an independent republic with a representative assembly of 100 members elected by universal secret suffrage on the principle of proportional representation. There is complete freedom of conscience and no censorship of the press. Every citizen over 20 is enfranchised after one year's Estonian citizenship, with the exception of criminals, lunatics, deaf-mutes, etc. Insurance against sickness is compulsory and the state provides temporary occupation for the unemployed. All persons over 60 years of age receive relief if necessary and there are 46 government homes for children in need. The curative mud of the shallow seas has developed health resorts which attract foreign as well as local patients.

See M. Haltenberger, *Landeskunde von Esti* (Tartu, 1926); E. Vesterinen, *Agricultural Conditions in Estonia* (Helsinki, 1923); *Mémoire sur l'indépendance de l'Estonie, presenté à la Conférence de la Paix par la Délegation estonienne* (1919); J. P. Parikas, *Eesti* (Illustrated Handbook in several languages) Tallinn (1923).

Defence.—The formation of a national army in Estonia, impossible under the rule of the tsar, began in March 1917. In April the 2nd Tallin Regiment was allowed to enlist only Estonians. After invading the country, the German authorities, in Nov. 1918, ceded their power to the Estonian Provisional Government, which formed a Defence League at once. During the World War Estonians of mature age saw much military service, which was of value when repelling a Russian invasion of 1918–19, when assistance was given to Estonia by Finland in repelling the invaders, the result being the recognition by the Russian Republic in Feb. 1920 of the independence of Estonia.

Every Estonian is liable for military service, commencing in the year following his 20th birthday. This service is in four stages, service in the active army for 18 months, followed by furlough, by service in the reserve, and in the Territorial force. The total period in the active army and first reserve is five years. Service in the Territorial forces lasts until the age of 55, in the active army and its reserves till 45. The budget strength of all ranks in 1927 was 17,340, including 1,500 military officers and officials. The army is organized nominally in three divisions of infantry and artillery, and one for air-defence and coast defence, which includes armoured cars and tanks, and armoured trains. The Government commands the army through the minister of war, who has under him the chief of staff of the army, with inspectors of the various arms, and the general staff, which is charged with administrative as well as with the usual duties. The division of armoured troops is of interest. It comprises two companies of tanks, one company of armoured cars, one of motor vehicles, and a stores company. There is a military air-force, organized as an air regiment, including a land service aviation group of two flights and a training flight, also a seaplane flight, a training section, and a technical section.

See also *The Estonian Handbook* (1927); League of Nations *Armaments Yearbook* (1928). (G. G. A.)

Navy.—The navy of Estonia is a miniature force consisting of two destroyers, both ex-Russian ships, one torpedo boat and seven miscellaneous vessels, gunboats, minelayers, etc. It is administrated by a combined Ministry of War. The personnel consists of about 1,500 officers and men.

THE PROBLEM OF RECONSTRUCTION

Before the World War Estonia was one of the principal sources of food supply for St. Petersburg (now Leningrad), and Revel was one of Russia's main northern outlets to the sea and a seat of considerable industry—shipbuilding, metallurgical shops, textile mills, etc.

The problem of reconstruction with which the government was faced after the Treaty of Dorpat was extremely difficult. An agricultural revolution had been created by the expropriation law of Oct. 1919. The big industries were destitute of floating capital after six years of inflation. The whole machinery of government and administration had to be reorganized and built up from its foundations.

Agriculture.—The most essential task was the reorganization of agriculture. About 40% of the total area consists of prairie and meadow, 23% is under plough, and 20% under forest. With the assistance of co-operative societies, Estonian agriculture was developed on specialist lines in cattle-breeding, dairy-farming, and flax production. The total exports of butter, which is controlled by the state, increased from 1,032 tons in 1922 to 6,443 tons in 1925.

The areas under cereals and average cereal crops are about the same as they were before the World War, and Estonia remains a corn-importing country. The area under flax has grown steadily from year to year.

Industrial Production.—Estonia possesses certain raw materials, the most important of which are wood and oil shale. The shale, the deposits of which are roughly estimated at 3,500–5,000 million tons, is unusually rich in oil. It is utilized to a growing extent in Estonian factories and on the railways in its crude state in place of coal. A certain number of concessions for its more scientific exploitation have been granted to foreign firms.

The forests constitute an additional source of fuel and the raw material of the saw mills, three-ply, and paper industries. Cement is another product, the preparation of which is in no way dependent upon foreign raw materials. Of the industries which are dependent upon foreign raw materials cotton spinning has been the most successfully organized, the exports of cotton yarn having increased from 154 tons in 1922 to 1,282 in 1925.

Trade.—The principal exports of the country in 1925 were:—

	Value in millions of Estonian marks.
Dairy produce and other foodstuffs of animal origin	2,557
Wood and wood products	2,729
Cotton fabrics	1,094
Flax, raw	1,286
The total exports amounted to	9,664

Although Estonia was the first "window into Europe" for Soviet Russia, neither Russian transit nor the traffic in goods attained the height reached before the World War. (X.)

HISTORY

The Estonians first appear in history as a warlike race. More than one of the Danish kings made serious attempts to subdue them. In 1219 Waldemar II. undertook a crusade against them, in the course of which he founded the town and episcopal see of Revel. By his efforts the northern portion of the race were made submissive to the Danish crown; but, though conquered, they were incessantly in revolt, until in 1346, after a great rebellion in 1343, Waldemar IV. Atterdag sold for 19,000 marks his portion of Estonia, to the order of the Knights of the Sword, German crusaders who in 1224, after a quarter of a century's fighting had gained possession of the regions inhabited by the southern portion of the race. From that time for nearly 600 years the Estonians were practically reduced to a state of serfdom to the German landowners. In 1521 the nobles and cities of Estonia voluntarily placed themselves under the protection of the crown of Sweden; but after the wars of Charles XII., Estonia was formally ceded to his victorious rival, Peter the Great, by the peace of Nystad (1721). Serfdom was abolished in 1817 by Tsar Alexander I.; but the condition of the peasants was so little improved that they rose in open revolt many times in the middle of the 19th century. The determining feature of their history since 1881 was the attempt made by the Russian Government to russify the inhabitants of the province by harsh and repressive measures.

The Russian Revolution.—Acting on the proposal of the union of Estonian organizations, the Russian provisional Government, on March 12, 1917, united the northern districts of Livonia (inhabited by Estonians) and Estonia. Since the revolution of 1905 Estonia had been working for autonomy and when the Estonian diet met at Revel (Tallinn) on July 14, 1917, its task was to prepare a bill for this purpose. The Bolshevist *coup d'état* changed the course of events. The Estonian diet, on Nov. 15, declared its complete local independence. The Bolshevists, how-

ever, dissolved the diet; and although national regiments had been formed during the revolution, the fact that Revel was the Russian sea base, and lay exposed to fire from Russian ships, made it expedient to avoid conflict. The Baltic nobility of Estonia, taking their stand on the Treaty of Nystad (1721), declared themselves the authorized representatives of the country, and on Dec. 12, 1917, invoked the aid of German troops. The nobility approached the Estonian diet with the object of securing a joint appeal to Germany; but the diet, well aware of their schemes for German colonization and compulsory denationalization, decided, at the turn of the year 1917–18 to declare the independence of Estonia.

De Facto Recognition.—The resumption of hostilities by the Germans had disconcerted the Bolshevists, and advantage was taken of this fact to overthrow the Bolshevist rule at Revel and proclaim Estonia an independent republic on Feb. 24, 1918. The resolution of the diet was laid before the Allied Governments; favourable replies were received, the *de facto* recognition of Estonia by Great Britain, France and Italy following on May 3, May 13 and May 29 respectively.

The subsequent German occupation was designed to turn Estonia into a Baltic duchy in personal union with Prussia, in conformity with the wishes of the Baltic nobility; but although the representatives of the Estonian peasant-proprietors, when summoned to the Riga Assembly on April 10, 1918, refused their consent, Baron Dellingshausen, the leader of the Baltic nobility, forwarded the request for union with Prussia to Berlin, and received the German Emperor's consent on April 21, 1918. After the peace of Brest-Litovsk (*see* BREST-LITOVSK, TREATIES OF) Soviet Russia renounced her sovereign rights over Estonia by the supplementary agreement of Berlin on Aug. 27, 1918. With the collapse of Germany the Estonian provisional Government resumed its activities. K. Pats, the former president of the diet, released from imprisonment by the Germans, became Prime Minister; and J. Poska foreign minister.

The Bolshevik Invasion.—The German troops had not been completely withdrawn before a new danger threatened from the east. Narwa had been invested by the Bolshevists, who began to penetrate into Estonia (Nov. 28), aided by landings on the coast of the Gulf of Finland. Estonia's situation was rendered difficult by the fact that the Germans had removed all arms. Out of the cadres of the Estonian regiments of 1917 Gen. Laidoner had begun to organize an Estonian army, while Capt. J. Pitka created a marine force of volunteers and students, forming shock battalions and improvising armoured trains out of goods trucks. Assistance came first in the form of a loan amounting to 20,000,000 Finnish marks, a consignment of arms and a body of over 2,000 volunteers from Estonia's sister-nation, Finland. On Dec. 12, 1918, a British fleet under Admiral Sinclair arrived at Revel, which brought over a supply of arms and took the Gulf of Finland under its protection. Sinclair captured two Russian destroyers and handed them over to Estonia. On Jan. 4, 1919, when the Bolshevists held half Estonia in their grasp, their offensive was broken, and by the beginning of February the whole country was freed. The Constituent Assembly voted unanimously for independence, and formed a coalition Government.

Throughout the spring, Bolshevik attacks continued. In May, the Estonians took the offensive, carrying operations over into Russian territory. The "Northern Corps" of the Russian White Army under Gen. Rodzianko, which had retired into Estonia from Pskov, occupied Yamburg, the Estonians taking Pskov. As the result of an attack to the south, Northern Latvia was freed from the Bolshevists. In the neighbourhood of Riga an encounter occurred with Gen. R. von der Goltz's German volunteers, who had overthrown the Lettish democratic Government at Libau. Gen. Sir H. Gough, as chief of the Allied military mission, had ruled, in support of the demand of the Estonians, that von der Goltz should not lead his troops against Estonia. In defiance of this, von der Goltz broke the armistice, but on June 21–22, at the battle of Wenden-Ronneburg his army was put to flight and driven out of Northern Latvia. By the intervention of the Allies a new armistice was concluded at Riga on July 3, 1919, and von der Goltz was forced to evacuate.

Peace with Russia.—As neither the White Russians nor the Paris peace conference of the Allies would acknowledge her *de jure*, Estonia, on Aug. 31, accepted the peace proposals made by Soviet Russia. On Dec. 5, 1919, peace negotiations were opened at Dorpat. An armistice was declared on Dec. 31, and peace was concluded on Feb. 2, 1920. Russia agreed to acknowledge the independence of Estonia and to pay her 15,000,000 gold roubles (£1,500,000) from the Russian gold fund, but refused to return the funds, savings and money which had been removed. On the other hand, Estonia was released from any responsibility for Russia's debts abroad. Free transit to Estonian ports was conceded to Russia. This was the first peace treaty concluded between Soviet Russia and any of the border states.

Currency.—The economic progress which the country has achieved may be judged from the growth of its total exports from 2,287 million Estonian marks in 1921 to 9,637 million in 1926. Direct fiduciary inflation ceased in 1921, and the exchange improved slightly during the next two years. With the bank inflation of 1923–24 the exchange depreciated from about 340 to 460 (Aug. 1924) to the dollar. By the end of the year, however, the central bank, which is a government institution, had succeeded in bringing down the rate to about 373 Estonian marks to the dollar. The exchanges were kept stable at this rate from Jan. 1925 onwards, and it is proposed to introduce a new currency, a Kroon, equivalent to 100 of the present Estonian marks.

The measure of success with which Estonia has met her economic reconstruction, despite great initial difficulties, and despite inevitable errors, has been largely due to the fact that since 1921 she has managed to balance her budget. Indeed, not only has the budget been balanced, but the capital outlay incidental upon her economic reconstruction has been largely met out of current revenues. Her taxes have thus been to a considerable extent a form of forced savings.

Démographie* (Revel, 1924); League of Nations, *Report of the Financial Committee on the economic and financial situation of Estonia* (Geneva, 1925). Estonian Year Books. (E. LA.)

Internal Affairs.—On Oct. 10, 1919, while the war was still in progress, the Estonian Constituent Assembly had passed an Agrarian Reform bill, by which manorial estates of more than 330 hectares, a type of holding which covered more than half of the whole agricultural area, were to be divided in holdings averaging from 20 to 25 hectares. Thus the landless peasant population was satisfied. The last task of the Constituent Assembly was the adoption (June 15, 1920) of a democratic constitution providing for a Republican Government, with parliament (Riigikogu) consisting of 100 members elected by universal and secret ballot on the proportional representation system. Direct exercise of power by the people is provided through initiative and referendum. The prime minister is the head of the state.

When the civil war in Russia ended the Supreme Council of the Allies agreed to the *de jure* recognition of Estonia (Jan. 26, 1921). On Sept. 22 of the same year Estonia was admitted to the League of Nations. Recognition by the United States followed on July 28, 1922.

Estonia was the last of the border states to declare the Communist party illegal (autumn, 1923). At Revel a *putsch* was attempted early in the morning of Dec. 1, 1924. About 300 conspirators, composed partly of Russian red guards and Russian transit workers in Revel, provided with arms secretly imported from Russia, made a sudden and simultaneous attack on the Government and military institutions, but were immediately repulsed. The result of this revolutionary outburst was the closing of all Communist organizations and the founding of civil guards on the Finnish model, in which 30,000 men were enrolled. The Communist movement in Estonia became virtually extinct and relations with the Soviet Union acquired a more peaceful character, and finally negotiations for a non-aggression treaty became possible. Besides this Communist outburst, the German crisis of 1923 produced a financial depression, which, however, was soon

overcome. In order to facilitate the reform of the central note bank and the creation of a currency on gold basis, the Council of the League of Nations guaranteed through a Protocol, signed in Geneva on Dec. 10, 1926, an international loan of £1,350,000 net.

By 1927 the agrarian reform was almost completely realized. A law providing compensation for the nationalized estates was passed on March 5, 1926, and the petition of the expropriated German landowners, who were not satisfied with the compensation, was declined by the Council of the League on June 15, 1927. The status of the national minorities, who constitute 12·3 per cent. of the entire population, was determined by the law of Feb. 5, 1925, which guaranteed them complete cultural autonomy.

Foreign Policy.—Attempts to co-ordinate the foreign policy of the Baltic States had been made while they were still fighting for independence. At Warsaw, on March 17, 1922, Estonia, Poland, Latvia and Finland signed a political agreement, which, however, did not come into force, Finland refusing to ratify it on the ground that it might be directed against Germany. In 1925, an agreement was reached between the Baltic States for the establishment of a permanent court of arbitration. Estonia came to a final agreement with Latvia on Nov. 1, 1923, when a treaty of defensive alliance was concluded and an economic agreement signed. The economic clauses, which established unified tariffs and duty-free transit of goods, marked the first step in the direction of a complete customs union.

ESTOPPEL, a rule in the law of evidence by which a party in litigation is prohibited from asserting or denying some alleged fact. Estoppel is said to arise in three ways—(1) by record or judgment, (2) by deed, and (3) by matter *in pais* or conduct. (1) Where a cause of action has been tried and final judgment has been pronounced, the judgment is conclusive—either party attempting to renew the litigation by a new action would be estopped by the judgment. (2) "A man shall always be estopped by his own deed, or not permitted to aver or prove anything in contradiction to what he has once so solemnly and deliberately avowed" (Blackstone, 2 *Com.* 295). (3) Estoppel by conduct is the most important head. The rule practically comes to this that, when a person in his dealings with another has so acted as to induce him to believe a thing to be true and to act on such belief, the former may not deny the thing to be true to the detriment of the latter in any proceeding between them; *e.g.*, a partner retiring from a firm without giving notice to the customers, cannot, as against a customer having no knowledge of his retirement, deny that he is a partner. As between landlord and tenant the principle operates to prevent the denial by the tenant of the landlord's title. Again, if a man accepts a bill of exchange he may not deny the signature or the capacity of the drawer. So a person receiving goods as baillee from another cannot deny the title of that other to the goods at the time they were entrusted to him. A person cannot, however, be prevented from denying the actuality of what he cannot legally do; for example, a corporation is not estopped as to acts which would be *ultra vires*. *See* EVIDENCE.

See L. F. Everest and E. Strode, *The Law of Estoppel* (1884); M. Cababé, *Principles of Estoppel* (1888).

ESTOUTEVILLE, GUILLAUME D' (1403–1483), French ecclesiastic, archbishop of Rouen, was sent to France as legate by Pope Nicholas V. to make peace between Charles VII. and England (1451), and undertook, *ex officio*, the revision of the trial of Joan of Arc; he afterwards reformed the statutes of the University of Paris. He then went to preside over the assembly of clergy which met at Bourges to discuss the observation of the Pragmatic Sanction (*see* BASEL, COUNCIL OF), finally returning to Rome, where he passed almost all the rest of his life. He was a great builder, Rouen, Mont St. Michel, Pontoise and Gaillon owing many noble buildings to his initiative.

ESTOVERS, a term in English law for the wood which a tenant for life or years may take from the land he holds for repair of his house, the implements of husbandry, and the hedges and fences, and for firewood. The O.E. word for estover was *bote* or *boot* (*q.v.*). These rights may of course be restricted by express covenants. Copyholders had similar rights over the land they occupied and over the waste of the manor, in which case they were known as "Commons of estovers." (*See* COMMONS.)

ESTRADA, LA, a town of north-western Spain, province of Pontevedra, 7 m. E. of Requeijo, its nearest station, on the Pontevedra-Santiago railway. Pop. (1920) 25,471. La Estrada is the chief town of a populous mountain district, producing maize, wheat, barley, potatoes, fruit, cattle and pigs. Leather and linen paper are manufactured in the town, and lumber from the mountain forests is floated down the river Ulla, 4 m. N., to the seaports on Arosa bay. There are mineral springs at La Estrada and at Caldas de Reyes, 11 m. W.S.W.

ESTRADES, GODEFROI, COMTE D' (1607–1686), French diplomatist and marshal, was born at Agen. He was the son of François d'Estrades (d. 1653), a partisan of Henry IV., and brother of Jean d'Estrades, bishop of Condom. In 1646 he was named ambassador extraordinary to Holland, and took part in the conferences at Münster. Sent in 1661 to England, he obtained in 1662 the restitution of Dunkirk. In 1667 he negotiated the treaty of Breda with the king of Denmark, and in 1678 the treaty of Nijmwegen, which ended the war with Holland. He took part in the principal campaigns of Louis XIV., in Italy (1648), in Catalonia (1655), in Holland (1672); and was created marshal of France in 1675. His *Lettres, mémoires et négociations en qualité d'ambassadeur en Hollande depuis 1663 jusqu' en 1668,* were posthumously published in 1709.

Of the sons of Godefroi d'Estrades, Jean François d'Estrades was ambassador to Venice and Piedmont; Louis, marquis d'Estrades (d. 1711), succeeded his father as governor of Dunkirk, and was the father of Godefroi Louis, comte d'Estrades, lieutenant-general, who was killed at the siege of Belgrade, 1717.

See Felix Salomon, *Frankreichs Beziehungen zu dem Scottischen Aufstand* (1637–1640), containing an excursus on the falsification of the letters of the comte d'Estrades; Philippe Lauzun, *Le Maréchal d'Estrades* (Agen, 1896).

ESTREAT, originally, a true copy or duplicate of some original writing or record; now used only with reference to the enforcement of a forfeited recognizance. At one time it was the practice to extract and certify into the Exchequer copies of entries in court rolls which contained provisions or orders in favour of the Treasury; hence the estreating of a recognizance was the taking out from among the other records of the court in which it was filed, sending it to the Exchequer to be enforced, or sending it to the sheriff to be levied by him, and then returned by the clerk of the peace to the lords of the Treasury. (*See* RECOGNIZANCE.)

ESTRÉES, GABRIELLE D' (1573–1599), mistress of Henry IV. of France, was the daughter of Antoine d'Estrées, marquis of Coeuvres, and Françoise Babou de la Bourdaisière. Henry IV., who in Nov. 1590 stayed at the castle of Coeuvres, became violently enamoured of her. Her father married her to Nicholas d'Amerval, seigneur de Liancourt, but in Dec. 1592, Gabrielle, whose affection for the king was sincere, became his mistress. She lived with him from Dec. 1592 onwards, and bore him several children, who were recognized and legitimized by him. She possessed the king's entire confidence; he willingly listened to her advice, and created her marchioness of Monceaux, duchess of Beaufort (1597) and Étampes (1598), a peeress of France. The king even proposed to marry her in the event of the success of his suit for the nullification by the Holy See of his marriage with Margaret of Valois; but before the question was settled Gabrielle died, on April 10, 1599. Poison was of course suspected; but her death was really caused by puerperal convulsions (*eclampsia*).

See *Gabrielle d'Estrées et la politique de Henri IV.* (1859); A. Desclozeaux, *Gabrielle d'Estrées, Marquise de Monceaux,* etc. (1889; Eng. trans. 1907).

ESTREMADURA or **EXTREMADURA,** an ancient territorial division of central and western Portugal, and of western Spain; comprising the modern districts of Leiria, Santarem and Lisbon, in Portugal, and the modern provinces of Badajoz and Cáceres in Spain. Pop. (1920) 2,662,782; area, 23,055 sq.m. The name of Estremadura appears to be of early Romance or Late Latin origin, and probably was applied to all the far western lands (*extrema ora*) bordering upon the lower Tagus, as far as the Atlantic ocean. It is thus equivalent to *Land's End,* or *Finisterre.*

1. Portuguese Estremadura is bounded on the N. by Beira, E. and S. by Alemtejo, and W. by the Atlantic ocean. Pop. (1920) 1,544,704; area, 6,937 sq.m. The greatest length of the province, from N. to S. is 165 m.; its greatest breadth, from E. to W., is 72 m. The general uniformity of the coast-line is broken by the broad and deep estuaries of the Tagus and the Sado, and by the four conspicuous promontories of Capes Carvoeiro, da Roca, Espichel and Sines. The Tagus is the great navigable waterway of Portuguese Estremadura, flowing from north-east to south-west, and fed by many minor tributaries, notably the Zezere. South of the Tagus the land is almost everywhere low, flat and monotonous. The Sado, which issues into Setubal Bay, is the only important river of this region. North of the Tagus, and parallel with its right bank, extends the mountain chain which is known at its northern extremity as the Serra da Aire and, where it terminates above Cape da Roca, as the Serra de Cintra. On its seaward side, except for the line of sheer and lofty cliffs between Cape Carvoeiro and Cape da Roca, the country is mostly flat and sandy, with extensive heaths and pine forests. The natural resources of Portuguese Estremadura, with its inhabitants, industries, commerce, communications, etc., are described under PORTUGAL. Separate articles are also devoted to Lisbon, the capital, and Abrantes, Cintra, Leiria, Mafra, Santarem, Setubal, Thomar, Torres Novas and Torres Vedras, the other chief towns. The women of Peniche, a small fishing village on the promontory of Cape Carvoeiro, have long been celebrated throughout Portugal for their skill in the manufacture of fine laces.

2. Spanish Extremadura is bounded on the N. by Leon and Old Castile, E. by New Castile, S. by Andalusia, and W. by the Portuguese province of Beira and Alemtejo, which separate it from Portuguese Estremadura. Pop. (1920) 1,118,078; area, 16,118 sq.m. Spanish Extremadura consists of a tableland separated from Leon and Old Castile by the lofty Sierra de Gredos, the plateau of Béjar and the Sierra de Gata, which form an almost continuous barrier along the northern frontier, with its summits ranging from 6,000 to more than 8,500 ft. in altitude. On the south the comparatively low range of the Sierra Morena constitutes the frontier of Andalusia; on the east and west there is a still more gradual transition to the plateau of New Castile and the central plains of Portugal. The tableland of Spanish Extremadura is itself bisected from east to west by a line of mountains, the Sierras of San Pedro, Montanchez and Guadalupe (4,000–6,000 ft.), which separate its northern half, drained by the river Tagus, from its southern half, drained by the Guadiana. The Tagus and Guadiana flow from east to west through a monotonous country, level or slightly undulating, often almost uninhabited, and covered with a thin growth of shrubs and grass. Perhaps the most characteristic feature of this tableland is the vast heaths of gum-cistus and lavender.

The climate in summer is hot but not unhealthy, except in the swamps which occur along the Guadiana. The soil is naturally fertile, but drought, floods and locusts render agriculture difficult, and sheep-farming is the most important of Extremaduran industries. (*See* SPAIN: *Agriculture.*)

Immense herds of swine are bred and constitute a great source of support to the inhabitants—the pork, bacon and hams being in high esteem. The beech, oak and chestnut woods afford an abundance of food for swine, and there are numerous plantations of olive, cork and fruit trees. *See* CÁCERES and BADAJOZ. In character and physical type, the people of this region are less easily classified than those of other Spanish provinces. Their failure to develop a distinctive local type of character and civilization is perhaps due to the adverse economic history of their country. The two great waterways which form the natural outlet for Estremaduran commerce flow to the Atlantic through a foreign and, for centuries, a hostile territory. Like other parts of Spain, Extremadura suffered severely from the expulsion of the Jews and Moors (1492–1610). Many ancient palaces at Trujillo and Cáceres recall the fact that Cortes (1485–1547), the conqueror of Mexico and Pizarro (*c.* 1471–1541), the conqueror of Peru, were both born in Estremadura, but their exploits, far from bringing permanent prosperity to their native province, only encouraged the emigration of its best inhabitants.

ESTREMOZ, a town of Portugal, 104 m. by rail E. of Lisbon, on the Casa Branca-Evora-Elvas railway. Pop. (1920) 8,591. Estremoz is built at the base of a hill crowned by a large dismantled citadel. There are marble quarries in the neighbourhood, and the Estremoz *bilhas,* red earthenware jars, are used throughout Portugal as water-holders and exported to Spain. At Ameixial (661) and Montes Claros, near Estremoz, the Spanish were severely defeated by the Portuguese in 1663 and 1665. Villa Viçosa (4,144), 10 m. S.E., is a town of pre-Roman origin, containing a royal palace.

ESTUARY, the mouth of a river where sea and fresh water meet and where tidal effects are conspicuous (Lat. *aestuarium,* a place reached by *aestus,* the tide). An estuary may result from the long-continued joint action of river and tidal erosion confined to a narrow structural depression, or an estuary may be the drowned lower portion of a river-valley. Isobaths are drawn to show sea-depths and the isobathic chart of the Severn estuary, for example, shows a progressive deepening seawards by means of V-shaped lines which become blunter westwards until the last one is a mere indentation pointing up channel; these lines may be indicative of the progress of the channel over the existing continental shelf. Where, as in the Severn and the Thames, the fresh water meets the sea gradually the water is thoroughly mixed, and there is very little change in salinity at high tide. The fresh water tends to flow over the denser salt water, but there is a continuous increase in salinity seawards, for the ebbing and flowing currents constantly mix the waters. On the other hand, where the river brings down a great quantity of fresh water into a narrow channel, the change of salinity from high to low water is very marked. Mill uses the Firth of Forth as an interesting example; here the landward half is a true estuary, but the seaward half has the water so thoroughly mixed that the salinity is almost uniform from surface to bottom, and increases but gradually towards the sea. In consequence, the Forth causes the sea to become slightly freshened throughout its whole depth for many miles from the land.

ESZTERGOM, a Hungarian town situated on a loess-covered terrace on the right bank of the Danube, nearly opposite its confluence with the Hron. Once the capital of Hungary and the site of its first church it is the seat of the primate of Hungary, but its chief claim to national importance lies in the fact that it was the birthplace of St. Stephen, the first "apostolic king" of Hungary. As one of the great centres of Magyar life it attracted the attention of the Mongols who destroyed it in 1241, but it was rebuilt and fortified by King Béla IV. Becoming thus a strong outer guard of Vienna the Turks attacked and held it for two periods, 1543–95 and 1604–83. During this time of stress the archbishopric, dating from 1001, was moved to Trnava (*q.v.*), where it remained till 1820. The cathedral on a hill 215 ft. above the river is a grandiose structure, erected 1821–70, on the lines of St. Peter's at Rome and contains in its treasury the 13th century Florentine Calvary of King Matthias and the double cross presented to King Stephen by Pope Silvester II. The town has many other churches and ecclesiastical buildings, including a beautiful primate's palace in Renaissance style, containing a rich collection of antiquities. The population is chiefly engaged in the weaving of cloth, wine-making and mixed farming. Pop. (1920) *c.* 20,000.

ÉTAGÈRE, a piece of light furniture very similar to the English what-not, which was extensively made in France during the latter part of the 18th century. As the name implies, it consists of a series of stages or shelves for the reception of ornaments or other small articles. Like the what-not it was very often corner-

wise in shape, and the best Louis XVI. examples in exotic woods are exceedingly graceful and elegant.

ETAH, a town and district of British India, in the Agra division of the United Provinces. The town is situated on the Grand Trunk road. Pop. (1921) 9,597. The district has an area of 1,720 sq.m. The district consists for the most part of an elevated alluvial plateau, dipping down on its eastern slope into the valley of the Ganges. The uplands are irrigated by the Ganges canal. Between the modern bed of the Ganges and its ancient channel lies a belt of fertile land, covered with a rich deposit of silt, and abundantly supplied with natural moisture. A long line of swamps and hollows still marks the former course of the river; and above it rises abruptly the original cliff which now forms the terrace of the upland plain. The neighbourhood of Etah is mentioned by Hsüan Tsang, the Chinese Buddhist pilgrim of the 7th century A.D., as rich in temples and monasteries. With the rest of upper India it passed under the sway of Mahmud of Ghazni in 1017, and thenceforth followed the fortunes of the Mohammedan empire. At the end of the 18th century it formed part of the territory over which the wazir of Oudh had made himself ruler, and it came into the possession of the British government in 1801, under the treaty of Lucknow. In 1921 the population was 829,760. There are cotton gins and presses at Kasganj (pop. 20,988) and Soron (pop. 10,175), which are the two chief trading centres of the district.

ÉTAMPES, ANNE DE PISSELEU D'HEILLY, Duchesse d' (1508–*c.* 1580), mistress of Francis I. of France, daughter of Guillaume of Pisseleu, sieur d'Heilly, a nobleman of Picardy. She was one of the maids of honour of Louise of Savoy. Francis I. made her his mistress, probably on his return from his captivity at Madrid (1526). In 1533 Francis gave her in marriage to Jean de Brosse, whom he created duc d'Étampes. The duchess upheld Admiral Chabot against the constable de Montmorency, who was supported by her rival, Diane de Poitiers, the dauphin's mistress. She was a friend to new ideas, and co-operated with the king's sister, Marguerite d'Angoulême. After the death of Francis I. (1547) she was dismissed from the court by Diane de Poitiers, and died in obscurity, probably in the reign of Henry III.

See Paulin Paris, *Études sur François Ier* (1885); E. Desjardins, *Anne de Pisseleu, Duchesse d'Étampes, et François Ier* (1904), which contains a bibliography.

ÉTAMPES, a town of northern France, capital of an arrondissement in the department of Seine-et-Oise, on the Orléans railway, 35 m. S. by W. of Paris. Pop. (1926) 9,411. Étampes (Lat. *Stampae*) existed at the beginning of the 7th century and in the early middle ages belonged to the crown domain. During the middle ages it was the scene of several councils, the most notable of which took place in 1130 and resulted in the recognition of Innocent II. as the legitimate pope. In 1652, during the war of the Fronde it suffered severely at the hands of the royal troops under Turenne. The lordship of Étampes, in what is now the department of Seine-et-Oise in France, belonged to the royal domain, but was detached from it on several occasions in favour of princes, or kings' favourites. St. Louis gave it to his mother Blanche of Castile, and then to his wife Marguerite of Provence. Louis, the brother of Philip the Fair, became Lord of Étampes in 1317 and count in 1327; he was succeeded by his son and grandson. Francis I. raised the countship of Étampes to the rank of a duchy for his mistress Anne de Pisseleu D'Heilly. The new duchy passed to Diane de Poitiers (1553), to Catherine of Lorraine, duchess of Montpensier (1578), to Marguerite of Valois (1582) and to Gabrielle d'Estrées (1598). The latter transmitted it to her son, César of Vendôme, and his descendants held it till 1712. It then passed to the families of Bourbon-Conti and of Orleans.

Étampes stretches between the railway on the north and the Chalouette, a tributary of the Juine, on the south. The Tour Guinette is a ruined keep built by Louis VI. in the 12th century. Notre-Dame du Fort (11th and 12th centuries), the chief church, is irregular in plan, with a fine Romanesque tower and spire, and a crenellated wall. The interior contains ancient paintings. St. Basile (12th and 16th centuries) preserves a Romanesque doorway, and St. Martin (12th and 13th centuries) a 16th century leaning tower. Two houses named after Anne de Pisseleu (*see* above), mistress of Francis I., and Diane de Poitiers, mistress of Henry II., are graceful examples of Renaissance architecture. There are a subprefecture and a tribunal of first instance. Flour-milling, printing and manufacture of hosiery are carried on.

ÉTAPLES, a town of northern France, in the department of Pas-de-Calais, on the right bank of the estuary of the Canche, 3 m. from the Straits of Dover, 17 m. S. of Boulogne by rail. Pop. (1926) 6,423. Étaples was a small fishing and commercial port, important during the middle ages. Boat-building is carried on. Le Touquet, in the midst of pine woods, and the neighbouring Paris-Plage, 3½ m. W. of Étaples at the mouth of the estuary, are much frequented watering places. Antiquarian discoveries have led to the conjecture that Étaples occupies the site of the Gallo-Roman port of *Quentovicus.* In 1492 a treaty was signed here between Henry VII., of England, and Charles VIII., of France. The town was used by the British in the World War.

ETAWAH, a town and district of British India, in the Agra division of the United Provinces. The town is situated on the left bank of the Jumna. Pop. (1921) 41,558. Deep fissures intersect the various quarters of the town, over which broad roads connect the higher portions by bridges and embankments. The Jamma Musjid (Great Mosque) is the chief architectural ornament of Etawah. It was originally a Hindu temple, and was adapted to its present use by the Mohammedan conquerors. Several fine Hindu temples also stand about the mound on which are the ruins of the ancient fort. The manufactures include cotton cloth, skin-bottles, combs and horn-ware.

The District of Etawah has an area of 1,691 sq.m., stretching across the level plain of the Doab, and beyond the valley of the Jumna, to the gorges of the Chambal, and the last rocky outliers of the Vindhyan range. The district exhibits a striking variety of surface and scenery. In the Doab portion the tract to the north-east of the river Sengar is rich and fertile, being watered by the Ganges canal; across the Sengar there is no canal and less fertility. Near the banks of the Jumna, the plain descends into the river valley by a series of wild ravines and terraces, inhabited only by a scattered race of hereditary herdsmen. Beyond the Jumna again a strip of British territory extends along the tangled gorges of the Chambal and the Kuari Nadi, far into the borders of the Gwalior state. Important experiments have been made in reclaiming ravines and afforestation.

Etawah was marked out by its physical features as a secure retreat for the turbulent tribes of the Upper Doab, and it was not till the 12th century that any of the existing castes settled on the soil. After the Mohammedan conquests of Delhi and the surrounding country, the Hindus of Etawah appear to have held their own for many generations against the Mohammedan power; but in the 16th century Baber conquered the district with the rest of the Doab, and it remained in the hands of the Moguls until the decay of their empire. After passing through the usual vicissitudes of Mahratta and Jat conquests during the long anarchy which preceded the British rule, Etawah was annexed by the wazir of Oudh in 1773, and ceded to the East India Company in 1801. In 1921 the population was 733,532.

ETCHING is the process of biting lines or areas by means of acid or some other chemical. By etching generally we mean the process of biting these lines in a metal plate with a view to its being printed from, and by an etching, the print taken from a plate so etched. Lines may indeed be etched on a metal plate which is itself intended to serve some decorative purpose, with no idea of prints being taken from it, but etching of this sort should more properly be treated in connection with decorative metal work and has no significance here. Etching, as above defined, has this important point in common with line engraving, that the lines which are to appear black on the print are incised as opposed to those in wood engraving which are in relief. The process of printing from an etched plate is, therefore, identical with that of printing from an engraved plate. Etching only differs from line engraving in the process by which the lines are incised; in the latter case, by an instrument of triangular section which scoops a shaving out of the metal; in the former, by chemical

action. A print from an etched plate may generally be distinguished from a print from an engraved plate, by the fact that in the former the lines do not diminish or increase gradually in thickness but do so in more or less abrupt stages; that the endings of the lines are square, whereas in the latter they taper gradually to an end. These differences are inherent in the different processes. It is obviously impossible to end a line abruptly by means of a triangular gouging instrument, such as a burin; if the burin were stopped suddenly the shaving it forms in its course would be left. In etching, on the other hand, the thickness or thinness of the lines being obtained by successive bitings and each successive biting being comparatively uniform over the plate, a line, which is intended to gradually diminish in size, has (microscopically perhaps) a form like that of an extended telescope. Engraving has, of course, been constantly used in combination with etching and it is often a matter of difficulty to distinguish between the parts which are purely etched, those which have been first etched and later strengthened by the engraving tool and those which have been directly engraved. A further word should be added on the subject of dry-point. This is merely the process of scratching with the etching needle direct on the plate. In its passage the needle leaves an irregular ridge on either side of the line which it makes (burr) to which the ink adheres, so that a dry-point line when printed has at first a slightly blurred, but rich effect: this burr wears away quickly and the scratched line by itself, when printed, is then faint and meagre. Dry-point, though it is independent of the use of mordants, is generally employed in conjunction with etching for the richness of its effect.

The number of satisfactory prints which may be taken from an etched plate varies according to the hardness of the metal and the depth to which the lines have been etched. A fine line on a copper plate may be almost obliterated after 200 or 300 impressions: a dry-point line will, as has been indicated, lose its characteristic effect very much sooner. Some of the prints taken from Rembrandt's plates 50 years ago are almost, though not quite, as good as those taken during his lifetime.

HISTORY

Etching, like engraving, was probably invented north of the Alps, and it is in Germany, France and England, and above all the Netherlands, that the greatest triumphs of the process have been achieved. It will be most convenient in a brief summary of its history to deal with its progress in the Teutonic countries from its beginning to the end of the 17th century, and then to return to Italy, France and Spain. As a means of decorating metal, particularly armour, etching was practised at least as early as the middle of the 15th century. It seems probable that, as the earliest engraving was the work of goldsmiths, so the earliest etching is to be credited to the armourers. The idea of printing from such a plate they no doubt borrowed from the goldsmiths. The first etching, to which an approximate date can be given, is a portrait of Kunz van der Rosen by Daniel Hopfer (working 1493–1536), which a rather complicated line of reasoning assigns to the year 1504 or earlier. Daniel Hopfer was one of a family of armourers working in Augsburg, but was an artist of much originality. Hans Burgkmair the elder (1473–1531), the dominating personality of the Augsburg school, and on whom the Hopfers largely depended, executed a single etching, no doubt learning the process from the lesser artists. The earliest etching which actually bears a date is one by the Swiss goldsmith, soldier and draughtsman, Urs Graf (d. 1529), of the year 1513, most probably done at Basle. Albrecht Dürer (1471–1528), with the eagerness for experiment which characterized him, tried etching, but apparently found it an unsympathetic medium and after a few experiments gave it up in favour of engraving. His half dozen etchings dated between 1515 and 1519, impressed though they are with that great artist's personality, are among the least satisfactory of his reproductive work. Iron, the metal used in all these first attempts, did not allow of much delicacy, and the result, compared with line engraving on copper, for which it was regarded as merely a less laborious substitute, unsatisfactory. However, it was a new process which everyone must try out for himself. In Holland Lucas van Leyden (1494–1533), who probably learnt the process from Dürer during the German's visit to the Netherlands in 1520–21, etched a few plates. These are technically superior to Dürer's, and of importance as probably the first examples of the use of copper for etching, which made it possible for line engraving to be used in combination with it. The fine portrait of Maximilian which Lucas van Leyden made in 1521 is an example of this combined use of etching and engraving, the whole of the emperor's face being finished with the burin. Dirick Vellert at Antwerp (working 1517–44), an artist of delicate accomplishment, uses a technique much resembling Lucas's, though the majority of his works are engraved. Nicolas Hogenberg of Munich (working 1523–37), whose artistic career was passed at Malines in the service of Margaret of Austria, was one of the first northern artists to use etching with rapidity and freedom, and his frieze of the entry of Charles V. into Bologna in 1530, in a number of plates, is important from its size as well as from its subject. Frans Crabbe (the Master of the Crayfish; d. 1553), who was associated with Hogenberg, also followed his example in etching, but his work is unequal in quality.

Dürer's followers in Nuremberg, Hans Sebald Beham (1500–50) and Georg Pencz (1500–50) etched only a few plates, for the most part in the years immediately following Dürer's experiments. Albrecht Altdorfer (about 1480–1538) of Ratisbon, also no doubt impelled by Dürer's example, tried his hand at etching as early as 1519, and later used it for the first pure landscapes produced. Augustin Hirschvogel (1503–53?) and Hans Sebald Lautensack (working 1524–63) in Vienna followed Altdorfer's example in landscape, but without quite the freshness and charm of its originator. The only succeeding etcher of importance in Germany is Jost Amman (1539–91), who worked at Nuremberg.

In the Netherlands, line engraving usurped the field in the latter half of the 16th century and comparatively little etching was done. Jan Cornelisz Vermeyen (1500–59), the court painter of the Emperor Charles V., had etched a number of plates. He is probably the earliest example in the Netherlands of the painter, with no training as an engraver, turning his hand to etching. His plates, some of them of large size, are still executed in rather a formal style but are extraordinarily fresh and effective. Marcus Gheeraerts the Elder (*c.* 1521–1604), of Bruges, was the author of a charming series of small plates illustrating Aesop (1567), which are etched with a delicacy and sensitiveness hardly equalled by Adrian van Ostade or Hollar. Gheeraerts spent the latter part of his life in England, where he issued further etchings, the first to be published in that country. Hieronymus Cock (1510?–70), the publisher, did some admirable landscapes of the conventional type, and the great Pieter Brueghel (1525?–69) and Frans Floris (*c.* 1517–70), the fashionable painter of the time in Antwerp, each etched one plate, while Hans Bol, the landscape painter and draughtsman of Malines (1534–1593), within rather narrow limits, was an etcher of considerable charm. Paul Bril of Antwerp (1554–1626), who passed practically the whole of his life in Italy, is chiefly interesting as a link between the conventional Italian landscapes evolved in the Venetian school and the native style of the Netherlands. Hercules Seghers (*c.* 1590–1645), an artist of real originality, is dependent on Bril's theatrical conventions, while still in contact with Rembrandt. Seghers's curious experiments in printing and colouring by hand, though they cannot be actually classed as colour prints, as he never attempted to print with more than one colour at a time, are interesting and unique. Esaias van de Velde (*c.* 1590–1630) and his brother Jan (*c.* 1596–1641) are the earliest of the Dutch etchers who looked to Holland for the subjects of their landscapes. Simple, almost meagre in technique as their etchings are, they render with a naïve charm and directness the views in their native land. Willem Buytewech (*c.* 1585–1625), from whose drawings the Van de Veldes worked, is well known as a painter of individuality, which appears in his few etchings.

The enumeration of the names of these few etchers who worked in the Netherlands at the end of the 16th and beginning of the 17th century, leads up to, but does not explain the importance,

which, with surprising suddenness, the medium attained in the hands of Rembrandt Van Rijn (1606–69), and Anthony Van Dyck (1599–1641). The latter's achievement, remarkable as it is, is limited in scope and quantity, but as it precedes Rembrandt's in point of time will be dealt with first. The famous "Iconography" was planned by Van Dyck as a series of engraved portraits of contemporaries eminent in the arts. Etching was to play only a subsidiary and preliminary part in it, and, in fact, it was only for 18 of the 100 plates issued that Van Dyck himself executed preliminary etchings. The rest were engraved in line by the professional engravers trained in the school of Rubens. These 18 etchings, too, were subsequently finished by these same engravers, and it is only in the very rare impressions taken from these plates, before the additions were made, that Van Dyck can be appreciated as an etcher. His methods are quite independent of previous practice and of the conventions of line engraving. No doubt, the fact that he regarded the etching as merely preparatory, was partly responsible for their freedom from preconception. His natural instinct for form, aided to a certain extent by the example of Barocci and Italian etchers, led him straight to the secret of etching which we have since come to recognize is the essential one. His methods seem so obvious, that it is difficult as well as superfluous to try to describe them. Economy of line and contrast between this and the whiteness of the paper is the main secret. The heads stand out realized with quite extraordinary force and precision. There is no use of dry-point or of tone on the surface of the plate: the effect is gained by clean draughtsmanship.

Van Dyck's example as an etcher had comparatively little immediate effect; it is in modern times that his influence is most apparent. The great influence which he excited during his lifetime and for the rest of the 17th century was on portrait *engraving*, through the "Iconography" in its completed, engraved state.

Rembrandt's importance as an etcher is greater than Van Dyck's in proportion to the superiority and greater versatility of his genius. The number of his etchings, varying indeed with the trend of criticism from the 140 accepted by Prof. H. W. Singer to the 300 allowed by Prof. A. M. Hind, is at all events considerable, and comprises every variety of subject, scenes from the Old and New Testament, *genre*, portrait, still life, landscape. In his treatment of each subject in turn, his method is as fresh and untrammelled as was Van Dyck's in relation to portrait. But unlike Van Dyck's, Rembrandt's approach was gradual, and final and complete as each successive achievement appears to us, to him nothing was satisfying or final. The earliest dated etching, the small portrait head of his mother of 1628, is a masterly achievement, reflecting with great exactness the style of portraiture of his early Leyden period. Between this date and about 1632, his style undergoes no material change, though his etchings vary enormously in quality and elaboration. About 1636 the influence of Rubens, apparent in his painting, is correspondingly seen in his etching in a different and lighter chiaroscuro, with a tendency to sharper contrasts in light and shadow. The so-called "100 guilder print" of 1649 (Christ blessing little children) marks the apogée of his next period, in which dry-point plays an important part, and where the whole plate is covered with a network of fine lines, giving almost the appearance of mezzotint. To 1653 belong two of his largest and perhaps his most wonderful plates the "Ecce Homo" and the "Three Crosses," in the latter of which his feeling for the dramatic moment, his tremendous power of expressing emotion in terms of chiaroscuro, are triumphantly exhibited. The technique has become slightly less elaborate; heavy individual lines are more apparent, there is less use of cross hatching and a tendency to model in vertical parallels and a masterly use of the effects of tone left on the surface and of dry-point. In the etchings which follow up to the last-dated one of 1661, there is a further tendency towards the still broader and more drastic treatment visible in his latest paintings, and a more complete reliance on heavily etched line without dry-point. The landscape etchings, most of which belong to the years about 1640 and 1650, stand somewhat apart in the comparative simplicity of their aim as studies from nature, with the exception of the most famous, the "Three Trees" of 1643, which is as dramatic as any of his subject etchings. The portraits are, for the most part, in the more careful and elaborate technique of his earlier period, and perhaps insisted on by his sitters. The greatest are among the numerous portraits he etched from the mirror in every variety of costume and character.

Rembrandt's contemporaries in Holland, except for his immediate associates and followers Jan Livens (1607–74), Ferdinand Bol (1618–80), Jacob (*c.* 1616–1708) and Philips Koninck (1619–88) and J. G. van Vliet, remain comparatively uninfluenced. Anthonis Waterloo (1609?–1677?), who enjoyed in the 18th century an enormous and exaggerated vogue, has indeed some claims to importance as a landscape etcher, and Alart van Everdingen (1621–75), in his small plates, mostly of Norwegian scenes, shows a delicate and observant talent. Jacob Ruysdael (*c.* 1628–82) may claim a place next to, though indeed far below, Rembrandt's as a landscape etcher. His delicate and exquisitely finished etchings are in the nature of detail studies of particular woodland scenes, diversified by still water reflecting the trees. Of the Dutch painters who looked for their theme to Italy, Nicholas Berchem (1620–83) and Karel du Jardin (1622–78) are the best known. Their landscapes included as important parts of the composition human figures and animals, and they serve as a link connecting the landscape with the animal and *genre* painters. Of the animal painters Paul Potter (1625–54) is the most famous; of the *genre* painters Adrian van Ostade (1610–85). Ostade uses etching with a painter's eye, and knows equally well how to render with extraordinary subtlety the subdued light of the squalid interior, and the glow of sunlight on a scene of rustic festivity.

The only etcher of note to work in England during the 17th century is Wenceslaus Hollar (1607–77), who was born at Prague but spent the greater part of his life in the British Isles. Of the very large number of etchings which he executed the majority was intended to serve merely utilitarian and topographical purposes, but in spite of this nearly everything that he did shows at least a touch of real artistic feeling.

Though etching, as we have seen, was probably invented north of the Alps, it is in Italy that its potentialities as an independent graphic medium were first realized. Francesco Mazzuoli (Parmegiano) (*c.* 1503–40) in his few plates uses the etching needle not as a substitute for the burin, but with the freedom of the pen. His etchings are obvious reproductions of his masterly but rather facile drawings, which enjoyed a very great contemporary popularity, and he most probably employed etching as a method of satisfying the demand for his drawings. Following his example, most of the great Italian painters thought it incumbent on them to make at least a few etchings. Of Parmegiano's immediate following the Venetian painter, Andrea Meldolla (Schiavone) (d. 1582), is the only etcher of importance, and his work in this direction is almost entirely derivative from that of his prototype. Battista Franco (1498?–1561), the Venetian follower of Michelangelo, did a certain amount of etching, but in a lighter and more formal style, and the work of the other Venetians like Battista and Marco' Angelo del Moro, G. B. and Giulio Fontana and Paolo Farinati, show rather a reaction against the freedom of Parmegiano's style, to which, however, Jacopo Palma the Younger (1544–1628) returns with some measure of success. Federico Baroccio of Urbino (1528–1612), in his two or three etchings, works out quite a new and striking method of his own, detailed and careful, but at the same time quite different from the conventional engraver's style, and a masterly rendering of the peculiar effects of chiaroscuro at which he aimed in his paintings. Annibale Carracci (1560–1609), the most brilliant exponent of the so-called eclectic school of Bologna, in his few etchings is less original, but they still have the stamp of a real artistic personality.

In etching, as in painting, the artists of Italy are roughly divided into two schools during the 17th century: the one following the orthodox teaching of the Bolognese Carracci, the other deriving from Michaelangelo da Caravaggio. The division is no longer a territorial one and the eclectics worked side by side with the "tenebristi" or follower of Caravaggio. This close con-

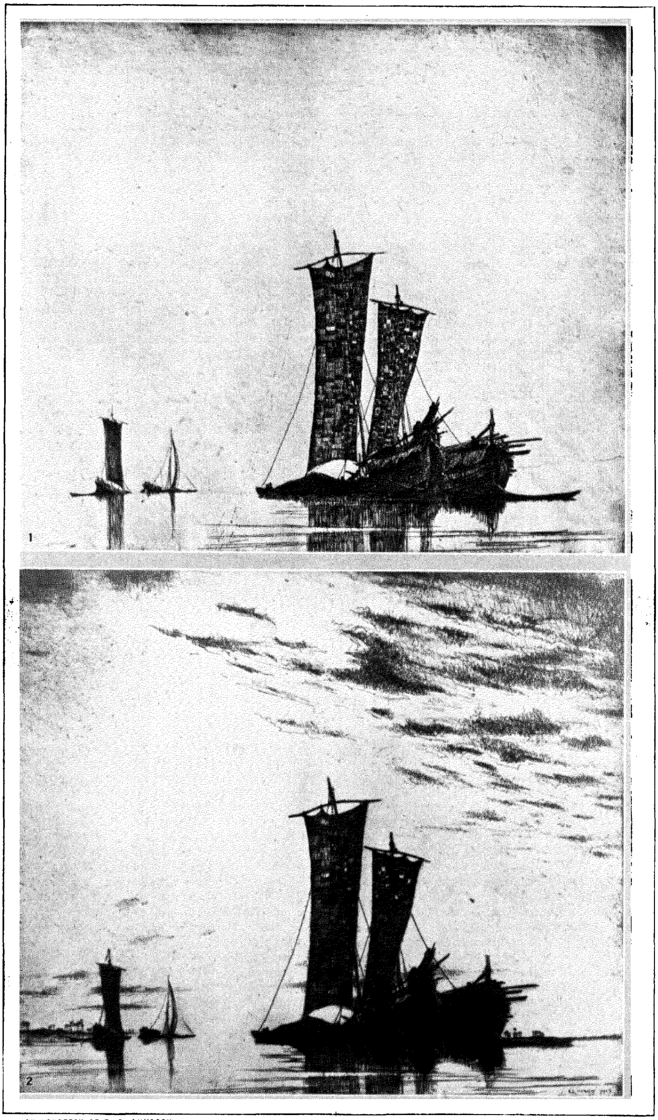
STAGES IN THE TECHNIQUE OF ETCHING

1. Alcantara Bridge, Toledo. The first trial state of an etching by E. S. Lumsden, showing alterations on the copper
2. Second state. The distance and water have been scraped out and re-drawn
3. Third state. The lines of the water have been removed once more, and replaced by vertical strokes
4. Final (published) state. The lines of the water have been re-drawn a third time, once more horizontally. The bridge remains untouched throughout, the difference in strength being due to printing only



BY COURTESY OF E. S. LUMSDEN

THE TECHNIQUE OF ETCHING

1. First trial-proof of the *first published state* of an etching by E. S. Lumsden. Nitric acid has been used throughout
2. Seventh trial-proof of the *second published state* of this etching. Additional work was done on the sky and the boats were re-bitten

tact led by degrees to a mutual influence by one school on the other and the original line of demarcation becomes gradually obscured. Guido Reni (1575–1642), an actual pupil in the Carracci school at Bologna, is the most eminent of the eclectic etchers, and his well balanced, delicately sentimental style became the classic type for most of the etchers in France and Italy during the century. Simone Cantarini and Giovanni Antonio and Elisabetta Sirani are agreeable echoes of Guido. G. F. Barbieri (Guercino) (1591–1666) in his few etchings is more original and shows some Caravaggiesque influence as does Giuseppe Caletti (*c.* 1600–60). G. F. Grimaldi (1606–80?) the chief landscape etcher of the school, is conventional and dull. Carlo Maratta (1625–1713) carries on the Carracci style into the 18th century. The greatest etcher working in Italy in the 17th century is undoubtedly the Spaniard José de Ribera (1588–1652). His style, in so far as it is not to be classed as Spanish, is definitely Caravaggiesque, but his technique as an etcher is partly derived from the Bolognese. The sensitiveness of his outline, which plays an important part in his work, and the sureness with which he knows how to render the changes from brilliant light to darkest shadow, are extraordinary. Ribera's pupil, the Neapolitan Salvator Rosa (1615–1673), the painter of romantic bandit-infested landscapes, in his etchings, the less pretentious ones particularly, shows some of the charm which we associate with his fantastic world. In Genoa, Benedetto Castiglione (1616–70), whose talent has something in common with Salvator's, is attractive from the grace which characterizes his etchings and interesting from the fact that he was influenced by Rembrandt's work. In Venice, Giulio Carpioni (1611–74) etches with vividness and grace romantic scenes in a technique derived from the Carracci. Pietro Testa (1611–50), who worked in Rome, is an unequal but not uninteresting artist, with a curiously Venetian feeling for light which anticipates Tiepolo.

Little etching was done in France in the 16th century. The frescoes decorating the palace at Fontainebleau executed by Rosso Fiorentino, Primaticcio and their followers, were reproduced in etching by Antonio Fantuzzi, Leonard Thiry and other artists engaged in the work, but these are crude and hasty works. Jean Cousin (d. 1590) is credited with two or three etchings of more merit, and the architect and designer, Jacques Androuet Ducerceau (*c.* 1510–80), used etching for his delightful architectural compositions with a truly French grace. But with the 17th century and the names of Jacques Callot (1592–1635) and Claude Lorrain (1600–82), France attains a position of real importance in the history of etching. Callot, unlike most of his contemporaries and successors who depended almost entirely for their inspiration on Italian classicism, is essentially and originally French. Technically, his innovations consist in his handling of the individual line, by the thinning and thickening of which exclusively his effects are obtained, but he is also the inventor of a new world of minute fantastic figures, a sort of French stage fairyland. Besides their extraordinary elegance, such series as the *grandes* and the *petites misères de la guerre,* have a point and an emphasis in their narrative which is surprising on so minute a scale. The technique of subsequent etching could not and did not remain uninfluenced by Callot's practice, but his only close follower is an Italian, Stefano della Bella (1610–64). The French academicians of the *grand siècle,* Le Sueur, Le Brun and the rest with their ready-made classical formulae had no chance of success in a medium as personal as etching should be, and it remained for Claude Lorrain with his direct reactions to the landscape which he saw around him to produce the only great etchings of the period besides those of Callot. Though his conception of landscape painting was bound by certain theatrical conventions, in his drawings and etchings he approaches his subject directly and at the same time with the true landscape painter's instinct for selection. He is not a good etcher technically; there is something fumbling and amateurish in his work, but in spite of these disadvantages, he somehow succeeds in producing landscape etchings of an extraordinarily moving quality.

The 18th century did not find in etching its most characteristic means of expression. In France, whose artistic preponderance in Europe during the period, was undisputed, line engraving was more extensively and more successfully practised. Etching was to a large extent employed, it is true, but mostly as a preliminary to or in conjunction with engraving, and such mixed productions may more legitimately be classed as engravings (*q.v.*). Antoine Watteau (1684–1721), François Boucher (1703–70), Honoré Fragonard (1732–1806) and the brothers Augustin (1736–1807) and Gabriel de St. Aubin (1724–80), all practised etching to a limited extent. Jean Duplessi-Bertaux (1747–1813) etched historical scenes largely of republican and Napoleonic times with a spirit and delicacy quite in the tradition of Callot.

It is, however, in Italy and Spain that the great etchers of the century flourished. Giovanni Battista Tiepolo of Venice (1696–1770), whose brilliant decorative painting is the culmination of rococo art, showed as an etcher equal brilliance. His technique, recalling that of José Ribera and G. B. Castiglione, is yet entirely original in its almost complete avoidance of heavy defining shadow and his method of rendering the broad, grey shadows by systems of herring bone and irregularly arranged short lines. His scenes, laid in a brilliant and all-enveloping sunlight, comprise some of the stock 18th century sylvan and Arcadian *genre,* as well as more imaginative subjects, but treated alike with a peculiar point and irony. Antonio Canale (Canaletto) (1697–1768), Tiepolo's contemporary in Venice, distinguished as the most brilliant portrayer of his native city, was an etcher of almost equal distinction. His 31 etchings of Venice and the neighbourhood reproduce faithfully the quality of his painting. It is, indeed, remarkable in him and in Tiepolo how their etching is directly dependent on their painting. They seem each independently to have discovered that method of etching extraordinarily complicated and original, which would most exactly correspond to the essential quality of their painting. In each case the result is not, as might have been anticipated, a lifeless reproductive technique, but a brilliant addition to the repertoire of etching. Giovanni Battista Piranesi (1720–78), the third great Italian etcher of the century, though also a Venetian by birth, worked nearly all his life in Rome. The bulk of his very extensive etched work is archaeological, but his feeling for architectural composition and for the quality of the etched line entitle this work to be regarded from the artistic point of view.

Francisco Goya y Lucientes (1746–1828) inevitably finds a place at the beginning of any account of modern art, and indeed his work looks forward into the 19th rather than backward into the 18th century, so extraordinarily fresh and original it is and so free from any of the typically rococo elements which mark 18th century art. Yet technically, Goya derives from Tiepolo (he visited Italy during his youth) and his earliest work in etching, though it reproduces paintings by Velázquez, is very much in Tiepolo's style. But his original compositions, the series of the *Caprichos,* the *Proverbios,* the *Desastres de la Guerra* and last of all the *Tauromaquia,* show the evolution of an original technique with the use of aquatint for the backgrounds. The mysterious satirical works, the *Caprichos* and *Proverbios,* although the exact target at which their shafts are aimed is uncertain, are overwhelming in the bitterness and intensity of their satire and the horror of the imagination which they show.

With the notable exception of Goya's work there is comparatively little of interest to record in the field of etching during the first half of the 19th century. It is one of those periods of stagnation which occur before a revival. In England, work of distinction, based on that of Rembrandt's contemporaries such as Ruysdael, was done by John Crome (1768–1821) of Norwich, as well as by John Sell Cotman (1782–1842), most of the latter in the process, invented at the end of the 18th century, called soft-ground etching. The names of Thomas Girtin (1775–1802) and J. M. W. Turner (1775–1851), can hardly be omitted in view of their pre-eminence as landscape painters, but their work in etching, masterly as it is, was in neither case intended to be final. Girtin's etchings were preparatory to aquatints and Turner's to mezzotints. Andrew Geddes of Edinburgh (1783–1844) is the author of a number of plates of real distinction, marked by a considerable and intelligent use of dry-point, and Samuel Palmer

(1805–81) is a landscape etcher of individuality.

The painters of the "Barbizon" school of landscape in France, Théodore Rousseau (1812–1867), Charles Jacque (1813–1894), C. F. Daubigny (1817–78), J. F. Millet (1814–75) and Camille Corot (1796–1875), all etched. The most prolific and important for his influence on the etchers of the next generation was Jacque, whose style shows the influence of Ostade and the Dutch etchers of the 17th century, while C. F. Daubigny, as an etcher, shows great power and originality. Millet in his plates, executed in a style which resembles that of Ostade's etchings magnified to about four times their original size, portrays those subjects of peasants at work familiar in his paintings, with the same instinctive understanding. Corot used the etching needle only occasionally, but in a manner which, for all its seeming scratchy incompetence, vividly reproduces the atmospheric effects of his paintings. The greatest figure in French etching of the century, that of Charles Meryon (1821–68), stands rather curiously aloof from that of his contemporaries. Precluded by colour blindness from the practise of painting, he is that rather rare phenomenon—an etcher who is not a painter. Influenced by a study of the work of the admirable, but comparatively little known Dutch 17th century topographical and marine etcher, Reynier Zeeman, and obviously, to a certain extent, by Piranesi rather than by contemporaries, Meryon evolved for himself a system of line which, in its clarity and incisiveness, is unrivalled for the rendering of architectural subjects. His reputation, resting, as it does, on a small number of plates of the streets and churches of Paris, might, on the face of it, seem exaggerated, but the extraordinary perfection and inevitability of design which these show seem to create out of a restricted subject matter a formula of universal application.

The revival of etching in England in the 19th century was due, in large measure, to the influence of three men of whom undoubtedly the greatest was James McNeill Whistler (1834–1903). American by birth, but thoroughly cosmopolitan, a large part of his life was passed in England and it was here that his influence was perhaps most pronounced. His conception of etching, as of art in general, even more than his practise, has had the profoundest effect. Rembrandt was undoubtedly the chief influence on his etched work. His idea of an etching as an exact and inevitable composition from which no single one of the innumerable lines which go to make it up could be removed or displaced by a hairbreadth, is almost justified by the perfection of some of his exquisite plates. Sir Francis Seymour Haden (1818–1910), Whistler's brother-in-law, though an amateur, exercised a direct influence on English etching even greater than Whistler's, who had little immediate following. Haden was by no means an echo of Whistler: though inspired by him in the first instance, his was too independent a character to allow of anything in the way of imitation. He also went back to Rembrandt for inspiration and etched with an incisive strength and clarity which are admirable, though his work can hardly compare with the greatest. The third important influence on English etching was that of Alphonse Legros (1837–1911), a Frenchman and first Slade professor of art in London, where most of his life was spent. His was not a talent of extreme originality, but he had a great feeling for, and understanding of, etching and an extraordinary power of assimilating the methods and thoughts of the great masters.

Whistler had in Théodore Roussel (1847–1926) another Frenchman settled in England, a follower as fastidious as himself who later evolved an original method of colour etching; and in Walter Sickert (b. 1860), an artist of real originality who has since developed along his own lines and founded an important school. In the tradition of Seymour Haden may be counted Sir D. Y. Cameron (b. 1865), whose landscape etchings and dry-points are marked by faultless taste and distinction, and Muirhead Bone (b. 1876), who has specially developed the architectural theme. The most distinguished pupil of Alphonse Legros was William Strang, whose portrait etching in particular is admirable, but who perhaps fails by a lack of concentration in his powers to convince as a great etcher. The etched work of Augustus John (b. 1879) is the characteristic occasional work of an important painter, in the tradition of the great masters, while that of Franck Brangwyn (b. 1867) is distinguished by its impressive size and feeling for composition in landscape and architecture. Sir Frank Short (b. 1857), for many years director of the school of engraving at South Kensington, exercised, after Haden and Legros, the greatest influence on etching, and was himself an etcher of great technical ability, though perhaps better known as the reviver of the process of mezzotint.

The succeeding generation has been extraordinarily prolific in etchers of real distinction, and the first quarter of the 20th century may well come to be regarded as one of the important epochs in the history of etching. It is a matter of difficulty to class and arrange contemporary achievements, and it will suffice to name a few of the more prominent. As an etcher of landscape as well as of subject, largely Eastern, James McBey (b. 1883) has certainly attained an important position by the originality and strength of his work. Henry Rushbury (b. 1889), in a style something akin to Muirhead Bone's, is doing extremely fine work in landscape, while Sir George Clausen (b. 1852), E. S. Lumsden (b. 1883) and many others have a merited reputation in the same *genre*. F. L. Griggs (b. 1876) has revived the imaginary architectural composition originated by Piranesi, and made of it a delicate and original means of expression. In portraiture, Francis Dodd (b. 1874), Gerald Brockhurst (b. 1890) and Malcolm Osborne (b. 1880) have done admirable work.

In Holland, as might well be expected, much work of importance was done in the second half of the 19th century. J. B. Jongkind (1819–91), Josef Israels (1824–1911) and Mathijs Maris (1839–1917), though the work of the latter is the occasional essay of a painter, are artists of the first rank, while C. Storm van's Gravesande (b. 1841) and Marius Bauer (b. 1867), of whom the latter is still in the plenitude of his power, have contributed something considerable to etching. Scandinavia has produced one etcher of astonishing virtuosity in the person of Anders Zorn (1860–1920), and in Germany and Austria, while no artist of the very first rank has, so far as one can judge, appeared, much etching of real distinction has been and is still being done. Since Whistler the interest in etching in America has been very intense and a great deal of work has been done, largely, it is true, by artists working abroad, of whom Joseph Pennell, D. S. Maclaughlan (a Canadian by birth), Frank W. Benson, Herman J. Webster and Arthur W. Heintzelman are perhaps the most notable. (*See* also LINE ENGRAVING; DRY-POINT; WOODCUT; LITHOGRAPHY.)

P.)

TECHNIQUE

Materials.—The essentials for producing an etching are: (1) A metal plate; (2) a mordant resist or "ground"; (3) a point which will cut through the ground; (4) a mordant; (5) ink, paper and press. For fine work artists generally prefer copper, for coarser, simpler designs zinc is equally capable of yielding the best results. But from the closer-textured copper a greater range in light and shade is possible.

Before applying the "ground" the plate's surface must be cleaned thoroughly, to allow as perfect contact as possible. This may be done by means of any solvent—turpentine, benzine, petrol or ammonia—with whitening and a soft rag. Tarnish may be removed with vinegar (or acetic acid) and common salt.

The Ground.—Rembrandt's is said to have been: (*a*) Virgin wax, 1 oz.; mastic, ½ oz.; asphaltum or amber, ½ oz.; or (*b*) wax, 2 oz.; Burgundy pitch, ½ oz.; common pitch, 2 oz.; asphaltum, 2 ounces. A similar recipe is in use to-day. The ingredients are melted together carefully—first the asphaltum, then the wax, and last the pitch or mastic. The mixture should be allowed to boil up two or three times and then poured into warm water to set, being formed into suitable balls while in the water.

A transparent ground may be manufactured with five parts of wax and three parts of gum-mastic by weight. The ground

is applied by melting on the heated plate and spreading as finely and evenly as possible by means of a so-called "dabber" or leather-covered roller. To make the dabber, a circular card about 2 in. in diameter is cut, a wad of cotton-wool placed upon it, and the whole covered with fine kid or silk. Before the ground cools the usual though by no means universal practice is to smoke it by passing the inverted plate backwards and forwards—taking care never to rest at one spot—over wax tapers or an oil lamp. This dark surface shows the line and strengthens the ground as a resist.

In place of smoking Rembrandt is said to have used a white lead powder. This has the advantage of causing the line-work to appear dark on a light surface, like drawing with a grey pencil on paper. Quite recently a Scottish etcher, Henry Daniel, has discovered that, for this purpose, oxi-chloride of bismuth has admirable qualities. It is spread over the still slightly-warm ground with a very soft, full brush. Not being really incorporated with the ground it is attacked and removed by the acid when biting begins, but this is no great disadvantage. Many etchers prefer a liquid made by dissolving ordinary ground in ether or chloroform. This is poured very quickly over the plate (in a tray) and the residue returned to its bottle.

Points.—Every etcher has a favourite point. A most satisfactory and easily made one is a long gramophone needle pushed butt-foremost into a pen-holder and secured with sealing-wax. This is an ideal, not too sharp yet fine tool. Another, which serves equally for additional dry-point work, is the engineer's pricker, the points of which can be changed and reversed while in the pocket. The object of the needle is to remove the *ground* without scratching too much into the *metal*. A very sharp point destroys freedom, and causes irregularity in the attack of the mordant.

Biting.—When the drawing has been made upon the prepared wax surface with as steady and equal pressure as possible, comes the *biting* or fixing of the design. If the plate is to be entirely submerged the back also must be first coated with a resist. For such a purpose a liquid varnish is necessary, as to re-heat the plate would destroy the lines drawn. The best ingredients are methylated spirit and shellac (in proportion two to one) to which some black pigment has been added to cause less fluidity and allow the varnish to be visible when dry.

Three mordants are commonly employed at the present day. The first, and most used by artists, is nitric or nitrous acid mixed with an equal quantity of water. The second, the so-called "Dutch mordant" is prepared by dissolving ½ oz. potassium chlorate in 5 oz. of hot water, and adding 1 oz. of hydrochloric acid. The third is iron perchloride, most used by process-etchers. Artists probably prefer nitric because it is much the most rapid in action, and because the constant and obvious ebullition makes easy the detection of any over-looked line or dust-hole in the ground. The other mordants attack more gently without bubbles, consequently "foul-biting," as it is called, may easily go on unnoticed until too late. On the other hand, iron perchloride, while reasonably fast, bites more deeply in proportion to the width of line, as the edges are not broken away and the ground undermined as happens with strong nitric. The iron also darkens copper, permitting the lines to be more easily watched if used with an unsmoked ground. Its only drawback is the formation of sediment, which retards the action at the bottom of the lines, but can be dispersed by keeping the bath in motion. If rocking is not sufficient, the plate must be bitten inverted—resting upon slips of wood or other material not affected by the mordant—after which the deposit can be distinctly seen at the bottom of the dish. Full (saturated solution) strength is too thick for fine etching, and half that or a little more is far quicker than the cold "Dutch" bath. In many ways iron perchloride is the most reliable of the three mordants.

Before beginning the biting it is well to place the plate in a bath of commercial acetic acid for a few minutes, in order to remove impurities which may otherwise clog the lines—perspiration from the hand while drawing, for instance. This is particularly needful when one portion of the drawing has been made considerably prior to another. It allows all parts to be attacked simultaneously, which in the case of a delicate distance, for instance, needing but a very short biting, is of the utmost importance.

Various Methods.—In working the more orthodox plan is to complete the drawing entirely before beginning to use the acid. Then the plate, placed bodily in the bath, is left sufficiently long for the most delicate lines to be etched. The determining of the exact moment for removal is largely a matter of experience. The plate is then washed with water, carefully dried by means of blotting-paper, and those lines which are deemed of sufficient depth "stopped out" with a fine brush and the shellac varnish. Allowing this to dry, the process is then repeated until those lines which are required to be deepest of all are bitten when the plate is, for the time at least, finished. In the earliest days of etching no stopping out was reverted to, Dürer and Hopfer biting their lines to one depth only; and, generally speaking, the fewer stoppings the simpler and better the result.

Then there is the method employed by Haden. It is the reverse of the preceding. With the grounded plate placed in the bath, the artist begins by drawing those passages which he desires to be the strongest of all. As the lines are drawn the acid attacks them and the etcher passes on to the next darkest parts, ending by drawing the faintest lines immediately before removing the plate from the bath. This obviously requires great speed and certain judgment, allowing of no mistakes or hesitation. It is the resulting spontaneity which so charms in Haden's work.

Lastly, there is the compromise between the above processes resorted to by Whistler in his later manner. The drawing is more or less completed—in Whistler's case out of doors—then a little acid is poured upon it and (controlled by a feather) moved about here and there, being permitted to stand longer on some lines, less long on others, until the whole is bitten without recourse to stopping out. At the same time new lines are added where required to give strength or closer texture, light lines often crossing stronger ones (as also in Haden's method) and yielding less formality in the result than is easily obtainable by the older way of working.

But the etcher is by no means compelled to do the whole of the work upon a single ground. It is often expedient to do part only, remove the wax by means of turpentine or other solvent, pull a proof as a guide, re-ground the plate and continue. In re-grounding (which cannot safely be done with the roller) care must be taken to fill in the already bitten lines, as their edges are very liable to be attacked in renewed biting. Insufficiently bitten work can also be rebitten by carefully laying a ground on the surface only (here the roller is perhaps safer than the dabber) while leaving the lines open. It is a hazardous undertaking, except where already deep lines are concerned, and generally results in loss of definition.

Proving.—When biting has been accomplished by one method or another and ground and backing removed, the plate is ready for "proving." The result will be the *first state* of the plate. *Any* additional work constitutes a new state, without relation to the number of proofs printed. There may be one only or 500 of each state; but the removal of a single line or adding of, say, a date creates technically a further state. Even where the artist, realizing that his alterations were a mistake, returns as nearly as possible to his original, the last will still be the third state, if proofs of the two previous ones are preserved. For instance, the eighth state of Whistler's "Bridge" is only distinguishable from the first by careful examination of both, though intermediate proofs are easily recognized. These working states are known as trial-proofs, as when an addition of more than one state is published the tentative trials are ignored—only those issued receiving the titles of first, second or third *published states*, *e.g.*, Haden's "Agamemnon." Few etchings are left untouched after the first ground is removed, and it is as often necessary to cut out lines as to add them. For this a "scraper" is required. It is a tool difficult to handle and to sharpen. To remove the marks left by the scraper, snakestone is used with water, and to regain the polished surface charcoal and water and finally oil or plate-polish. Another useful etching tool is the polished steel "burnisher." With this light scratches may be rubbed out or over-heavy lines reduced. With these implements and soft rag almost anything is possible in the way of alteration. The pulling of the proof itself is one of the most fascinating of the processes which together go to the making

of an etching. And yet quite a number of etchers delegate this—the real birth of the final work—to a professional printer!

PRINTING AND PAPER

Printing.—The expense of a really good roller press is perhaps partly responsible, but a good proofing press is an essential. Small machines which have little power are worse than none at all, as their results are apt to discourage the beginner. The more delicate the line in the plate the more pressure—"pinch"—is necessary. The best modern presses are geared, and the large double-geared ones can be run with little physical exertion. The old machines were built with wooden rollers and travelling-bed, the modern entirely of iron and steel. The printing-ink is formed by grinding Frankfürt or French black powder (mixed usually with umber or burnt sienna to add warmth) with burnt linseed-oil. The burning of the oil thickens it and makes it more adhesive. Several strengths are used, which yield very different results. When mixed and well ground the ink should be sufficiently stiff not to fall quickly from the palette knife, and it is spread solidly over the surface of the heated plate by a roller or the older dabber.

The roller is made of gelatine, covered by some material to prevent adhesion when the warmth from the plate softens its composition. Stockinette is excellent for the purpose, but great care is needed to avoid any scratching edge at the seam. The roller's length should be about 3 in. and its diameter 2½ inches. The ink, after being well worked into the lines and spread evenly all over the plate, is wiped off gradually by means of pads of stiff book-muslin or Swiss-tarlatan. The hand presses firmly and equally—avoiding a scooping action—as if polishing the metal. A firm pressure forces the ink into the lines while removing it from the surface—all but a very fine film. A "clean-wiped" proof is finally polished by the base of the palm.

To soften and enrich the clean-wiped plate a piece of clinging muslin may be dragged lightly over the surface, pulling the ink a little out of the lines. This is called *retroussage,* "dragging" or "bringing up." It can also be done by going over the plate once more with the fully charged printing muslin, but this leaves a slightly granular effect upon the surface as well. Wiping is capable of great variation and the strength of oil plays an important part in the way in which the ink comes off the surface. An etching is never wiped so that no film of oil remains. A good printer will consider what colour, of ink and paper, will produce the best result; whether the plate shall be clean or only rag wiped, etc.

Paper.—Many etchers prefer old paper because the decay of its size renders it soft and pliable, and consequently more readily folded into the lines in passing between the rollers. Its colour is also more beautiful and often it is made of better material—that is, linen rags unspoilt by modern bleaching with dangerous chemicals, or adulterated with dressings.

The paper is well damped before use but should have no excess moisture on its face. This may refuse the surface film of oil on the plate and white granulations appear on the proof. Very thin oil is specially prone to do this. Before beginning to print, the edges of the plate should be examined and filed smooth, to prevent the paper being cut. When the inking and wiping has been accomplished, the warm plate is laid upon the travelling-bed of the press, a sheet of paper is taken from its damp pile, examined for hairs or dust, and placed face down upon the plate, one or two sheets of new soft blotting-paper laid over it and five or six thicknesses of printing blanket over all. The blanket is of two qualities—the two nearest the plate being fine "fronting" and the rest of coarser thicker material. When everything is in place the whole is pulled between the rollers, once only. Removing the blankets, the printing and blotting papers are peeled off the plate in one solid piece. When dried, the proof can be removed and flattened.

FURTHER METHODS

Soft-ground.—This method—the French *vernis mou*—is much less practised than it was in the early 19th century. The line somewhat resembles a chalk drawing. Its granulated texture renders it very suitable as a basis for aquatint, but its own qualities were fully exploited by that great master, Cotman. Everything depends upon the addition to the ordinary etching ground of tallow, usually an equal quantity, in hot weather less. This makes a very clinging compound, with which the plate is covered in the normal manner; but instead of being directly drawn upon, a sheet of grained paper is placed over the surface and the drawing executed upon this with a pencil, care being taken to avoid contact with the paper otherwise than with the point. When the design is complete the paper is peeled off, taking with it those portions of the ground corresponding to the lines drawn. The stronger the pressure the more ground will stick to the paper and the wider the line exposed ready to be bitten by the acid. The grain of the paper will show in the character of the bitten line. Except that stopping-out is hardly required, the biting is carried out exactly as described above. The line relies upon breadth rather than depth for variation. A smooth paper will hardly produce any result, but tissue is excellent. Tissue paper is also serviceable for re-working, as it is semi-transparent.

Aquatint.—Instead of with line aquatint deals with tone in broad masses. In most of his plates Goya, the greatest exponent of the medium, employed an etched line as guide and basis for the tonal work, but not in all. (*See* AQUATINT.)

A variant of aquatint is to form the porous ground by passing an ordinary wax ground through the press several times in contact with sand-paper; this is known as "sand-grain." Its fineness depends upon the quality of the paper and the number of passages through the rollers. Stopping-out and biting proceed exactly as before. Joseph Pennell produced some good plates in this manner.

Pen-method.—This has recently been revived in London. It was used by Gainsborough in conjunction with aquatint, and though hardly possible to employ for fine work, its quality blends better than that of the needle line with tone work. The drawing is made upon the bare plate—good results have been obtained on steel in recent times—with a pen or brush and ordinary ink or a soluble gum—gamboge and water is excellent. When dry (but not more than a day old, or it will harden), an etching ground is laid over it, not too thickly. When this is hard the plate is submerged in water for half an hour or so, whereupon the ground above the lines will come away as the ink dissolves. The lines can then be bitten in the usual manner.

ETESIAN WIND, a local Mediterranean summer wind blowing chiefly from the north but occasionally from the west for about six weeks annually. (Gr. ἔτος, year.)

ETEX, ANTOINE (1808–1888), French sculptor, painter and architect, was born in Paris on March 20, 1808. He first exhibited in the Salon of 1833, his work including a reproduction in marble of his "Death of Hyacinthus," and the plaster cast of his "Cain and his race cursed by God." Thiers, at that time minister of public works, now commissioned him to execute the two groups of "Peace" and "War," placed at each side of the Arc de Triomphe. Among the best known of his architectural productions are the tomb of Napoleon I. in the Invalides and a monument of the revolution of 1848. He died at Chaville (Seine-et-Oise) on June 14, 1888.

ETHER (in Physics).—Whether space is a mere geometrical abstraction, or whether it has definite physical properties which can be investigated, is a question which in one form or another has often been debated. As to the parts occupied by matter, that is by a substance which appeals to the senses, there has never been any serious doubt; almost the whole of science may be said to be an investigation of the properties of matter. But from time to time attention has been directed to the intervening portions of space from which sensible matter is absent; and this also has physical properties, of which the complete investigation has hardly begun.

These physical properties do not appeal directly to the senses, and are therefore comparatively obscure; but there is now no doubt of their existence, even among those who still prefer to use the term "space." But a space endowed with physical properties is more than a geometrical abstraction, and is most conveniently thought of as a substantial reality, to which therefore some other name is appropriate. The term used is unimportant, but long ago the term ether was invented; it was adopted by Isaac Newton, and is good enough for us. The term ether therefore connotes a genuine entity filling all space, without any break or cavity anywhere, the one omnipresent physical reality, of which there is a growing tendency to perceive that everything in the material universe consists; matter itself being in all probability one of its modifications.

Many attempts have been made to state the properties of such a substance in terms of material analogies, and all these attempts have shown signs of weakness and may be said to have failed. The properties of the ether are too fundamental to be stated in terms of something else.

There have been tendencies at different times to invent ethers or effluvia with special qualities to account for specific phenomena. These attempts were long ago discarded, and are now regarded as absurd. But that space has physical properties is a definite fact of experience, provided experience is extended to include inferences and deductions and is not limited to direct sensual perception. What we perceive directly are length, breadth and height, modified here and there by a resistance or obstruction which we call matter, and combined with the element of time or duration, as exhibited and measured by the motion of matter, with speeds that can be directly apprehended.

But in addition to all that mass of common experience, the free unobstructed space is modified by the neighbourhood of matter; so that there exists everywhere a gravitational potential varying inversely with the distance from its appropriate portion of matter; the result of which is that matter tends to move from places of higher to places of lower potential, as if some force were driving the masses of matter together. Civil engineering—the erection of structures and the movement of great masses of material—is constantly concerned with this fact; and on this basis the whole of the older astronomy has been worked out in the most intricate detail.

Testimony of Optics.—The atoms of matter are not quiescent, even when a mass appears stationary, but are in a state of rapid quivering motion; and these motions are not independent of each other, but are interrelated and connected by additional and special disturbances which they communicate to the space or medium in which they occur. And about these supplementary disturbances our sense organ, the eye, has given us a mass of indirect information. These disturbances, though generated by matter, are not conveyed or transmitted by matter. They travel at a rate depending on innate properties of space; or rather, as we feel bound to say, on the physical properties of the substantial reality which fills space; thereby telling us something definite about those properties, though in a form difficult of apprehension and one which is not fully expressible in terms of any of the familiar properties of matter.

Thus the different masses of matter, even though separated by great distances, are not isolated or independent of each other. They are connected gravitationally, and they are connected optically. The energies of the earth, of which we constantly make use, are derived from the sun, and have travelled across the intervening 92,000,000 miles of empty space at a perfectly known and definite rate, with which rate matter has nothing to do. There may be uncertainty as to what exactly it is that is travelling; but the fact that it is travelling energy is certain. All that matter does is to generate this radiant energy at one end and absorb it at the other. (*See* Radiation Rays; Physics.)

Concerning the processes of generation and absorption a good deal is now known. Moreover not only is the speed of travel of the transmitted disturbance known, but also the fact that it is a periodic disturbance, expressible mathematically in exact analogy with a wave equation. Wherefore the disturbance may be spoken of without further hypothesis as ether "waves," the generic name for which is "radiation," a small range of this radiation being visible light.

Radiation is generated by some cataclysm or collision or other violent and sudden disturbance in the atoms of matter. When radiation encounters matter (unless it be merely reflected or passed on) it can throw the multitude of atoms into the confused motion we call "heat," and produce other remarkable and chemical effects. Thus an ether is necessary for the purpose of transmitting what is called gravitational force between one piece of matter and another, and for the still more important and universal purpose of transmitting waves of radiation between one piece of matter and another, however distant they be.

Electric and Magnetic Properties.—In addition to those two functions, other properties have been discovered, notably the properties called electric and magnetic. Atoms of matter are electrically constituted, and accordingly tend to attract each other with a force which is the source of chemical affinity; with the result that molecules and other aggregates are formed, of which the structure is studied in the science of chemistry. Moreover the molecules themselves attract each other by a residual affinity, giving the familiar shape of crystals and other solids, the particles of which are held together in regular packing across ultra-microscopic intervals by what is called cohesion, for which likewise the ether must be held responsible. For, as Newton forcefully said in other words, it is absurd to imagine one piece of matter acting mechanically on another at a distance, whether that distance be large or small, without some intervening mechanism or connecting link. The continuous medium which fills space, therefore, is not only the vehicle of gravitation and light, but is also the instrument for cohesion and chemical affinity and for electric and magnetic attractions and repulsions. It must also be the vehicle for every kind of mechanical force, and for the elastic connection between particles of matter, which are never in real contact with each other.

The intimate structure of the ether may ultimately be expressible and partially understood in terms of the phenomena of electricity and magnetism: for electric and magnetic influences are transmitted perfectly through vacuum, that is, across space empty of matter. They represent primarily properties of the ether, though they are only made manifest to our senses by means of matter. It was in terms of electricity and magnetism that Clerk Maxwell was able to explain the phenomenon of light. A close study of electro-magnetism, that is, of the interaction between electric and magnetic disturbances, showed that they must combine into a wave equation, the waves being transmitted at a rate calculable from purely electric and magnetic considerations. This velocity turned out to be the velocity of light; and so in 1865 the true theory of light was born.

Not that it is anything like complete. We know too little of the electric and magnetic properties of the ether to be able to picture exactly what is happening. What we do know is that light is an electro-magnetic phenomenon, and that it is entirely dependent on the properties of the ether. The ether involves or possesses properties expressible by two fundamental constants; one of which regulates the force of attraction between two electrified bodies, and the other the force of attraction between two magnets. Neither constant by itself is as yet known. But the value of the constants multiplied together is known; it was discovered by Clerk Maxwell, and is the reciprocal of the square of the velocity of light. In other words, the combination of the

electric and magnetic properties of the ether enables it to transmit waves at a rate equal to the inverse geometric mean of its two constants.

So far we have been dealing with things which have been known for some time. But the subject is so fundamental and important that a recapitulation in other terms seemed advisable. It now remains to deal with the later progress which has been made in investigating the properties of this extraordinary non-material but physical substance. Perhaps "substance" is hardly the right term, for, though exceedingly substantial in one sense, it makes no appeal to the senses and is therefore unlike any substance we know.

In the 9th Edition of the *Encyclopædia Britannica* an attempt was made to estimate the elasticity and the density of the ether, on the strength of a certain hypothesis made by Lord Kelvin. In the 11th Edition (1.292) this estimate was repeated, and it was hinted that the hypothesis might be erroneous and the values obtained exceedingly wrong. Everything tends to confirm that conclusion. Strictly speaking the very terms elasticity and density, which are terms applicable to matter, may be inapplicable to the ether without re-definition; if used they must be understood in a formal sense. The properties of the ether are not likely to be expressible in terms of matter; but, as we have no better clue, we must proceed by analogy, and we may apologetically speak of the elasticity and density of the ether as representing things which, if it were matter, would be called by those names. What these terms really express we have not yet fathomed; but if, as is now regarded as very probable, atomic matter is a structure in ether, there is every reason for saying that the ether must in some sense be far denser than any known material substance. The only alternative contention—and it is an important one—is that the density which displays itself as inertia may be due to the organisation responsible for the very existence of matter, and that the unorganised general body of ether does not possess the attribute of inertia. The densest known matter, or matter of highest inertia, is found in some of the stars; the barely visible companion of Sirius having been found, on converging grounds of evidence, to be more than 1,000 times as dense as lead. Unless the above alternative contention turns out true, the density of ether must exceed even that startling amount; indeed there are sound arguments for regarding it as a million times denser. The fundamental substance is not likely to be filmy and unsubstantial.

Recent discoveries have represented the atom of matter as composed of minute electric charges, which fill hardly any of the space inside the atom, so that it is as porous as a solar system. (*See* ATOM.) The great bulk of an atom is occupied only by a few electrons; so that it is by no means impenetrable to particles, which if they fly through it at sufficient speed, may escape being entangled and absorbed. Matter therefore is comparatively a gossamer structure, subsisting in a very substantial medium. An estimate of the substantiality of the medium can be made from its magnetic energies, and it comes out almost incredibly large. If it is right to express it in terms of material properties (which is doubtful) its inertia comes out as of the order of 1,000 tons per cubic millimetre. While as to the elasticity, that is still more enormous, since it is equal to the density multiplied by the square of the velocity of light.

These values are barely conceivable, being so much higher than anything of which we have sensual experience. But still they should be capable of being measured and expressed; so the ether is a physical substance, with properties which can in time be ascertained; and if the estimate above given of the source of the vast energies involved is wrong (as it is sure to be inadequately and incompletely worded) subsequent investigation can correct it. Meanwhile we may assume that there is some truth underlying these modes of expression, a truth which we cannot at present formulate any better.

The constants embodying the physical properties of the ether though so huge are not infinite: its properties are finite but very simple and perfect. It is perfectly transparent, it dissipates no energy; otherwise the stars and the spiral nebulae could not be seen at their gigantic distances across space. There is no friction between matter and ether, otherwise a portion of matter isolated from the rest would cool down, and the planets would not continue forever in their courses unperturbed. The ether has nothing of what we call in matter viscosity or fluid friction. There is no real heat in the ether, nor any sound. Nothing but one simple type of propagation by waves goes on in free space, and that with a definite unchangeable velocity which is known as the velocity of light, the one fundamental and so to say absolute velocity in the universe.

Possible Structure.—The question arises as to what that velocity can be due to. The most probable surmise or guess at present is that the ether is a perfectly incompressible continuous fluid, in a state of fine-grained vortex motion, circulating with that same enormous speed. For it has been partly, though as yet incompletely, shown that such a vortex fluid would transmit waves of the same general nature as light waves—*i.e.*, periodic disturbances across the line of propagation—and would transmit them at a rate of the same order of magnitude as the vortex or circulation speed. There remains indeed a question of stability to be safeguarded, but in these days of quanta (*see* QUANTUM THEORY) stability considerations are apt to be deferred. Thus it appears possible that some day an extended hydrodynamics of a perfect fluid will explain all the physical properties of the material universe. *See* Lord Kelvin, "The Vortex Theory of Ether," *Phil. Mag.* (1887) and *Math. and Phys. Papers*, vol. iv. and passim; also G. F. FitzGerald, *Proc. Roy. Dub. Soc.* (1899), or *Collected Papers*, pp. 154, 238, 472.

This notion of a structure due to vortex circulation in a perfect fluid may be regarded by some as too material an idea, and it may have to be discarded; but it is the nearest approach that can be suggested to a pictorial image of the etheric constitution. Certainly no *structureless* fluid could transmit actual radiation. And certainly the ether is continuous and without viscosity or any dissipation of energy, and so in many respects is like an ideal fluid. More than that we cannot say, except speculatively, about its constitution.

Ether and Matter.—Meanwhile we must assume that the ether has a substantiality and a wave-conveying structure beyond our present clear imaginings, with parts of it modified in an unknown way into electrons and protons; that of these the atoms of matter are built up; and that the whole of material activity consists in the interactions of these minute electric charges, connected as they are by their lines of force and by radiation.

These electric charges, and the aggregates which they have built up are subject to what we experience or recognise as locomotion. The ether itself is stationary. Whether it is really infinite in extent, or whether, though boundless like the surface of a sphere, it is nevertheless finite, are questions which we cannot at present answer. There is no doubt that it extends beyond the farthest visible stellar object, and for all practical purposes is infinite. There is very little doubt that matter is not an alien substance, but is essentially composed of it, being built up of the electrons and protons whose constitution has not yet been ascertained, but which must somehow be constituted of ether, perhaps in some sense analogous to that in which a knot in a piece of string is constructed of string, or a vortex in air is composed of air, or the fibre of a muscle is still essentially flesh.

Einstein's Theory.—The theory of Relativity (*see* RELATIVITY) has led some people—not many of the leaders of thought—to doubt if the ether can really exist. It may be useful therefore to explain in what way the equations connected with that theory are to be understood physically. Newton expressed the laws binding the planets and suns together in terms of a hypothetical force acting between them, the same kind of force as we experience when a weight is supported above the earth; which force may therefore be taken as a fact of experience. But though the force is a fact, it is not explained: any expression in terms of action at a distance is necessarily incomplete.

Einstein was led by considerations of relativity to formulate a law of gravitation, not in terms of force or of action at a distance, but in terms of something in space, that is, in the ether, which results in a tendency of bodies to approach each other. It

might be called a warp in space, or it might be called by other names: the names do not matter. The thing that has to be expressed is that the presence of matter modifies its whole neighbourhood, causing a gravitational potential or virtual stress. And, until we know more about its intimate nature, the action of this modification is best expressed in terms of a differential equation which seeks to formulate abstractly, without physical hypothesis, the essence of what is really happening. None of the arguments which necessitate the existence of a medium are affected, but no name for it need be used, nor need the idea of a medium be introduced, for mathematical purposes. Mathematicians are quite able to work with abstract equations about quantities without physical implications or conceptions, as long as they remain purely mathematicians. They can reduce even geometry to arithmetic.

In a complete expression for the enlarged geometric "interval" between two points, the element of time must be introduced as well as the element of space, because they may be moving points. In other words geometry must be enlarged into kinematics, in order to express activities. The interval or line element between two neighbouring points may be expressed in polar co-ordinates r, θ, φ thus: $ds^2 = -dr^2 - (rd\theta)^2 - (r\sin\theta d\varphi)^2 + c^2dt^2$, a mode of expression devised by Minkowski, an enthusiast for this kind of four-dimensional treatment, where the fundamental etheric velocity c is introduced as a coefficient able to turn time into imaginary space, $icdt$. The emphasis on c, as an absolute geometric constant, is perhaps the most remarkable part of the Einstein-Minkowski conception, as a preparation for the building erected upon it.

But Einstein took a further step, introducing the gravitation potential as something which would modify the motions of matter, and introduced it not only into the element of time (as Newton might have done if he had used that notation) but into the element of radial distance also; so that if the points are in the field of a mass of matter m the Minkowski equation is:—

$$ds^2 = -\gamma^{-1}(dr)^2 - (rd\theta)^2 - (r\sin\theta d\varphi)^2 + \gamma c^2 dt^2$$

where $\gamma = 1 - 2P/c^2$, P being the gravitation potential at the place considered; which, if caused by a mass at a distance r, is $P = {}^{km}/_{r}$, with k as the Newtonian gravitation constant.

Here the coefficient γ occurs twice. If it occurred in the t term only it would be a mode of stating Newton's theory of astronomy, in differential instead of integral fashion; but this γ occurs in the r term also, as a result of the isotropy of the fourfold medium contemplated in this gravitational theory. This equation when elaborated gives, strangely enough, the outstanding progression of the perihelion of Mercury, and it also gives the double deflection for a ray of light passing near the Sun (doubled because the co-efficient γ occurs twice), which has since been confirmed quantitatively by observation of stars near an eclipsed sun. It likewise gives the shift of the spectral lines emanating from any sufficiently massive body, which has now been confirmed beyond the reach of reasonable controversy by observations on light coming from the companion of Sirius, which Eddington has astonishingly proved to be by far the most compact and densest material body at present known to science, so that it is characterized by an excessively high gravitational potential.

The beauty of these results is overwhelming; but the idea that any mathematical scheme is more than a powerful method of exploration, and that a universe can be thus constructed in which physical explanations can be dispensed with, involves too simple and anthropomorphic a view of nature. The things calculated, and the things observed, however brilliantly accordant, cannot exhaust reality; an explanation is bound to be sought, and ultimately attained, in terms of the partially recognised but largely unexplored properties of the entity which fills space.

Locomotion of Matter.—The locomotion of matter is perhaps the commonest fact of experience, and it seems strange that it should be in need of explanation. But since an atom of matter is composed of electric charges, the locomotion of those charges has to be considered more in detail. An electric charge in motion constitutes an electric current, and the path of every electric current is surrounded by rings of magnetic force. This magnetic field confers inertia or momentum upon the moving charge; so that mechanical impulse is necessary to start it moving; and also to stop the motion. If not stopped it will continue to move uniformly in a straight line until it encounters some deflecting or retarding agency.

But though locomotion can thus be stated and worked out electromagnetically, that cannot be regarded as an ultimate explanation of so familiar and apparently simple a thing. Moving matter is known to have kinetic energy; and the familiar expression $\frac{1}{2}mv^2$ is the type of its measure. But when we come to analyse this expression there are difficulties about it, which hardly need elaborate theory to bring out and emphasise. For when we try to specify the velocity of a body, in order to calculate its energy, we find it difficult to say what that velocity really is: we can only specify it with reference to something else, commonly with reference to the earth. But the earth itself is moving. Hence $\frac{1}{2}mv^2$ does not give the absolute energy, but only the energy relative to the earth or other frame of reference, as Newton implicitly recognised. What the velocity of a body is in space we have no means at present of ascertaining, having no universal standard of reference; and accordingly the usual expressions, though practically useful, are by no means ultimately satisfactory. Nor can a statement in terms of electromagnetism be considered as ultimate.

The fact is that locomotion does not seem to be a property of the ether; it appears to be affected by one speed and one speed only, namely, what we may imagine to be the speed of its internal circulation and are familiar with as the velocity of light. Yet a modified particle of ether, like an electron, can move from one place to another. The analogy of a loose knot slipping along a string may be helpful.

An electron even at rest has intrinsic energy, *viz.*, its electrostatic energy of constitution, which can be expressed in various ways, and which, when expressed in terms of mass and speed, is m_0c^2, m_0 being its inertia at rest. Its static energy is thus expressible as equivalent to that of a particle of certain mass m_0 or $2m_0$, moving with the speed c, the speed of light. To assist ideas, it might be thought of as a spinning motion; at any rate not locomotion.

When the particle is moved, the natural idea would be that this velocity c is increased, or that some addition is made to it. But according to the doctrine of relativity that is impossible: the velocity c is constant. The thing that changes is not c, but m. And the energy of a moving body is m_1c^2, where m_1 is greater than m_0. As the speed of motion increases, m_1 increases too; until at high speeds it grows fast, and, as the speed of light is approached, tends to become infinite. The factor, or ratio between m_1 and m_0, is $c/\sqrt{(c^2-v^2)}$. So when an identified portion of ether is in locomotion, it is not the fundamental speed that is changed, but the amount of modified ether, or modification of ether associated with that identified moving portion. And what we observe as the kinetic energy of a body is really $(m_1 - m_0)c^2$ or c^2dm. This is what we have hitherto recognized and called $\frac{1}{2}mv^2$, an expression which is only relative, and moreover is not exactly applicable to great velocities, such as we encounter in vacuum tubes and in radioactivity generally.

Short Summary of Present Knowledge.—To sum up our present position in more compact form, in order to put on record what may perhaps excite the interest or else the derision of posterity:—Assuming the Ether to be in some sense a substance, that is real and substantial, a genuine entity and not the mere emptiness which it superficially appears to be, the things that are known about it are these:—

(1) It is absolutely transparent and undispersive. In other words it quenches no light but transmits it undiminished in total intensity, though diluted by spreading, to and from the greatest distances known in astronomy. Moreover it transmits every kind of radiation at the same pace, whatever the wave-length, except in so far as it is interfered with by electricity or matter.

(2) It is absolutely devoid of viscosity. In other words it allows the motion of matter through it without any friction; it dissipates no energy and generates no heat. A serious attempt

made at Liverpool (University College) from 1890 to 1897 to detect a mechanical grip or cling between ether and rapidly moving matter, failed (as was more than half expected) to find any convective effect, even when the moving matter was strongly electrified or magnetised. (*Phil. Trans. Roy. Soc.*, 1893 and 1897.)

(3) Ether is the sole vehicle of radiation, that is of transverse disturbances periodic in space and time travelling at a definite and immense speed without any obvious destination, but it neither emits nor absorbs them. In other words it generates neither heat nor light; but it can receive these forms of energy from matter, and can convey and deliver them to other matter at a distance. Our sensory instrument, the eye, has long familiarised mankind with various practical aspects of this wonderful phenomenon.

(4) An electric field is another form of energy existing in the ether. For this we have no sense organ, and therefore know less about it, but its lines of force appear to be of the nature of strain. And probably the ether is the seat of all strain or potential energy. An electric field (like radiation) can only be originated by matter: its lines of force never terminate in ether, but they pass through ether along their whole extent. Insulating matter only modifies the lines, but conductors stop them.

(5) Another etheric form of energy is a magnetic field, which is certainly different from an electric field though somewhat similar. Magnetic lines of force are closed curves, and seem more intimately connected with the ether than with matter. But they interact with matter, and have thus displayed their existence by consequent attractions and repulsions.

(6) Electric and magnetic fields interact also with each other in free space, and thereby constitute radiation, in accordance with the Poynting formula that the flux of energy at every place is their vector product.

(7) Chemical affinity between atoms of matter is undoubtedly due to electric or magnetic attraction or both. And cohesion may be attributed to a residual chemical affinity between molecules. Thus the ether is indirectly responsible as a vehicle for all physical and chemical activity, and no one who believes in the ether has any doubt that it is responsible also for whatever is represented by the word "gravitation." What other functions this universal medium may be found to possess, and whether life and mind can be in any way associated with those functions, must be left to posterity to find out. Our serious surmise is that they are so associated, in a primary sense, and are temporarily manifested by secondary association with matter.

Steps Toward Further Knowledge.—Beyond definite knowledge, other guesses and working hypotheses have been made concerning the ether on the assumption that its properties can be partially expressed in terms of more or less familiar ideas. The property of inertia, so fundamentally possessed by matter, is doubtfully applicable to the ether. Even if matter turns out to be really modified ether, as many are beginning to expect, it is a question whether inertia arises as a result of the modification, or whether it is a property of the primitive substance which, by the materialisation, is individualised, localised and made manifest. If inertia can rightly be predicated of the ether itself, its value per unit bulk must be enormously greater than is exhibited by any kind of matter; for matter by its very constitution is certainly excessively porous, consisting as it does of minute particles far apart from each other in proportion to their size, whereas the ether must be as continuous as space itself. A molecular structure for the ether is not to be thought of, for its whole value as an explanation of facts depends on its continuity: separate particles with interspaces are appropriate to matter, but the whole problem of action at a distance would remain unsolved unless the particles are united into a coherent whole by something which has no gaps, and is responsible for cohesion, elastic rigidity and other properties of solids.

The fundamental units of measurement, the centimetre, gramme and second, have direct relation to matter, and it is doubtful if they are applicable to the continuous ether at all. If they are, then there are grounds for maintaining that the inertia of unit volume of ether is represented by a number of the order 10^{12}; while, since it certainly transmits the polarisable and therefore transverse vibration of light, it must on that view have a quasi-rigidity comparable to the number 10^{33}.

This elastic quasi-rigidity can be attributed to a continuous perfect fluid provided, and only provided, it is in an excessively rapid and fine-grained state of vortex motion; and Lord Kelvin showed that such a rotational or turbulent fluid could transmit transverse waves at a speed of the same order as the circulation velocity. This velocity c is now regarded as one of the unalterable constants of nature: it is the one definite measurement which has been made concerning the ether of space, and of itself is sufficient to show that space empty of matter is endowed with finite and measurable physical properties. We can measure the speed of light by aid of matter, because matter generates, absorbs, reflects, and otherwise interferes with it: we observe electricity and magnetism and every other manifestation of the ether by aid of matter; but unfortunately all the properties of ether itself, apart from matter, have hitherto proved completely elusive. None of our apparatus grips or gives us a foothold; so that some physicists claim that pragmatically the ether is a gratuitous hypothesis and need not really exist. It is quite true that physical calculations and discoveries can proceed without explicit reference to the ether, but when we come to philosophise and try to formulate the facts physically, it is clear that space must be endowed with physical properties and is therefore entitled to something more than a merely geometrical name. These properties are equally real inside matter, and radiation is everywhere conveyed by space: transparent material does not really convey light, it only allows the passage and reduces the speed.

So much for a transparent body, which must be an insulator because the electrons are tightly attached and not free to move. On the other hand, when the electronic constituents of matter are loose, not anchored to something heavier than themselves, the substance becomes a metallic conductor, and as such must be mainly opaque. A conducting film, or rarefied electric region, if it can transmit radiation at all can only do so in a peculiar manner. In an electrified region waves do not travel as in free space. Different wave lengths begin to be treated differently, for their speed is a function of wave length. An expression for their speed in that case is

$$v=\sqrt{(c^2+b^2\lambda^2)}$$

where b^2 is proportional to the electrical concentration. It turns out that b is the smallest frequency which such waves can have under the given conditions. Strangely enough the energy of the radiation is apt to lag a little behind these curious waves, for it travels at a speed called the group velocity c^2/v; and this may be slow when b^2 is big. The amount of energy is proportional to the frequency of vibration.

Interaction of Ether and Matter.—A part of space occupied by matter or electrical particles transmits radiation in a peculiar way. Treated in a statistical or average fashion, matter in which electric constituents are firmly attached to the atoms—so that it insulates when solid, and conducts chemically when liquid—has a refractive index μ which reduces the apparent velocity of light to c/μ; a simple consequence of wave theory which Foucault definitely verified; though the full explanation of such a reduced velocity is not simple. Maxwell's view of the dielectric constant, or specific inductive capacity of insulators, is that it must be nearly the same as μ^2. Transparent matter thus seems to load or increase the effective density of the ether by the amount μ^2-1, so that what is sometimes spoken of as bound ether—the portion appearing to cling to matter and move with it—is in such a substance $\frac{\mu^2-1}{\mu^2}$ of the whole: as Fresnel surmised and Fizeau experimentally verified by a successful experiment on the speed of light in moving water.

It must be admitted that this is only a superficial or tentative way of regarding the still partially unexplained reaction between matter and ether; for it must be understood that statistical or average forms of statement are never completely and finally satisfactory; they fill a gap in our knowledge for the time being,

and are true as far as they go. The Lorentz transformation, used by Relativists, arrives at the same result without philosophising about it or explaining it.

Question of Reversibility.—Every star is emitting energy at the expense of its own material, so that matter is gradually turning into radiation and passing into an unlocalised form in the ether. It may be said that, without the restriction of the quantum, whereby only whole units of energy can be radiated, all the energy of matter would pass into the ether and become radiation. A good deal does. The question naturally arises whether this process is reversible or not; *i.e.*, whether radiation can under any condition generate, in return, the fundamental ingredients of which matter is composed. This discovery has not yet been made. What we know of is that the jump of an electron generates radiation, of a frequency proportional to the energy of the jump; and that this same radiation, whenever absorbed, can cause another electron elsewhere to jump with the same energy. Hence the idea looks hopeful that a reversible process may be involved generally, in the interchange of energy between ether and matter, not only in this ordinary electronic laboratory case, but in the more violent clashes in the stars, where matter appears to be destroyed. May it not perhaps in some distant region be reconstituted, with a consequent great gain of gravitational potential energy, so as to render the cosmos permanent, and reduce the useful law of dissipation of energy to comparative insignificance?

Concluding Remarks.—We have seen that when we try to look at even so apparently simple a thing as locomotion, absolutely, we have to admit that varying speed means varying amounts of ether-modification in the identified portion of matter we are attending to; for we can only express absolute energy in terms of an ether constant c, which at first sight would appear to have nothing to do with it. The same constant enters into the composition of velocities. It is as if the normal constitutional etheric circulation trended or drifted in one direction, so as to constitute perceptible or available energy, much as the energy of a river or a gale of wind is a directed fraction of random molecular motions.

The same idea may be expressed magnetically by calling attention to the magnetic field surrounding a moving charge. At high speeds the magnetic field is strong; more substance is involved in it: and the additional spin (if that is the right term, for magnetism is usually thought of as a kind of spin) accounts for the additional energy. Why it should appeal to us as locomotion, and what the real meaning of locomotion is, are not so clear. This is only an illustration of the difficulty we experience when we come to probe the simplest thing to its depths. We have grown accustomed to certain aspects of the universe given us by our senses, but we do not fundamentally understand them. And when we come to probe the meaning of things deeply enough, we find ourselves up against difficulties of conception, toward the elucidation of which our senses give hardly any aid. What we are used to is mechanical movement; but the effort to explain things ultimately in that way is not easy, and may turn out to be not possible.

Meanwhile we take refuge in expressing these things in terms of electricity and magnetism; which is a step toward an explanation, and is useful in bringing out the difficulties which underlie every ultimate and absolute statement. The attempted absolute expression for static electric energy, mc^2, with the inertia m as the only variable, is a legitimate mathematical expression of actual facts. But the real meaning of c is, at present, a hypothesis: and what the real meaning of m is, must be regarded as still less known. Both these factors must have reference to the ether, and until we know more about the constitution of the ether we must be content to remain in a condition of provisional ignorance. We are led to regard the material universe as a substantial reality in various stages or varieties of internal activity. We may try to think of this activity as akin to a fine-grained vortex circulation in a continuous, incompressible, perfect fluid: beyond that we cannot at present go; nor are we clear about the exact meaning of these terms when applied to a medium of unknown constitution. When we understand the real and ultimate nature of electricity and magnetism we may hope to proceed further. Till then we must be content with proximate explanations and await the gradual illumination of further experience.

ETHER, in chemistry, any member of a certain class of substances (of which the well known anaesthetic, di-ethyl ether, commonly called "ether" or "aether," is one) composed of carbon, hydrogen and oxygen, and having the general formula, R·O·R′, where R·R′ = alkyl or aryl groups (*see* CHEMISTRY: *Organic*).

The term ether formerly included the esters (*q.v.*) of organic acids, such as acetic ether, now termed ethyl acetate. The true ethers are formed by elimination of one molecule of water from two molecules of the alcohols; the two hydrocarbon radicals are similar in *simple* ethers, and dissimilar in *mixed* ethers. They may be prepared by the action of concentrated sulphuric acid on the alcohols; alkyl sulphuric acids are first formed, and yield ethers on being heated with alcohols. The process is rendered continuous by running an alcohol slowly into the heated reaction mixture of alcohol and sulphuric acid. Benzenesulphonic acid has been used in place of sulphuric acid (F. Krafft, 1893). A. W. Williamson explained the mechanism of this action in 1850; in 1851 and 1852 he prepared di-ethyl ether (*v.* below) by the action of sodium ethoxide on ethyl iodide, and showed that all ethers possess the structural formula given above. They may also be prepared by heating the alkyl halides with silver oxide. Phosphorus pentachloride or halogen hydrides convert them into alkyl chlorides. With chlorine they yield substitution products.

Di-methyl ether, $(CH_3)_2O$, first obtained by J. B. Dumas and E. Péligot, 1835, is best prepared by heating methyl alcohol and sulphuric acid to 140° C and leading the evolved gas into sulphuric acid. The sulphuric acid solution is then allowed to drop slowly into an equal volume of water, when the methyl ether is liberated (E. Erlenmeyer and A. Kriechbaumer, 1874). It is a pleasant-smelling inflammable gas, condensing to a liquid which boils at −23·6° C. It is somewhat soluble in water and readily soluble in alcohol and concentrated sulphuric acid. It combines with hydrogen chloride to form a compound $(CH_3)_2O{\cdot}HCl$. *Methyl ethyl ether,* $CH_3{\cdot}O{\cdot}C_2H_5$, prepared from methyl iodide and sodium ethoxide, or from ethyl iodide and sodium methoxide, is a liquid boiling at 10·8° C. The homologous ethers are also liquids, with boiling points rising with increase of carbon content.

Di-ethyl ether, $(C_2H_5)_2O$, the *ether* of pharmacy is a colourless, volatile, highly inflammable liquid, of specific gravity 0·736 at 0°, boiling-point 35° C, and freezing-point −117·4° C, with a powerful characteristic odour, and a hot sweetish taste; it is soluble in ten parts of water, and in all proportions in alcohol; it dissolves bromine, iodine, and, in small quantities, sulphur and phosphorus, also the volatile oils, most fatty and resinous substances, guncotton, caoutchouc and certain vegetable alkaloids. A mixture of the vapour with oxygen or air is violently explosive. The making of ether by the action of sulphuric acid on alcohol was known in about the 13th century; and later Basil Valentine and Valerius Cordus described its preparation and properties. The name ether appears to have been applied to the drug only since the times of Frobenius, who in 1730 termed it *spiritus aethereus* or *vini vitriolatus*. It was considered to be a sulphur compound, hence its name sulphuric ether; this idea was proved to be erroneous by Valentine Rose in about 1800. Ether is manufactured by the distillation of 5 parts of 90% alcohol with 9 parts of concentrated sulphuric acid at a temperature of 140°–145° C, a constant stream of alcohol being caused to flow into the mixture during the operation. The distillate is purified by treatment with lime and calcium chloride, and subsequent distillation.

The presence of so small a quantity as 1% of alcohol may be detected in ether by the colour imparted to it by aniline violet; if water or acetic acid be present, the ether must first be shaken

with anhydrous potassium carbonate. Chromic acid oxidizes ether to acetic acid and ozone oxidizes it to ethyl peroxide. Ethyl peroxide also forms spontaneously in ether under many conditions of storage. This action is inhibited by certain metals, notably copper. In contact with hydrogen iodide at 0° C, it forms ethyl iodide, and with water and a little sulphuric acid at 180° C, it yields alcohol. It forms crystalline compounds with bromine and with many metallic salts.

Ether may be transported in iron drums, glass bottles and tin cans. Its principal use is in the manufacture of smokeless powder, organic synthesis as a solvent in analytical chemistry and for medicinal purposes. (*See* below.) No flames or sparking electrical equipment may be used in connection with the industrial application of ether.

Medicinal Uses.—(*See* ANAESTHESIA.) Applied externally, ether evaporates rapidly, producing such intense cold as to cause marked local anaesthesia. It is best applied as a fine spray, but ethyl chloride (*q.v.*) is generally found more efficient and produces less subsequent discomfort. Ether aids the absorption of fats and may be used with cod liver oil when the latter is administered by the skin. Ether, when subcutaneously injected, is perhaps the most rapid and powerful cardiac stimulant known, and is often employed for this purpose in cases of syncope under anaesthesia. Taken internally, ether acts in many respects similarly to alcohol and chloroform, but its stimulant action on the heart is much more marked owing to its rapid diffusion.

Chronic Poisoning.—A little more than a teaspoonful will produce a condition of inebriation, but the dose must soon be increased. The principal symptoms of chronic ether-drinking are a weakening of the activity of the special senses, and notably sight and hearing, a lowering of the intelligence and a partial paralysis of motion. The whole moral tone of the addict is lowered and he neglects his personal appearance. The effect is similar to chronic alcoholism in an advanced stage but the deterioration is more rapid and more marked.

ETHER, MUSIC FROM THE: *see* MUSIC FROM ELECTRIC OSCILLATIONS.

ETHEREGE, SIR GEORGE (*c.* 1635–1691), English dramatist and poet, was probably born about 1634–35, but practically nothing is known of his life except for a short period. Knowledge of his ancestry and early history is only derived from some chancery papers in the record office, from which it is gathered that his grandfather lived at Maidenhead and that he spelled his name as it is here spelled. He may have been educated at Cambridge, have studied law at one of the inns of court, and have lived some part of his early life abroad. In 1664 he was living in London, apparently quite unknown, when his first comedy, *Love in a Tub,* was produced at the Duke's theatre. This play marks the beginning of the specifically restoration comedy. It is partly in rhymed heroic verse, but the comedy scenes, with their play of wit, and their introduction of the "war of the sexes" theme, strike a new note in the history of the English drama. With the production of this play, Etherege leaped into fame. Thereafter he was one of the outstanding figures in the circle of Sedley and Rochester, and soon became an almost legendary type of the beau and wit of the day. More than 20 years after he had left London for ever the *Spectator,* to indicate the position Sir Roger de Coverley had held in his youth, said that he had often supped with Rochester and Etherege.

Three years of elegant idleness followed, before his next play, *She would if she could,* was produced at the Duke's house in 1677. "Lord!" says Pepys, "how full the house and how silly the play." He goes on to say that the actors were "out of humour," which may be partly explained by the nature of the play, which hovers rather indecisively between the formal comedy of the four lovers, and the farcical scenes where Jolly and Cockwood appear, which are more in the spirit of the Johnsonian comedy of humours. About this time he had an affair with the famous actress Mrs. Barry; she bore him a daughter who died in her youth. In 1668 he went to Constantinople as secretary to Sir Daniel Harvey, the English ambassador there. He returned to London in 1671, but published nothing but some occasional poems, drawing a rebuke for his laziness even from Rochester. At last in 1676 his last comedy, *The Man of the Mode,* appeared at the Duke's house. It was a great success, unlike the previous one, which appears to have fallen a trifle flat. But "Gentle George's" life was beginning to tell. A supreme picture of the life of the day, so much so that it set the fashion of "original-hunting" from which we have never escaped, it is yet a little less high-spirited and a little more savage than its predecessors. After this he continued his life as a man-about-town, and was involved with Rochester in the Epsom brawl which led to the death of Downes. Somewhere about 1679–80 he was married and knighted. The gossip of the day, our only authority, takes two forms; one that he married a fortune and so got a knighthood, the other that he was forced to purchase a knighthood to secure a fortune.

In 1685 he was appointed ambassador at Ratisbon, and his letters are preserved, so that at last he ceases to be a legend and becomes a living person for us. It is these letters that let us see the justice of his nicknames "Gentle George" and "Easy Etherege"; the essence of his letters is tolerance and good manners. It was not good form to make a fuss about anything, particularly your work. But this paraded idleness, which became affectation in his successors, is natural to him; his own nature is a summary of the ideal of the period. The only thing that roused him was the bad manners of the local burghers to a visiting actress in whom he was interested. That, as one might expect, he would not stand, and he raised all sorts of trouble until he got his apology. Exactly when he died we do not know, but it seems to have been in Paris, probably in 1691.

Etherege deserves to hold a more distinguished place in English literature than has generally been allotted to him. In a dull and heavy age, he inaugurated a period of genuine wit and sprightliness. He invented the comedy of intrigue, and led the way for the masterpieces of Congreve and Sheridan. Before his time the manner of Ben Jonson had prevailed in comedy, and traditional "humours" and typical eccentricities, instead of real characters, had crowded the comic stage. Etherege paints with a light, faint hand, but it is from nature, and his portraits of fops and beaux are simply unexcelled. No one knows better than he how to present a gay young gentleman, a Dorimant, "an unconfinable rover after amorous adventures." His genius is as light as thistle-down; he is frivolous, without force of conviction, without principle; but his wit is very sparkling, and his style pure and singularly picturesque. No one approaches Etherege in delicate touches of dress, furniture and scene; Sir Fopling, for example, "He was yesterday at the play, with a pair of gloves up to his elbow, and a periwig more exactly curled than a lady's head newly dressed for a ball"; he makes the fine airs of London gentlemen and ladies live before our eyes even more vividly than Congreve does; but he has less insight and less energy than Congreve. Had he been poor or ambitious, he might have been to England almost what Molière was to France, but he was a rich man living at his ease, and he disdained to excel in literature. Etherege was "a fair, slender, genteel man, but spoiled his countenance with drinking." His contemporaries all agree in acknowledging that he was the soul of affability and sprightly good-nature.

The life of Etherege was first given in detail by Edmund Gosse in *Seventeenth Century Studies* (1883). His works were edited by A. W. Verity, in 1888, and by H. F. B. Brett-Smith (Percy Reprints, no. 6, Oxford, 1927); *see* B. Dobrée, *Restoration Comedy* (Oxford, 1924). (E. G.)

ETHICAL MOVEMENT, THE. The object of the Ethical Movement is to emphasize the moral factor in all the relations of life in such a way that morality may be regarded as the fundamental and abiding part of religion, and therefore the true basis for religious union; for the noblest religious beliefs of all civilized peoples, when traced to their source, are found to be inferences from the facts of moral life.

Never before has there been an attempt to found a religious organization in which all can unite, and yet, such is not only a possibility, but a necessity, if progress in the moral life is to be realized.

Foundation of the Movement.—The ethical movement was initiated in the United States in 1876 by Felix Adler, Ph.D. of

Columbia University, a young Jew then being trained as a Rabbi. As a young man while completing his studies in Berlin, he was impressed by the sublimity of the works of Immanuel Kant, with whose philosophy he at that time identified himself. He was also influenced by his reading of the *Die Arbeiterfrage* of Friedrich Albert Lange. In a glow of enthusiasm his first action on returning to America consisted, as he says "in founding among men of my own or nearly my own age a little society, which we ambitiously called a Union for the Higher Life, based upon three tacit assumptions:—sex purity, the principle of devoting the surplus of one's income beyond that required for one's own genuine needs to the elevation of the working classes, and, finally, continued intellectual development."

Ethical Philosophy of Life.—Dr. Adler later broke with the Hebrew Religion, although friends urged him to maintain outward conformity in order to adapt the truth of the old faith to modern conditions. But he was too honest for this, and felt, moreover, that what was of real value in Hebrew or in any other religion needed to be "re-stated and fitted into a larger synthesis." He compared religious growth to the growth of a tree and said "to expect that development should continue along Hebrew or Christian lines was like expecting that a tree would develop along one of its branches. There is a limit beyond which the extension of a branch cannot go. Then growth must show itself in putting forth a new branch."

The first actual Ethical Society was inaugurated in New York on May 15, 1876, and the bulk of it, in the words of Dr. Adler, "consisted of what would be called average people, especially of fathers and mothers who felt the need both for themselves and their children of something to take the place of the consecrating influence of the old religions." This desire for a consecrating influence expressed itself in the initiation of very simple Sunday services, which were without prayer or ritual and were preceded by beautiful music to induce a suitable atmosphere, the most important feature being the address. Dr. Adler's ideals as to the qualifications necessary for an ethical speaker are so high that he expressly declares:—"that he shall give his whole life to the problems of ethical living, having no professional or business interests in competition with his dedication to these problems. . . . The platform of an Ethical Society is itself the altar, the address must be the fire that burns thereon."

Societies in America.—The Society founded in 1876 prospered, and has distinguished itself by organizing a school where pupils are educated from the kindergarten to the university stage; a large number of free places are open to children of requisite ability, irrespective of race or colour.

There are now six Ethical Societies in America, viz.—The New York Society for Ethical Culture, Chicago Ethical Society, Philadelphia Society for Ethical Culture, St. Louis Ethical Society, Brooklyn Society for Ethical Culture, and the Boston Ethical Society. These are federated into the American Ethical Union, whose object is "To assert the supreme importance of the ethical factor in all relations of life, personal, social, national and international, apart from any theological or metaphysical considerations."

British Ethical Societies.—The New York Society for Ethical Culture is regarded as the parent of the British Societies. The effort has not met with the same popular success in Great Britain as in America, where religious thought appears to have been far less hampered by unfavourable social conditions and traditional influences than has there been the case. The first English Ethical Society may be said to have been founded in 1888, when Dr. Stanton Coit became minister of the South Place Religious Society after the resignation of Moncure Daniel Conway. Dr. Coit had been attached to Dr. Adler's Society in New York and his aim was to reproduce in England the main features of the American ethical culture movement, with such modifications as were needed by the circumstances and traditions of the older country. At his suggestion the Society was called the South Place Ethical Society. In 1892 Dr. Coit retired from South Place and later in the year became Lecturer and Organizer for the newly-formed West London Ethical Society.

In 1895 the then existing North, South, East and West London Societies took steps to become federated, the Union of Ethical Societies being formed in 1896 and finally incorporated as the Ethical Union in 1928. Its main object is:—"To promote by all lawful means the study of ethical principles; to advocate a religion of human fellowship and service, based upon the principle that the supreme aim of religion is the love of goodness, and that moral ideas and the moral life are independent of beliefs as to the ultimate nature of things and a life after death; and, by purely human and natural means, to help men to love, know, and do the right in all relations of life."

The English ethical movement has included amongst its supporters and sympathizers Professors Leslie Stephen, J. H. Muirhead, Bernard Bosanquet, and Alexander and J. S. Mackenzie, as well as other distinguished moral philosophers and prominent men of science and letters, some of whom have been presidents of the Union. The Secular Education League was founded in 1907 as the result of a public conference convened by the Union in 1906. It regards religion as a personal and private matter which all should be free to pursue in a private capacity. In 1911 the Union assisted in promoting the first Universal Races Congress in London; it attracted world-wide attention and 17 Governments were officially represented.

A series of conferences of modern religious thinkers were convened by the Union in 1920, 1921 and 1923, at which Professors Gilbert Murray, J. B. Bury and L. T. Hobhouse presided. Distinguished speakers, representing many diversities of faith, attended to address the meetings.

Summer Schools for the consideration of vital social and moral problems were arranged in 1926, 1927 and 1928, experts being invited to speak on the subjects under discussion. A constant propaganda has been sustained by the English Ethical Union. It has produced, either directly or in association with publishers, many pamphlets, leaflets and books in advocacy of the principles of the Movement.

The English Ethical Societies are as follows:—The Ethical Church, Bayswater, the Forest Group of the Ethical Movement, Hampstead Ethical Institute, South London Ethical Society, South Place Ethical Society, Wimbledon Ethical Society, The Women's Group of the Ethical Movement, and The Young People's Group of the Ethical Movement. They are akin both in thought and method to the Ethical Societies in America, with whom a close relationship is maintained.

ETHICS is the systematic study of the ultimate problems of human conduct (from Greek ἦθος, character, or ἔθος, custom); also called *Moral Philosophy* (from Lat. *mores*, customs).

The Scope of Ethics.—Human conduct may be studied in many different ways. It may be observed and described in a purely external manner, in the way in which the behaviour of lower animals is sometimes studied; and this is the way in which behaviourism (*q.v.*) deals with human conduct. It may be studied in relation to the mental processes which precede or accompany it; this is the way in which psychology and common sense usually deal with it. It may be studied in relation to physical and social environment, as is done to some extent in biology, anthropology and sociology. The results of these and similar studies are important for ethics. But the problem of ethics is essentially different. Unlike the above-mentioned studies, it is not concerned mainly with bare facts but with values, with estimates. This is usually expressed by saying that ethics is not a positive science but a *normative science*—it is not primarily occupied with the actual character of human conduct but with its ideal, not so much with what human conduct is as with what it ought to be. It should be noted, however, that even ideas of what human conduct ought to be may be studied in a positive or natural-history spirit. They are so studied to some extent in sociology

(*q.v.*) and comparative ethics (*q.v.*), in which moral ideas as well as customs are correlated with other cultural conditions. In ethics proper the standpoint taken is, as far as is humanly possible, that of an ideal humanity capable of rising above the common limitations of time and place. To maintain such a point of view is no easy matter, even for philosophers, whose special business it is to rise above the prejudices of the multitude. And Nietzsche has complained, not without some justice, that the moral philosophers of Christendom have attempted little, if anything, more than a rational systematization of Christian preaching (the practice of Christendom would baffle any such attempt at rational systematization). Many moral philosophers, indeed, have stated explicitly that the business of ethics merely consists in clearing up current moral conceptions and unfolding the ultimate presuppositions involved in them, and that it is not its function to discover new moral ideas. It may be remarked that even the ethics of Aristotle attempted no more, although he was not bound by anything like this authority, and the traditions of the Christian Church. It is only occasionally in the history of ethics that Sophists or Sceptics impugn the validity of traditional moral ideas, or that a Spinoza or a Nietzsche ventures to proclaim new ideals of conduct. The present article, however, is not concerned with the history of ethics (*q.v.*) but with the main problems of ethics. These problems turn chiefly on the following conceptions: (1) the highest good of human conduct, or its ultimate ideal aim, which may serve as the ultimate standard of right conduct; (2) the origin or source of our knowledge of the highest good or of right and wrong; (3) the sanctions of moral conduct; (4) the motives which prompt right conduct. Another problem discussed by moral philosophers is that of the freedom of the will; but as this is dealt with under FREE-WILL it will not be considered in the present article.

THE HIGHEST GOOD

The oldest, and in some ways the most important, ethical problem is that relating to the supreme good or ultimate end of human conduct. Many human activities are admittedly directed to ends or purposes that are not regarded as possessing value in themselves, but as means to ulterior ends which confer on them a derivative value. One may do strenuous physical exercises or take long walks merely in order to keep physically fit; one may play chess or solve cross-word puzzles in order to exercise and improve one's intelligence, or in order to divert one's thoughts from cares and worries; one may try hard to make money in order to provide for one's dependents, or in order to carry out some other philanthropic scheme. But even these ulterior aims may not be valued as final ends; one may be prepared to sacrifice them to some higher end. The individual may at a supreme crisis be willing to sacrifice himself and his family to some great cause such as honour, or justice, or patriotism, or humanity. Yet some end or aim there must be (so it is commonly assumed) which is ultimate and not subordinate to anything else. Such an ultimate end, whatever it may be, is usually called the *summum bonum*, or highest good. It is an old ethical tradition that there is such a highest good; and that this highest good is *happiness*. (The view that happiness is the *summum bonum* is known as *Eudaemonism*.) There are, however, very different conceptions about the nature and claims of happiness as the ultimate end of human conduct. Moreover, other ultimate ends have been formulated, such as *perfectionism*, or *duty* for duty's sake, and, in intimate connection with this, the *good will* as the highest good. All these conceptions must be briefly considered.

Happiness As the Highest Good.—The popular moral maxims of all times and climes testify to the widespread belief that in the last resort what man really seeks is happiness, and that all his other pursuits are directed (though sometimes mistakenly) to this end. Popular moralizing for the most part either points out the right means to happiness or utters a warning against the wrong means. Hence the prudential character of popular ethics. Psychologically the assumption that happiness is what men always seek either directly or indirectly is open to serious criticism. Generally speaking, happiness is the consequence of the attainment of some desired end, the satisfaction of some felt need. It is not usually either the actual end or object desired, or even the conscious purpose for which something else is sought. For the most part it is only people devoid of interest in things, and so deprived of the satisfaction of realizing, or at least advancing some cause or other, who voice a longing for happiness, or their grievance against its elusiveness. But even if this objection be waived as something calling for a more careful reformulation of the eudaemonistic *summum bonum* rather than for its rejection, the question naturally arises as to *whose* happiness is to be sought. To this question three different answers are possible, and have actually been given. It may be held that each individual should seek his own happiness. This theory is known as *Egoistic Eudaemonism.* On the other hand it has been maintained that the end to be pursued is the happiness of mankind as a whole or at least of the community of which the individual concerned is a member. This theory is known as *Utilitarianism.* A third answer that has been suggested, though not very seriously, is that the individual should always pursue the happiness of others, not his own happiness. This theory is known as *Altruism* or *Altruistic Eudaemonism.* These views will now be considered in turn.

Egoistic Eudaemonism.—In its crudest form this theory identifies happiness with physical pleasures. (A theory which identifies happiness with physical pleasure or sensuous enjoyment is called *Hedonism.*) In its maturer form egoistic eudaemonism (indeed every form of eudaemonism) attaches a higher value to pleasures of the mind (that is, pleasures derived from the pursuit of knowledge, art, etc.) than to those of the body; and in its highest form, egoistic eudaemonism identifies individual happiness with that which results from the fullest development of a highly artistic or spiritual personality. By a curious paradox egoistic eudaemonism is apt to become ascetic in character when it takes on a religious complexion. The individual is then so bent on securing his salvation at all costs that he eschews all ordinary pleasures, and sacrifices worldly happiness on the altar of an other-worldly blessedness.

Universalistic Eudaemonism or Utilitarianism formulates as the highest good the happiness of the community, not merely that of the agent himself. According to egoistic eudaemonism the agent is only interested in others in so far as they are of service to him in some way or other. According to utilitarianism, on the other hand, the agent should not claim any privileges for himself—no individual must count as more than one, and the happiness to be aimed at is the greatest happiness of the greatest number. There are obvious difficulties in such a theory. Even if it were true, as Bentham believed, that pleasures differ only quantitatively, not qualitatively, that pushpin and poetry afford the same kind of pleasure, even so it would be difficult to choose, on the utilitarian principle, when the same quantity of happiness might be afforded to alternative groups of people. Why prefer the happiness of A, B, C to that of X, Y, Z? But, as J. S. Mill admitted, pleasures are not of the same kind. Moreover they cannot be reduced to a common denominator. This difficulty is inherent in every form of eudaemonism. But in so far as it is real, it is impossible to construct a calculus of pleasures such as is indispensable to utilitarianism. Still the practical difficulties of the doctrine must not be exaggerated. The problems of life and conduct are vastly more complicated than the problems of arithmetic, whatever ideal one may set himself. And utilitarianism, whatever its shortcomings may be, proved itself an effective instrument in the march of social democracy—and that was the main point with its founders.

Altruistic Eudaemonism or Altruism, when the term is not used as synonymous with utilitarianism, demands the pursuit of the happiness of others at the expense of one's own. It is a more positive formulation of the familiar doctrine of self-sacrifice. Every ideal of life involves an element of self-repression, and self-denial is one of the conditions of self-fulfilment. But the pure altruism with which we are here concerned can hardly be considered seriously. If the happiness of the agent himself has no value, how can the happiness of others be of value? If it be urged that self-devotion to others, in so far as it is reciprocal,

is a sure way of securing the happiness of everybody, then it is only utilitarianism in a disguised form, and expressed in a manner which recalls the famous island, the inhabitants of which maintained themselves by doing each other's washing. The doctrine of altruism and self-sacrifice is only too intimately associated with incompetent state-craft. Those who lack sufficient wisdom and insight so to work the social and political machine as to enrich the life of the citizens usually head for the kind of disaster which necessitates the sacrifice of the lives of the citizens in order to save the machine and the mechanics.

Perfection As the Highest Good.—Perfectionism is the theory which maintains that the highest good of human conduct is the fullest development of all the capacities of man in so far as these can co-exist in an harmonious whole. This may be expressed in yet another way. Man, like everything else, has certain latent potentialities. Different things have different kinds of potentialities, according to which we array them in a certain order of merit. Living plants have more potentialities than inert matter, animals are superior to plants, and man to animals. The precise limits of human potentialities cannot, of course, be determined in advance. But the high attainments of gifted individuals serve as milestones on the path of human progress, and encourage the imaginative construction of ideals of human life and character. Such ideals become standards of perfection, and the attainment of such perfection, or at least the earnest endeavour to attain it as far as in us lies, is what the theory of perfectionism regards as the highest good of human conduct.

Egoistic, Universalistic and Altruistic Perfectionism.—The question as to *whose* perfection is to be aimed at by the moral agent is clearly answerable, at least theoretically, in the same three ways as the corresponding question relating to eudaemonism or happiness. The perfection sought might be that of the individual agent, or of mankind (or at least the community) as a whole, or of people other than the agent himself. We should thus get egoistic, universalistic and altruistic perfectionism corresponding to the three forms of eudaemonism. But the universalistic form is the only one worth serious consideration. Even in the case of eudaemonism it may be urged that the universalistic form is the only tenable one, inasmuch as ideal happiness on the part of any individual is inconceivable in a *milieu* of unhappiness. But the contention is much stronger in relation to perfectionism. An individual may grow towards perfection in virtue of his struggle against imperfection and evil. But it is more than doubtful whether the attainment, the realization of perfection, is conceivable except in a perfect society. That is why the upholders of perfectionism sometimes postulate, as the metaphysical basis of their moral philosophy, the existence of a society of spirits as an essential part of the cosmic order. Actually, it is true, one may meet with a supreme egoist, such as Goethe is alleged to have been, who is so absorbed in his own development as to "pass by" all else. It is also not unusual to find very imperfect people trying to exercise a "moral influence" on others without attempting to heal themselves. Ethically, however, such cases are of little or no significance.

Perfectionism and Eudaemonism are not entirely opposed to each other. In fact, they have certain features in common. In the first place, perfectionism may be said to embrace eudaemonism to some extent inasmuch as perfectionists usually maintain, and, from a psychological point of view, rightly maintain, that whatever contributes to human perfection is generally also conducive to human happiness, while that which retards human development also brings unhappiness. Again, eudaemonism and perfectionism tend to estimate moral conduct by its results. According to eudaemonism, conduct is good or right if it promotes happiness; it is bad or wrong if it leads to unhappiness. According to perfectionism, conduct is good or right if it promotes the development of human potentialities; it is bad or wrong if it hinders it. Apart from such results, it would appear that human conduct as such could not be described as good or bad, as right or wrong. Lastly, the highest good, which, of course, is also the standard of conduct, as conceived by both eudaemonists and perfectionists, is such that it would be pursued quite spontaneously without the sense of "obligation" or "duty" frequently associated with right conduct. Hence the tendency of both eudaemonist and perfectionist ethics to become mainly descriptive. In the case of eudaemonist ethics this tendency is seen clearly in so-called psychological hedonism, which takes its stand on the alleged fact that men actually do pursue pleasure as the ultimate good. In the case of perfectionist ethics this same tendency is clearly observable in the ethics of Spinoza, which aimed "neither to revile nor to deride but to understand" human conduct. One consequence of this is what may be described as the predominantly intellectual character of eudaemonist and even more so of perfectionist ethics.

Duty As the Highest Good.—In contrast with both eudaemonism and perfectionism, which make the moral worth of conduct depend on its results, an attempt has been made, notably by Kant, to associate moral value with the immediate springs of conduct. This attempt is inspired to a great extent by what may be crudely described as a sense of constraint that is frequently associated with moral behaviour, and which is regarded by upholders of this view as of the very essence of right conduct. Right or good conduct, in other words, must be judged by the sense of duty which prompts it, not by the consequences which result from it. There is, according to this view, a "categorical imperative," an unconditional law of duty, which demands obedience, whatever the consequences may be, and implicit obedience to this categorical imperative is the highest and only ultimate good. "Nothing in the world," says Kant, "is good except the good will." In order to make his theory plausible, and save it from the chaos of the Babel of voices in which the categorical imperative finds utterance in different cases (when it finds utterance at all), Kant had to postulate a metaphysical moral order, on the one hand, and to empty the categorical imperative of all definite content, on the other hand. All that the categorical imperative bids us, according to Kant, is this: "act only on that principle which thou canst at the same time will to become a universal law." Apparently the essence of evil consists in treating one's own case as exceptional. *Nomism* (as this theory might be called) savours perhaps too much of the Prussian drill-sergeant's love of the uniform and of obedience to be greatly in favour with an age that has a touching faith in freedom and democracy. Moreover, there are certain psychological considerations which seem to shake the very basis of the nomistic theory of duty for duty's sake. There are some people who have never heard the categorical imperative even in the modest form of a still, small voice. Some of those who have heard it are prone to identify it with a familiar and usual form of constraint that heredity, education and social environment are apt to make habitual in most mortals. Lastly, sentiment itself has a way of powerfully prompting various kinds of action in relation to its objects; and most people, probably all, for one reason or another, or even for no reason at all, possess, or are possessed by, sentiments for various objects, whose impelling promptings may easily be mistaken for the commands of the categorical imperative. Of course, there is a stage in the education of everybody when discipline and the inculcation of a sense of duty may be not only valuable but necessary. In moral *philosophy*, however, as distinguished from moral pedagogy, one is concerned with the mature, reflective person; and the moral ideal is that of a race of people who are so mastered by high ideals that they do their duty and know it not, rather than of a race of well-drilled creatures of habit.

THE KNOWLEDGE OF GOOD AND EVIL

How do we know what is good or evil, right or wrong? The principal answers to this question are rather mixed, combining more or less different epistemological points of view. But if their predominant element be considered, then three main answers may be distinguished, namely, the *empirical*, the *rational* and the *intuitionist*.

Empiricism.—This stresses chiefly the actual experience of mankind. Ancient and modern appeals to the *consensus gentium* (the general agreement of mankind) are a case in point. Another case is that of the modern biological answer as formulated, say,

by Spencer, according to whom our moral judgments, however self-evident they may appear to us, are really the result of certain habits which have been acquired by mankind in the course of evolution as they learned by experience to adapt themselves to their environment. In so far as moral habits and moral ideas are different among different peoples, the empiricist would endeavour to obtain a general standard of right conduct by a careful comparison and sifting of the relevant facts. As this task is full of difficulties, empiricist ethics rather tends towards relativism or the denial of a really universal objective moral standard.

Rationalism or a Priorism.—This stresses the sufficiency of reason to determine what is good or evil, right or wrong, more or less independently of actual experience (i.e., *a priori*). To some extent Kant may be regarded as an ethical rationalist, though it is perhaps better to class him as an intuitionist. A much older example of ethical rationalism of a rather different type is the theory of Socrates that all virtue is knowledge. Plato and Aristotle, Spinoza and Hegel may also be classed among ethical rationalists. Even Kant, however, found it impossible to put any content into the categorical imperative, or to formulate anything very definite as the discovery of reason. To judge from what mostly happens in the practical affairs of daily life it would appear that our everyday moral judgments are prompted by something too vague to be dignified by the names of empirical method or of method of reason. Owing to its vagueness it is usually described (as such vague experiences commonly are described) as a *feeling*, or some kind of feeling. This description is probably intended to stress the character of *immediacy* (as distinguished from discursiveness) rather than its *affective* character. The theory of *intuitionism* tries to do justice to the apparent immediacy of moral judgment without deriving it from feeling as such. It must be remembered, however, that some moral philosophers have held that moral judgment is essentially a matter of feeling, like the aesthetic appreciation of beauty.

Intuitionism in ethics, then, is the theory that man has an immediate apprehension of moral value as such. Some intuitionists maintain that what is intuited is the ultimate moral law (say, Kant's categorical imperative). Others hold that we intuit the moral character of certain general types of conduct or of motives. Yet others are of the opinion that what is intuited is the moral value of each separate act or feeling either absolutely or at least relatively to some other act or feeling. But intuitionists differ among themselves not only with regard to the object of intuition but also with regard to the intrinsic psychological character of the intuitive process itself. Some describe it as a kind of perception, and speak of a "moral sense" analogous to other kinds of sense-perception. Others regard it as a function of reason. (Such intuitionism is hardly distinguishable from rationalism; hence the above remark about Kant.) Others again, as already noted, conceive it to be a kind of feeling, similar to that of aesthetic appreciation.

In some ways intuitionist ethics, like empirical ethics, rather tends towards ethical relativism. If his intuition is the final tribunal of moral judgment for each individual, it is clearly possible for different individuals to judge differently. Kant, it is true, held that "an erring conscience is a chimera." But in order to make this view plausible he had to invent an elaborate metaphysical substructure. Pope was probably nearer the truth when he suggested that "our consciences are like our watches. None go just alike, yet each believes his own."

THE SANCTION OF MORALITY

It has already been remarked above that moral conduct is commonly associated with a sense of duty to do certain things and to abstain from certain others. The question then naturally arises concerning the authority of this sense of duty to command or to prohibit actions as the case may be. This is the problem of the *Sanction of Morality.* The problem does not arise for some ethical theories. At least, it is not equally urgent for all of them. For eudaemonists and perfectionists, *e.g.*, the highest good is something so intrinsically alluring that the question of a moral sanction, if it is raised at all, can be adequately answered by saying that the *summum bonum* is its own sanction, its own authority. The problem is most urgent in those cases in which morality is regarded as something imposed upon man by some outside authority. At first sight, this would appear to be the case with Kant's categorical imperative. Kant, however, insisted on the autonomy of conscience. He regarded the moral law as *self-imposed* by the rational will of man who, *qua* a person, identifies himself with the moral law, which thus carries its own sanction with it. Kant's view, however, requires the metaphysics of a moral world-order valid for all rational beings, and such a metaphysics is remote from the thought of the ordinary moral person. Generally speaking, most people who are moral lean on some outside authority as their moral sanction. The three most important sanctions of the type with which we are here concerned are the *religious, political* and *social sanctions.*

The *religious sanction* is operative when morality is based on the authority of God or of the Church. (Strictly speaking, what is called the authority of God is always the authority of some church which claims to speak in His name.) In this case moral imperatives are looked upon as the commands of God, these imperatives being sometimes regarded as purely arbitrary. According to this view, if God had chosen to command what He has prohibited, or to prohibit what He has commanded, then what is now right would have been wrong, and what is now wrong would have been right. Nothing is either good or bad but God makes it so. For those who accept such a sanction there can be no ethics, no rational or philosophical account of morality, for all is arbitrary.

The *political sanction* is operative when the state is regarded as the authority that is empowered to decide what the citizen ought to do or avoid. The acceptance of this sanction tends to efface the distinction between legality and morality. It is also, as a rule, intimately connected with a eudaemonistic (generally utilitarian) ethical theory, for the aim of the state (except it be theocratic, like Geneva in the days of Calvin) is really to promote the temporal happiness of its citizens.

The *social sanction* is that exercised by society or one's social environment, in a less formal and less explicit manner than is done by the State as a political organization. There are social customs and traditions which carry much weight though not embodied in laws or regulations of the legislative body.

It is, of course, possible for all the above-mentioned sanctions to carry authority for the same person. In a theocratic state it would perhaps be so inevitably.

Any theory of morality which treats it as resting on its own authority is called *autonomous;* theories which base morality on any authority outside itself are usually called *heteronomous.* Strictly speaking, of course, it is the morality or the moral law, not the theory of morality, that is either autonomous or heteronomous.

THE MOTIVE OF MORAL CONDUCT

The problem of the sanction of morality is intimately connected with that of the *motive* of moral conduct; in fact they are two aspects of one theme. Sanctions are chiefly of practical importance in so far as they furnish motives. The natural inclinations of man are not, as a rule, strictly moral. Hence the sense of constraint, of external pressure, so frequently associated with the performance of duty. The question thus arises inevitably as to how man comes to conform to moral dictates in spite of his natural inclinations. This is the problem of *motives,* meaning by motives whatever induces one to adopt a certain course of action. The answers to this problem are various, and are intimately connected with differences in the views adopted in relation to some of the other ethical problems already considered. Egoistic eudaemonists naturally incline to say that the chief motives of moral conduct are the hope of obtaining some happiness and the fear of pain or misery. And to some extent this view is really implicit also in all ethical theories that formulate external sanctions of morality. The religious sanction is apt to build upon the personal hope of heaven and the personal fear of hell; though there is such a thing as a love of God that is entirely free from such

considerations. The political sanction may easily be identified with the fear of the police and punishment on the one hand, and the hope of political advancement on the other. Similarly, the social sanction may often assume the form of a fear of social ostracism of one kind or another, and the hope of finding favour with one's fellows who may advance one's ambitions. Of course, this need not be so; no doubt there are some who love their country or their community without any ulterior considerations. From the point of view of utilitarianism the political and social sanctions may provide the bases of quite satisfactory moral motives. Similarly, with universalistic perfectionism.

It is quite different with nomism, the theory of duty for duty's sake. In its rigorous form it approves no motive except that of respect for the moral law. Personal fear and hope it would condemn as selfish motives; and actions prompted by political or social motives it would characterize as "legal" but not as moral. This severe attitude of Kant was ridiculed by the poet, Schiller, who was otherwise a devoted admirer of the philosophy of Kant. And, most remarkable of all, Kant himself could not escape entirely the natural desire of man for happiness, on which he actually based the postulates of the existence of God and of the immortality of man, so that those who do their duty for duty's sake may yet reap their reward, at least hereafter in a better world.

Note.—The preceding account of ethics only gives a sketch of the main ethical problems and their solutions. The article, ETHICS, HISTORY OF, gives the historical setting of the problems and their solutions, and discusses them more fully. The adequate study of these problems, however, requires also some insight into the whole philosophical system of each moral philosopher, such as will be found in the articles under the names of the leading moral philosophers.

ETHICS, HISTORY OF. The following historical sketch traces the main lines of development of ethical theory. Fuller details will be found in separate articles devoted to special subjects. The most important thinkers whose names occur in this historical outline have separate biographical articles devoted to them.

GREEK AND GRAECO-ROMAN ETHICS

The Pre-Socratic Philosophers.—The ethical speculation of Greece, and therefore of Europe, had no abrupt and absolute beginning. The naïve and fragmentary precepts of conduct, which are everywhere the earliest manifestation of nascent moral reflection, are a noteworthy element in the gnomic poetry of the 7th and 6th centuries B.C. Their importance is shown by the traditional enumeration of the Seven Sages of the 6th century, and their influence on ethical thought is attested by the references of Plato and Aristotle. But from these unscientific utterances to a philosophy of morals was a long process. In the practical wisdom of Thales (*q.v.*), one of the seven, we cannot discern any systematic theory of morality. In the case of Pythagoras, conspicuous among pre-Socratic philosophers as the founder not merely of a school, but of an order bound by a common rule of life, there is a closer connection between moral and metaphysical speculation. The doctrine of the Pythagoreans that the essence of justice (conceived as equal retribution) was a square number, indicates a serious attempt to extend to the region of conduct their mathematical view of the universe; and the same may be said of their classification of good with unity, straightness and the like, and of evil with the opposite qualities. Still, the enunciation of the moral precepts of Pythagoras appears to have been dogmatic, or even prophetic, rather than philosophic, and to have been accepted by his disciples with an unphilosophic reverence as the *ipse dixit* of the master. Hence, whatever influence the Pythagorean blending of ethical and mathematical notions may have had on Plato, and, through him, on later thought, we cannot regard the school as having really forestalled the Socratic enquiry after a completely reasoned theory of conduct. The ethical element in the "dark" philosophizing of Heraclitus (*c.* 530–470 B.C.), though it anticipates Stoicism in its conceptions of a law of the universe, to which the wise man will carefully conform, and a divine harmony, in the recognition of which he will find his truest satisfaction, is more profound, but even less systematic. It is only when we come to Democritus, a contemporary of Socrates, that we find anything which we can call an ethical system. The fragments that remain of the moral treatises of Democritus are sufficient, perhaps, to convince us that the turn of Greek philosophy in the direction of conduct, which was actually due to Socrates, would have taken place without him, though in a less decided manner; but when we compare the Democritean ethics with the post-Socratic system to which it has most affinity, Epicureanism, we find that it exhibits a very rudimentary apprehension of the formal conditions which moral teaching must fulfil before it can be treated as scientific.

The truth is that no system of ethics could be constructed until attention had been directed to the vagueness and inconsistency of the common moral opinions of mankind. For this purpose was needed the concentration of a philosophic intellect of the first order on the problems of practice. In Socrates first we find the required combination of a paramount interest in conduct and an ardent desire for knowledge.

Socrates.—Though Socrates was the first to arrive at a proper conception of the problems of conduct, the general idea did not originate with him. The natural reaction against the metaphysical and ethical dogmatism of the early thinkers had reached its climax in the Sophists (*q.v.*). Gorgias and Protagoras are only representatives of what was really a universal tendency to abandon dogmatic theory and take refuge in practical matters, and especially, as was natural in the Greek city-state, in the civic relations of the citizen. The education given by the Sophists aimed at no general theory of life, but professed to expound the art of getting on in the world and of managing public affairs. In their eulogy of the virtues of the citizen, they pointed out the prudential character of justice and the like as a means of obtaining pleasure and avoiding pain. The Greek conception of society was such that the life of the free-born citizen consisted mainly of his public function, and, therefore, the pseudo-ethical disquisitions of the Sophists satisfied the requirements of the age. None thought of ἀρετή (virtue or excellence) as a unique quality possessed of an intrinsic value, but as the virtue of the citizen, just as good flute-playing was the virtue of the flute-player. We see here, as in other activities of the age, a determination to acquire technical knowledge, and to apply it directly to the practical issue. The Sophists had studied these matters superficially indeed but with thoroughness as far as they went, and it is not remarkable that they should have taken the methods which were successful in rhetoric, and applied them to the "science and art" of civic virtues. Plato's *Protagoras* claims, not unjustly, that in teaching virtue they simply did systematically what every one else was doing at haphazard. But in the true sense of the word, they had no ethical system at all, nor did they contribute save by contrast to ethical speculation. Into this arena of hazy popular common sense Socrates brought a new critical spirit, showing that these popular lecturers, in spite of their fertile eloquence, could not defend their fundamental assumptions, nor even give rational definitions of what they professed to explain. Not only were they thus "ignorant," but they were also inconsistent. Thus, by the aid of his famous "dialectic," Socrates arrived first at the negative result that the professed teachers were as ignorant as he himself claimed to be.

Socrates, first in the history of thought, propounds a positive law of conduct. Virtue is knowledge. This principle involved the paradox that no man, knowing good, would do evil. But it was a

paradox derived from his unanswerable truisms, "Every one wishes for his own good, and would get it if he could," and "No one would deny that justice and virtue generally are goods, and of all goods the best." But this good is not, for Socrates, duty as distinct from interest. The force of the paradox depends upon a blending of duty and interest in the single notion of good. This it is which forms the kernel of the positive thought of Socrates according to Xenophon. He could give no satisfactory account of Good in the abstract, and evaded all questions on this point by saying that he knew "no good that was not good *for something in particular*," but that good is consistent with itself. For himself he prized above all things the wisdom that is virtue, and in the task of producing it he endured the hardest penury, maintaining that such life was richer in enjoyment than a life of luxury.

The historically important characteristics of his moral philosophy, if we take his teaching and character together, may be summarized as follows: (1) an ardent enquiry for knowledge nowhere to be found, but which, if found, would perfect human conduct; (2) a demand meanwhile that men should act as far as possible on some consistent theory; (3) a provisional adhesion to the commonly received view of good, and a perpetual readiness to maintain the harmony of its different elements, and demonstrate the superiority of virtue by an appeal to the standard of self-interest; (4) personal firmness in carrying out consistently such practical convictions as he had attained. It is only when we keep all these points in view that we can understand how from Socratic conversation came all Greek ethical thought.

The Socratic Schools.—Four distinct philosophical schools trace their immediate origin to the circle that gathered round Socrates—the Megarian, the Platonic, the Cynic and the Cyrenaic. The impress of the master is manifest on all, in spite of the wide differences that divide them; they all agree in holding the most important possession of man to be wisdom or knowledge, and the most important knowledge to be knowledge of Good. Here, however, the agreement ends. The more philosophic part of the circle, forming a group in which Euclid of Megara (*see* MEGARIAN SCHOOL) seems at first to have taken the lead, regarded this Good as the object of a still unfulfilled quest, and were led to identify it with the hidden secret of the universe, and thus to pass from ethics to metaphysics. Others again, who were more impressed with the positive and practical side of the master's teaching, made the quest a much simpler affair. They took the Good as already known, and held philosophy to consist in the steady application of this knowledge to conduct. Among these were Antisthenes the Cynic and Aristippus of Cyrene. It is by their recognition of the duty of living consistently by theory instead of mere impulse or custom, their sense of the new value given to life through this rationalization, and their effort to maintain the easy, calm, unwavering firmness of the Socratic temper, that we recognize both Antisthenes and Aristippus as "Socratic men," in spite of the completeness with which they divided their master's positive doctrine into systems diametrically opposed.

Aristippus (*see* CYRENAICS) argued that, if all that is beautiful or admirable in conduct has this quality as being useful, *i.e.*, productive of some further good; this good must be pleasure. Bodily pleasures and pains Aristippus held to be the keenest, though he admitted the existence of purely mental pleasures, such as joy in the prosperity of one's native land. He fully recognized that his good was capable of being realized only in successive parts, and gave even exaggerated emphasis to the rule of seeking the pleasure of the moment, and not troubling oneself about a dubious future. It was in the calm, resolute, skilful culling of such pleasures as circumstances afforded from moment to moment, undisturbed by passion, prejudices or superstition, that he conceived the quality of wisdom to be exhibited. Among the prejudices from which the wise man was free he included all regard to customary morality beyond what was due to the actual penalties attached to its violation; though he held, with Socrates, that these penalties actually render conformity reasonable. Thus early appeared the most thoroughgoing exposition of hedonism.

Far otherwise was the Socratic spirit understood by Antisthenes and the Cynics (*q.v.*). They equally held that no speculative research was needed for the discovery of good and virtue, and maintained that the Socratic wisdom was exhibited, not in the skilful pursuit, but in the rational disregard of pleasure—in the clear apprehension of the intrinsic worthlessness of this and most other objects of men's ordinary desires and aims. Pleasure, indeed, Antisthenes declared evil. He did not overlook the need of supplementing merely intellectual insight by "Socratic force of soul"; but it seemed to him that, by insight and self-mastery combined, an absolute spiritual independence might be attained which left nothing wanting for perfect well-being (*see* DIOGENES). For, regarding poverty, painful toil, disrepute, and such evils as men dread most, these, he argued, were positively useful as means of progress in spiritual freedom and virtue. There is, however, in the Cynic notion of wisdom, no positive criterion beyond the mere negation of irrational desires and prejudices. We saw that Socrates, while not claiming to have found the abstract theory of good or wise conduct, practically understood by it the faithful performance of customary duties. The Cynics more boldly discarded both pleasure and mere custom as alike irrational; but in so doing they left the freed reason with no definite aim but its own freedom. It is absurd, as Plato urged, to say that knowledge is the good, and then when asked "knowledge of what?" to have no positive reply but "of the good"; but the Cynics do not seem to have made any serious effort to escape from this absurdity.

Plato.—The ethics of Plato cannot properly be treated as a finished result, but rather as a continual movement from the position of Socrates towards the more complete, articulate system of Aristotle; except that there are ascetic and mystical suggestions in some parts of Plato's teaching which find no counterpart in Aristotle, and in fact disappear from Greek philosophy soon after Plato's death until they are revived and fantastically developed in Neopythagoreanism and Neoplatonism. The first stage at which we can distinguish Plato's ethical view from that of Socrates is presented in the *Protagoras*, where he makes a serious, though tentative effort to define the object of that knowledge which he with his master regards as the essence of all virtue. Such knowledge, he here maintains, is really mensuration of pleasures and pains, whereby the wise man avoids those mistaken under-estimates of future feelings in comparison with present which we commonly call "yielding to fear or desire." This hedonism has perplexed Plato's readers needlessly, inasmuch as hedonism is the most obvious corollary of the Socratic doctrine that the different common notions of good—the beautiful, the pleasant and the useful—were to be interpreted by each other. By Plato, however, this conclusion could have been held only before he had accomplished the movement of thought by which he carried the Socratic method beyond the range of human conduct and developed it into a metaphysical system.

This movement may be expressed thus. "If we know," said Socrates, "what justice is, we can give an account or definition of it"; true knowledge must be knowledge of the general fact, common to all the individual cases to which we apply our general notion. But this must be no less true of other objects of thought; the same relation of general notions to particular examples extends through the whole physical universe; we can think of it only by means of such notions. True knowledge then must be general knowledge, relating not to individuals primarily, but to the general facts or qualities which individuals exemplify; in fact, our notion of an individual, when examined, is found to be an aggregate of such general qualities. But, again, the object of true knowledge must be what really exists; hence the reality of the universe must lie in general facts or relations.

Plato's philosophy is now concerned with the whole universe of being; yet the ultimate object of his philosophic contemplation is still "the good," now conceived as the ultimate ground of all being and knowledge. How comes this about?

Perhaps we may best explain this by recurring to the original application of the Socratic method to human affairs. Since all rational activity is for some end, the different arts or functions of human industry are naturally defined by a statement of their ends or uses; and similarly, in giving an account of the different artists and functionaries, we necessarily state their end, "what

they are good for." In a society well ordered on Socratic principles, every human being would be put to some use; the essence of his life would consist in doing what he was good for. But again, it is easy to extend this view throughout the whole region of organized life; an eye that does not attain its end by seeing is without the essence of an eye. In short, we may say of all organs and instruments that they are what we think them in proportion as they fulfil their function and attain their end. If, then, we conceive the whole universe organically, as a complex arrangement of means to ends, we shall understand how Plato might hold that all things really *were*, or "realized their idea," in proportion as they accomplished the special end for which they were adapted.

Plato, therefore, took this vast stride of thought, and identified the ultimate notions of ethics and ontology. We have now to see what attitude he will adopt towards the practical enquiries from which he started. What will now be his view of wisdom, virtue, pleasure and their relation to human well-being?

The answer to this question is somewhat complicated. In the first place we have to observe that philosophy has now passed definitely from the market-place into the lecture-room. The quest of Socrates was for the true art of conduct for a man living a practical life among his fellows. But if the objects of abstract thought constitute the real world, of which this world of individual things is but a shadow, it is plain that the highest, most real life must lie in the former region and not in the latter. It is in contemplating the abstract reality which concrete things obscurely exhibit, the type or ideal which they imperfectly imitate, that the true life of the mind in man must consist; and as man is most truly man in proportion as he is mind, the desire of one's own good, which Plato, following Socrates, held to be permanent and essential in every living thing, becomes in its highest form the philosophic yearning for knowledge. This yearning, he held, springs from a sense of want of something formerly possessed, of which there remains a latent memory in the soul, strong in proportion to its philosophic capacity; hence it is that in learning any abstract truth by scientific demonstration we merely bring into clear consciousness hidden memories of a state in which the soul looked upon Reality and Good face to face, before the lapse that imprisoned her in an alien body and mingled her true nature with fleshly feelings and impulses. We thus reach the paradox that the true art of living is really an "art of dying" as far as possible to mere sense, in order more fully to exist in intimate union with absolute goodness and beauty. On the other hand, since the philosopher must still live and act in the concrete sensible world, the Socratic identification of wisdom and virtue is fully maintained by Plato. Only he who apprehends good in the abstract can imitate it in such transient and imperfect good as may be realized in human life; and it is impossible that, having this knowledge, he should not act on it, whether in private or public affairs. Thus, in the true philosopher, we shall necessarily find the practically good man, and also the perfect statesman, if only conditions allow him a sphere for exercising his statesmanship.

The characteristics of this practical goodness in Plato's matured thought correspond to the fundamental conceptions in his view of the universe. The soul of man, in its good or normal condition, must be ordered and harmonized under the guidance of reason. The question then arises, "Wherein does this order or harmony precisely consist?" In explaining how Plato was led to answer this question, it will be well to notice that, while faithfully maintaining the Socratic doctrine that the highest virtue was inseparable from knowledge of the good, he had come to recognize an inferior kind of virtue, possessed by men who were not philosophers. It is plain that if the good that is to be known is the ultimate ground of the whole of things, it is attainable only by a select and carefully trained few. Yet we can hardly restrict all virtue to these alone. What account, then, was to be given of ordinary "civic" bravery, temperance and justice? It seemed clear that men who did their duty, resisting the seductions of fear and desire, must have right opinions, if not knowledge, as to the good and evil in human life; but whence comes this right "opinion"? Partly, Plato said, it comes by the nature and "divine allotment," but for its adequate development "custom and practice" are required. Hence the importance of education and discipline for civic virtue; and even for future philosophers such moral culture, in which physical and aesthetic training must co-operate, is indispensable; no merely intellectual preparation will suffice. His point is that perfect knowledge cannot be implanted in a soul that has not gone through a course of preparation. What, then, is this preparation? A distinct step in psychological analysis was taken when Plato recognized that its effect was to produce the "harmony" above mentioned among different parts of the soul, by subordinating the impulsive elements to reason. These non-rational elements he further distinguished as appetitive and spirited—the practical separateness of which from each other and from reason he held to be established by our inner experience.

On this triple division of the soul he founded a systematic view of the four kinds of goodness recognized by the common moral consciousness of Greece, and in later times known as the Cardinal Virtues (*q.v*). Of these the two most fundamental were wisdom—in its highest form philosophy—and that harmonious and regulated activity of all the elements of the soul which Plato regards as the essence of uprightness in social relations. The import of this term is essentially social; and we can explain Plato's use of it only by reference to the analogy which he drew between the individual man and the community. In a rightly ordered polity social and individual well-being alike would depend on that harmonious action of diverse elements, each performing its proper function, which in its social application is more naturally termed Justice. We see, moreover, how in Plato's view the fundamental virtues, Wisdom and Justice, are mutually involved. Wisdom will necessarily maintain orderly activity, and this latter consists in regulation by wisdom, while the two more special virtues of Courage and Temperance are only different sides or aspects of this wisely regulated action of the complex soul.

Such, then, are the forms in which essential good seemed to manifest itself in human life. It remains to ask whether the statement of these gives a complete account of human well-being, or whether pleasure also is to be included. On this point Plato's view seems to have gone through several oscillations. After apparently maintaining (*Protagoras*) that pleasure is *the* good, he passes first to deny it (*Phaedo, Gorgias*) to be a good at all. This view, however, was too violent a divergence from Socratism for Plato to remain in it. That pleasure is not the real absolute good, was no ground for not including it in the good of concrete human life; and after all only vulgar pleasures were indissolubly linked to the pains of want. Accordingly, in the *Republic* he has no objection to trying the question of the intrinsic superiority of virtuous life by the standard of pleasure, and argues that the good man alone enjoys real pleasure, while the sensualist spends his life in oscillating between painful want and the merely neutral state of painlessness, which he mistakes for positive pleasure. Still more emphatically is it declared in the *Laws* that when we are "discoursing to men, not to gods," we must show that the life which we praise as best and noblest is also that in which there is the greatest excess of pleasure over pain. But though in the *Philebus* a place is allowed to pleasures of colour, form and sound, of intellectual exercise, and even to the "necessary" satisfaction of appetite, it is only a subordinate one. At the same time Plato avoids the exaggeration of denying all positive quality of pleasure even to the coarser sensual gratifications; they are undoubtedly cases of that "replenishment" or "restoration" to its "natural state" of a bodily organ, in which he defines pleasure to consist (see *Timaeus*, pp. 64, 65); he merely maintains that the common estimate of them is to a large extent illusory, or a false appearance of pleasure is produced by contrast with the antecedent or concomitant painful condition of the organ. In the *Philebus*, however, the antithesis of knowledge and pleasure is again sharpened, and a desire to depreciate even good pleasures is more strongly shown; still even here pleasure is recognized as a constituent of that philosophic life which is the highest human good, while in the *Laws*, where the subject is more popularly treated, it is admitted that we cannot convince man the just life is best unless we can also prove it the pleasantest.

Aristotle.—When a student passes from Plato to Aristotle, he is so forcibly impressed by the contrast between the habits of mind of the two authors, and the literary manners of the two philosophers, that it is easy to understand how their systems have come to be popularly conceived as diametrically opposed to each other; and the uncompromising polemic which Aristotle, both in his ethical and in his metaphysical treatises, directs against Plato and the platonists, has tended strongly to confirm this view. Yet a closer inspection shows us that when a later president of the Academy (Antiochus of Ascalon) repudiated the scepticism which for 200 years had been accepted as the traditional Platonic doctrine, he had good grounds for claiming Plato and Aristotle as consentient authorities for the ethical position which he took up. For though Aristotle's divergence from Plato is very conspicuous when we consider either his general conception of the subject of ethics, or the details of his system of virtues, still his agreement with his master is almost complete as regards the main outline of his theory of human good; the difference between the two practically vanishes when we view them in relation to the later controversy between Stoics and Epicureans. Even on the cardinal point on which Aristotle entered into direct controversy with Plato, the definite disagreement between the two is less than at first appears; the objections of the disciple hit that part of the master's system that was rather imagined than thought; the main positive result of Platonic speculation only gains in distinctness by the application of Aristotelian analysis.

The substantial good of the universe, in Aristotle's view, is the pure activity of universal abstract thought, at once subject and object, which, itself changeless and eternal, is the final cause and first source of the whole process of change in the concrete world. And both he and Plato hold that a similar activity of pure speculative intellect is that in which the philosopher will seek to exist, though he must, being a man, concern himself with the affairs of ordinary human life, a region in which his highest good will be attained by realizing perfect moral excellence. Both accept the paradox in the qualified sense that no one can deliberately act contrary to what appears to him good, and that perfect virtue is inseparably bound up with perfect wisdom or moral insight. Both, however, recognize that this actuality of moral insight is not a function of the intellect only, but depends rather on careful training in good habits applied to minds of good natural dispositions, though the doctrine has no doubt a more definite and prominent place in Aristotle's system. The disciple certainly takes a step in advance by stating definitely, as an essential characteristic of virtuous action, that it is chosen for its own sake, for the beauty of virtue alone; but herein he merely formulates the conviction that his master inspires. Nor, finally, does Aristotle's account of the relation of pleasure to human well-being (although he has to combat the extreme anti-hedonism to which the Platonic school under Speusippus had been led) differ materially from the outcome of Plato's thought on this point, as the later dialogues present it to us. Pleasure, in Aristotle's view, is not the primary constituent of well-being, but rather an inseparable accident of it. He no doubt criticizes Plato's account of the nature of pleasure, arguing that we cannot properly conceive pleasure either as a "process" or as "replenishment." But this does not interfere with the general ethical agreement between the two and the doctrine that vicious pleasures are not true or real pleasures is so characteristically Platonic that we are almost surprised to find it in Aristotle.

Aristotle, discarding the transcendentalism of Plato, naturally retained from Plato's teaching the original Socratic method of induction from and verification by common opinion. Indeed, the windings of his exposition are best understood if we consider his literary manner as a kind of Socratic dialogue formalized and reduced to a monologue. He first leads us by an induction to the fundamental notion of ultimate end or good for man. All men, in acting, aim at some result, either for its own sake or as a means to some further end; but obviously not everything can be sought merely as a means; there must be some ultimate end. In fact men commonly recognize such an end, and agree to call it well-being. But they take very different views of its nature; how shall we find the true view? We observe that men are classified according to their functions; all kinds of man, and indeed all organs of man, have their special functions, and are judged as functionaries and organs according as they perform their functions well or ill. May we not then infer that man, as man, has his proper function, and that the well-being or "doing-well" that all seek really lies in fulfilling well the proper function of man—that is, in living well that life of the rational soul which is man's distinctive attribute?

The most important element, then, of well-being or good life for ordinary men Aristotle holds to consist in well-doing as determined by the notions of the different moral excellences. Ethical truth, in his view, is to be attained by careful comparison of particular moral opinions, just as physical truth is to be obtained by induction from particular physical observations. On account of the conflict of opinion in ethics we cannot hope to obtain certainty upon all questions; still reflection will lead us to discard some of the conflicting views and find a reconciliation for others, and will furnish, on the whole, a practically sufficient residuum of moral truth. This adhesion to common sense, though it involves a sacrifice of both depth and completeness in Aristotle's system, gives at the same time an historical interest which renders it deserving of special attention as an analysis of the current Greek ideal of "fair and good life" (καλοκἀγαθία). His virtues are not arranged on any clear philosophic plan; the list shows no serious attempt to consider human life exhaustively, and exhibit the standard of excellence appropriate to its different departments or aspects. He seems to have taken as a starting-point Plato's four cardinal virtues. The two comprehensive notions of Wisdom and Justice (δικαιοσύνη) he treats separately. As regards both, his analysis leads him to diverge considerably from Plato. As we saw, his distinction between practical and speculative Wisdom belongs to the deepest of his disagreement with his master; and in the case of δικαιοσύνη again he distinguishes the wider use of the term to express Law-observance, which (he says) coincides with the social side of virtue generally, and its narrower use for the virtue that "aims at a kind of equality," whether (1) in the distribution of wealth, honour, etc., or (2) in commercial exchange, or (3) in the reparation of wrong done. Then, in arranging the other special virtues, he begins with courage and temperance, which (after Plato) he considers as the excellences of the "irrational element" of the soul. Next follow two pairs of excellences, concerned respectively with wealth and honour: (1) liberality and magnificence, of which the latter is exhibited in greater matters of expenditure, and (2) laudable ambition and highmindedness similarly related to honour. Then comes gentleness—the virtue regulative of anger; and the list is concluded by the excellences of social intercourse, friendliness, truthfulness and decorous wit.

On the whole, there is probably no treatise so masterly as Aristotle's *Ethics*, and containing so much close and valid thought, that yet leaves on the reader's mind so strong an impression of dispersive and incomplete work. It is only by dwelling on these defects that we can understand the small amount of influence that his system exercised during the five centuries after his death, as compared with the effect which it has had, directly or indirectly, in shaping the thought of modern Europe. Partly, no doubt, the limited influence of his disciples, the Peripatetics (*q.v.*), is to be attributed to that exaltation of the purely speculative life which distinguished the Aristotelian ethics from other later systems, and which was too alien from the common moral consciousness to find much acceptance in an age in which the ethical aims of philosophy had again become paramount. Partly, again, the analytical distinctness of Aristotle's manner brings into special prominence the difficulties that attend the Socratic effort to reconcile the ideal aspirations of men with the principles on which their practical reasonings are commonly conducted. The conflict between these two elements of Common Sense was too profound to be compromised; and the moral consciousness of mankind demanded a more trenchant partisanship than Aristotle's. Its demands were met by the Stoic school, which separated the moral from the worldly view of life, with an absoluteness and definiteness that caught the imagination; which regarded practical goodness as the highest manifestation of its ideal of wisdom; and which bound the common notions of duty into an apparently coherent system,

by a formula that comprehended the whole of human life, and exhibited its relation to the ordered process of the universe. The intellectual descent of its ethical doctrines is principally to be traced to Socrates through the Cynics, though an important element in them seems attributable to the school that inherited the "Academy" of Plato. Both Stoic and Cynic maintained, in its sharpest form, the fundamental tenet that the practical knowledge which is virtue, with the condition of soul that is inseparable from it, is alone to be accounted good. The Stoics seem generally to have regarded the eccentricities of Cynicism as an emphatic manner of expressing the essential antithesis between philosophy and the world; and though not necessary or even normal, might be advantageously adopted under certain circumstances.

Stoicism.—Wherein, then, consists this knowledge or wisdom that makes free and perfect? Both Cynics and Stoics (*q.v.*) agreed that the most important part of it was the knowledge that the sole good of man lay in this knowledge or wisdom itself. It must be understood that by wisdom they meant wisdom realized in act; indeed, they did not conceive the existence of wisdom as separable from such realization. We may observe, too, that the Stoics rejected the divergence which we have seen gradually taking place in Platonic-Aristotelian thought from the position of Socrates, "that no one aims at what he knows to be bad." The stress that their psychology laid on the essential unity of the rational self that is the source of voluntary action prevented them from accepting Plato's analysis of the soul into a regulative element and elements needing regulation. They held that what we call passion is a morbid condition of the rational soul, involving erroneous judgment as to what is to be sought or shunned. From such passionate errors the truly wise man will of course be free. He will be conscious indeed of physical appetite; but he will not be misled into supposing that its object is really a good; he cannot, therefore, hope for the attainment of this object or fear to miss it, as these states involve the conception of it as a good. Similarly, though like other men he will be subject to bodily pain, this will not cause him mental grief or disquiet, as his worst agonies will not disturb his clear conviction that it is really indifferent to his true reasonable self.

That this impassive sage was a being not to be found among living men the later Stoics at least were fully aware. They faintly suggested that one or two mortal heroes of old time might have realized the ideal, but they admitted that all other philosophers, even, were merely in a state of progress towards it. This admission did not in the least diminish the rigour of their demand for absolute loyalty to the exclusive claims of wisdom. The assurance of its own unique value that such wisdom involved they held to be an abiding possession for those who had attained it; and without this assurance no act could be truly wise or virtuous. Whatever was not of knowledge was of sin; and the distinction between right and wrong being absolute and not admitting of degrees, all sins were equally sinful; whoever broke the least commandment was guilty of the whole law. Similarly, all wisdom was somehow involved in any one of the manifestations of wisdom, commonly distinguished as particular virtues; though whether these virtues were specifically distinct, or only the same knowledge in different relations, the Stoics do not seem to have agreed.

Aristotle had already been led to attempt a refutation of the Socratic identification of virtue with knowledge; but his attempt had only shown the profound difficulty of attacking the paradox, so long as it was admitted that no one could of deliberate purpose act contrary to what seemed to him best. Now, Aristotle's divergence from Socrates had not led him so far as to deny this; while for the Stoics who had receded to the original Socratic position, the difficulty was still more patent. This theory of virtue led them into two dilemmas. Firstly, if virtue is knowledge, does it follow that vice is involuntary? If not, it must be that ignorance is voluntary. This alternative is the less dangerous to morality, and as such the Stoics chose it. But they were not yet at the end of their perplexities; for while they were thus driven to an extreme extension of the range of human volition, their view of the physical universe involved an equally thorough-going determinism. How could the vicious man be responsible if his vice were strictly predetermined? The Stoics answered that the error which was the essence of vice was so far voluntary that it could be avoided if men chose to exercise their reason. No doubt it depended on the innate force and firmness of a man's soul whether his reason was effectually exercised; but moral responsibility was saved if the vicious act proceeded from the man himself and not from any external cause.

With all this we have not ascertained the positive practical content of this wisdom. How are we to emerge from the barren circle of affirming (1) that wisdom is the sole good and unwisdom the sole evil, and (2) that wisdom is the knowledge of good and evil; and attain some method for determining the particulars of good conduct? The Cynics made no attempt to solve this difficulty; they were content to mean by virtue what any plain man meant by it, except in so far as their sense of independence led them to reject certain received precepts and prejudices. The Stoics, on the other hand, not only worked out a detailed system of duties—or, as they termed them, "things meet and fit" for all occasions of life; they were further especially concerned to comprehend them under a general formula. They found this by bringing out the positive significance of the notion of Nature, which the Cynic had used chiefly in a negative way, as an antithesis to the "conventions" from which his knowledge had made him free. Even in this negative use of the notion it is necessarily implied that whatever active tendencies in man are found to be "natural"—that is, independent of and uncorrupted by social customs and conventions—will properly take effect in outward acts, but the adoption of "conformity to nature" as a general positive rule for outward conduct seems to have been due to the influence on Zeno of Academic teaching. Whence, however, can this authority belong to the natural, unless nature be itself an expression or embodiment of divine law and wisdom? The conception of the world, as organized and filled by divine thought, was common, in some form, to all the philosophies that looked back to Socrates as their founder. This pantheistic doctrine harmonized thoroughly with the Stoic view of human good; but being unable to conceive substance idealistically, they (with considerable aid from the system of Heraclitus) supplied a materialistic side to their pantheism—conceiving divine thought as an attribute of the purest and most primary of material substances, a subtle fiery aether. This theological view of the physical universe had a double effect on the ethics of the Stoic. In the first place it gave to his cardinal conviction of the all-sufficiency of wisdom for human well-being a root of cosmical fact and an atmosphere of religious and social emotion. The exercise of wisdom was now viewed as the pure life of that particle of divine substance which was in very truth the "god within him"; the reason whose supremacy he maintained was the reason of Zeus, and of all gods and reasonable men, no less than his own; it might even be said that he was "as useful to Zeus as Zeus to him." But again, the same conception served to harmonize the higher and the lower elements of human life. For even in the physical or non-rational man, as originally constituted, we may see clear indications of the divine design, which it belongs to his rational will to carry into conscious execution; indeed, in the first stage of human life, before reason is fully developed, uncorrupted natural impulse effects what is afterwards the work of reason. Thus the formula of "living according to nature," in its application to man as the "rational animal," may be understood both as directing that reason is to govern and as indicating how that government is to be practically exercised. In man, as in every other animal, from the moment of birth natural impulse prompts to the maintenance of his physical frame; then, when reason has been developed and has recognized itself as its own sole good, these "primary ends of nature" and whatever promotes these still constitute the outward objects at which reason is to aim; there is a certain value in them, in proportion to which they are "preferred" (προηγμένα) and their opposites "rejected"; indeed it is only in the due and consistent exercise of such choice that wisdom can find its practical manifestation. In this way all or most of the things commonly judged to be "goods"—health, strength, wealth, fame, etc.—are brought within the sphere of the sage's choice, though his real good is solely in the wisdom of the

choice, and not in the thing chosen.

The doctrine of conformity to Nature as the rule of conduct was not peculiar to Stoicism. It is found in the theories of Speusippus, Xenocrates and also to some extent in those of the Peripatetics. The peculiarity of the Stoics lay in their refusing to use the terms "good and evil" in connection with "things indifferent," and in pointing out that philosophers, though independent of these things, must yet deal with them in practical life.

So far we have considered the "nature" of the individual man as apart from his social relations; but the sphere of virtue, as commonly conceived, lies chiefly in these, and this was fully recognized in the Stoic account of duties; indeed, in their exposition of the "natural" basis of justice, the evidence that man was born not for himself but for mankind is the most important part of their work in the region of practical morality. Here, however, we especially notice the double significance of "natural," as applied to (1) what actually exists everywhere or for the most part, and (2) what would exist if the original plan of man's life were fully carried out; and we find that the Stoics have not clearly harmonized the two elements of the notion. That man was "naturally" a social animal Aristotle had already taught; that all rational beings, in the unity of the reason that is common to all, form naturally one community with a common law was (as we saw) an immediate inference from the Stoic conception of the universe as a whole. That the members of this "city of Zeus" should observe their contracts, abstain from mutual harm, combine to protect each other from injury, were obvious points of natural law; while again, it was clearly necessary to the preservation of human society that its members should form sexual unions, produce children and bestow care on their rearing and training. But beyond this nature did not seem to go in determining the relations of the sexes; accordingly, we find that community of wives was a feature of Zeno's ideal commonwealth, just as it was of Plato's; while, again, the strict theory of the school recognized no government or laws as true or binding except those of the sage; he alone is the true ruler, the true king. So far, the Stoic "nature" seems in danger of being as revolutionary as Rousseau's. Practically, however, this revolutionary aspect of the notion was kept for the most part in the background; the rational law of an ideal community was not distinguished from the positive ordinances and customs of actual society; and the "natural" ties that actually bound each man to family, kinsmen, fatherland, and to unwise humanity generally, supplied the outline on which the external manifestation of justice was delineated. It was a fundamental maxim that the sage was to take part in public life; and it does not appear that his political action was to be regulated by any other principles than those commonly accepted in his community. Similarly, in the view taken by the Stoics of the duties of social decorum, and in their attitude to the popular religion, we find a fluctuating compromise between the disposition to repudiate what is conventional, and the disposition to revere what is established, each tendency expressing the principle of "conforming to nature."

Epicureanism.—Among the primary ends of nature, in which wisdom recognized a certain preferability, the Stoics included freedom from bodily pain; but they refused, even in this outer court of wisdom, to find a place for pleasure. They held that the latter was not an object of uncorrupted natural impulse, but an "aftergrowth." They thus endeavoured to resist Epicureanism even on the ground where the latter seems *primâ facie* strongest; in its appeal, namely, to the natural pleasure-seeking of all living things. Nor did they merely mean by pleasure the gratification of bodily appetite; we find, *e.g.*, Chrysippus urging, as a decisive argument against Aristotle, that pure speculation was "a kind of amusement; that is, pleasure." Even the "joy and gladness" that accompany the exercise of virtue seem to have been regarded by them as merely an inseparable accident, not the essential constituent of well-being. It is only by a later modification of Stoicism that cheerfulness or peace of mind is taken as the real ultimate end, to which the exercise of virtue is merely a means. At the same time it is probable that the serene joys of virtue and the griefiessness which the sage was conceived to maintain amid the worst tortures, formed the main attractions of Stoicism for ordinary minds. In this sense it may be fairly said that Stoics and Epicureans made rival offers to mankind of the same kind of happiness; and the philosophical peculiarities of either system may be traced to the desire of being undisturbed by the changes and chances of life. The Stoic claims on this head were the loftiest; as the well-being of their sage was independent, not only of external things and bodily conditions, but of time itself; it was fully realized in a single exercise of wisdom and could not be increased by duration. This paradox is violent, but it is quite in harmony with the spirit of Stoicism; and we are more startled to find that the Epicurean sage, no less than the Stoic, is to be happy even on the rack; that his happiness, too, is unimpaired by being restricted in duration, when his mind has apprehended the natural limits of life; that, in short, Epicurus makes no less strenuous efforts than Zeno to eliminate imperfection from the conditions of human existence. This characteristic, however, is the key to the chief differences between Epicureanism and the more naïve hedonism of Aristippus. The latter system gave the simplest and most obvious answer to the enquiry after ultimate good for man; but besides being liable, when developed consistently, to offend the common moral consciousness, it conspicuously failed to provide the "completeness" and "security" which, as Aristotle says, "one divines to belong to man's true Good." Philosophy, in the Greek view, should be the art as well as the science of good life; and hedonistic philosophy would seem a bungling and uncertain art of pleasure. Hence later thinkers of the Cyrenaic school felt themselves compelled to change their fundamental notion; thus Theodorus defined the good as "gladness" depending on wisdom, as distinct from mere pleasure, while Hegesias proclaimed that happiness was unattainable, and that the chief function of wisdom was to render life painless by producing indifference to all things that give pleasure. But by such changes their system lost the support that it had had in the pleasure-seeking tendencies of ordinary men. It was clear that if philosophic hedonism was to be established on a broad and firm basis, it must in its notion of good combine what the plain man naturally sought with what philosophy could plausibly offer. Such a combination was effected, with some little violence, by Epicurus, whose system with all its defects showed a remarkable power of standing the test of time, as it attracted the unqualified adhesion of generation after generation of disciples for a period of some six centuries.

In the fundamental principle of his philosophy Epicurus is not original. Aristippus (*cf.* also Plato in the *Protagoras* and *Eudoxus*) had already maintained that pleasure is the sole ultimate good, and pain the sole evil; that no pleasure is to be rejected except for its painful consequences, and no pain to be chosen except as a means to greater pleasure; that the stringency of all laws and customs depends solely on the legal and social penalties attached to their violation; that, in short, all virtuous conduct and all speculative activity are empty and useless, except as contributing to the pleasantness of the agent's life. And Epicurus assures us that he means by pleasure what plain men mean by it; and that if the gratifications of appetite and sense are discarded, the notion is emptied of significance. The originality of Epicurus lay in his theory that the highest point of pleasure is attained by the mere removal of pain or disturbance, after which pleasure admits of variation only and not of augmentation; that therefore the utmost gratification of which the body is capable may be provided by the simplest means, and that "natural wealth" is no more than any man can earn. When further he teaches that the attainment of happiness depends almost entirely upon insight and right calculation, fortune having very little to do with it; that the pleasures and pains of the mind are far more important than those of the body, owing to the accumulation of feeling caused by memory and anticipation; and that an indispensable condition of mental happiness lies in relieving the mind of all superstitions, which can be effected only by a thorough knowledge of the physical universe —he introduces an ample area for the exercise of the philosophic intellect. So again, in the stress that he lays on the misery which the most secret wrong-doing must necessarily cause from the perpetual fear of discovery, and in his exuberant exultation of the value of disinterested friendship, he shows a sincere, though not

completely successful effort to avoid the offence that consistent egoistic hedonism is apt to give to ordinary human feeling. As regards friendship, Epicurus was a man of peculiarly unexclusive sympathies. The genial fellowship of the philosophic community that he collected in his garden remained a striking feature in the traditions of his school; and certainly the ideal which Stoics and Epicureans equally cherished of a brotherhood of sages was most easily realized on the Epicurean plan of withdrawing from political and dialectical conflict to simple living and serene leisure, in imitation of the gods apart from the fortuitous concourse of the world. No doubt it was rather the practical than the theoretical side of Epicureanism which gave it so strong a hold.

Later Schools.—The two systems that have just been described were those that most prominently attracted the attention of the ancient world, so far as it was directed to ethics, from their almost simultaneous origin to the end of the 2nd century A.D., when Stoicism almost vanishes from our view. But side by side with them the schools of Plato and Aristotle still maintained a continuity of tradition, and a more or less vigorous life; and philosophy, as a recognized element of Graeco-Roman culture, was understood to be divided among these four branches. The internal history, however, of the four schools was very different. We find no development worthy of notice in the Aristotelian ethics (*see* PERIPATETICS). The Epicureans, again, almost deserve to be called a sect rather than a school. On the other hand, the changes in Stoicism are very noteworthy; and it is the more easy to trace them, as the only original writings of this school which we possess are those of the later Roman Stoics. These changes may be attributed partly to the natural inner development of the system, partly to the reaction of the Roman mind on the essentially Greek doctrine which it received—a reaction all the more inevitable from the very affinity between the Stoic sage and the ancient Roman ideal of manliness. It was natural that the earlier Stoics should be chiefly occupied with delineating the inner and outer characteristics of ideal wisdom and virtue, and that the gap between the ideal sage and the actual philosopher, though never ignored, should yet be somewhat overlooked. But when the question, "What is man's good?" had been answered by an exposition of perfect wisdom, the practical question, "How may a man emerge from the folly of the world, and get on the way towards wisdom?" naturally attracted attention; and the preponderance of moral over scientific interest, which was characteristic of the Roman mind, gave this question especial prominence. The sense of the gap between theory and fact gives to the religious element of Stoicism a new force; the soul, conscious of its weakness, leans on the thought of God, and in the philosopher's attitude towards external events, pious resignation preponderates over self-poised indifference; the old self-reliance of the reason, looking down on man's natural life as a mere field for its exercise, makes room for a positive aversion to the flesh as an alien element imprisoning the spirit; the body has come to be a "corpse which the soul sustains" (Epictetus) and life a "sojourn in a strange land" (Marcus Aurelius); in short, the ethical idealism of Zeno has begun to borrow from the metaphysical idealism of Plato.

In no one of these schools was the outward coherence of tradition so much strained by inner changes as it was in Plato's. The alterations, however, in the metaphysical position of the Academics had little effect on their ethical teaching, as, even during the period of Scepticism, they appear to have presented as probable the same general view of human good which Antiochus afterwards dogmatically announced as a revival of the common doctrine of Plato and Aristotle. And during the period of a century and a half between Antiochus and Plutarch, we may suppose the school to have maintained the old controversy with Stoicism on much the same ground, accepting the formula of "life according to nature," but demanding that the "good" of man should refer to his nature as a whole, the good of his rational part being the chief element, and always preferable in case of conflict, but yet not absolutely his sole good. In Plutarch, however, we see the same tendencies of change that we have noticed in later Stoicism. The conception of a normal harmony between the higher and lower elements of human life has begun to be disturbed, and the side of Plato's teaching that deals with the inevitable imperfections of the world of concrete experience becomes again prominent. For example, we find Plutarch amplifying the suggestion in Plato's latest treatise (the *Laws*) that this imperfection is due to a bad world-soul that strives against the good—a suggestion which is alien to the general tenor of Plato's doctrine, and had consequently been unnoticed during the intervening centuries. We observe, again, the value that Plutarch attaches, not merely to the sustainment and consolation of rational religion, but to the supernatural communications vouchsafed by the divinity to certain human beings in dreams, through oracles, or by special warnings, like those of the genius of Socrates. For these flashes of intuition, he holds, the soul should be prepared by tranquil repose and the subjugation of sensuality.

Neo-Platonism.—The system of Plotinus (A.D. 205–270) is a striking development of that element of Platonism which has had most fascination for the mediaeval and even for the modern mind, but which had almost vanished out of sight in the controversies of the post-Aristotelian schools. At the same time the differences are the more noteworthy from the reverent adhesion which the Neoplatonists always maintain to Plato. Plato identified good with the real essence of things; with that in them which is definitely conceivable and knowable. It belongs to this view to regard the imperfection of things as devoid of real being, and so incapable of being definitely thought or known; accordingly, we find that Plato has no technical term for that in the concrete sensible world which hinders it from perfectly expressing the abstract ideal world, and which in Aristotle's system is distinguished as absolutely formless matter (ὕλη). And so, when we pass from the ontology to the ethics of Platonism, we find that, though the highest life is only to be realized by turning away from concrete human affairs and their material environment, still the sensible world is not yet an object of positive moral aversion; it is rather something which the philosopher is seriously concerned to make as harmonious, good and beautiful as possible. But in Neoplatonism the inferiority of the condition in which the embodied human soul finds itself is more intensely and painfully felt; hence an express recognition of formless matter as the "first evil," from which is derived the "second evil," body (σῶμα), to whose influence all the evil in the soul's existence is due. Accordingly the ethics of Plotinus represent, we may say, the moral idealism of the Stoics cut loose from nature. The only good of man is the pure existence of the soul, which in itself, apart from the contagion of the body, is perfectly free from error or defect; if only it can be restored to the untrammeled activity of its original being, nothing external, nothing bodily, can positively impair its perfect welfare. It is only the lowest form of virtue—the "civic" virtue of Plato's *Republic*—that is employed in regulating those animal impulses whose presence in the soul is due to its mixture with the body; higher or philosophic wisdom, temperance, courage and justice are essentially purifications from this contagion; until finally the highest mode of goodness is reached, in which the soul has no community with the body, and is entirely turned towards reason. It should be observed that Plotinus himself is still too Platonic to hold that the absolute mortification of natural bodily appetites is required for purifying the soul; but this ascetic inference was drawn to the fullest extent by his disciple Porphyry.

There is, however, a yet higher point to be reached in the upward ascent of the Neoplatonist from matter; and here the divergence of Plotinus from Platonic idealism is none the less striking, because it is a *bona fide* result of reverent reflection on Plato's teaching. The cardinal assumption of Plato's metaphysic is, that the real is definitely thinkable and knowable in proportion as it is real; so that the farther the mind advances in abstraction from sensible particulars and apprehension of real being, the more definite and clear its thought becomes. Plotinus, however, urges that, as all thought involves difference or duality of some kind, it cannot be the primary fact in the universe, what we call God. He must be an essential unity prior to this duality, a Being wholly without difference or determination; and, accordingly, the highest mode of human existence, in which the soul apprehends this absolute, must be one in which all definite thought is transcended, and all consciousness of self lost in the absorbing ecstacy.

Porphyry tells us that his master Plotinus attained the highest state four times during the six years which he spent with him.

Neoplatonism, originally Alexandrine, is often regarded as Hellenistic rather than Hellenic, a product of the mingling of Greek with Oriental civilization. But however Oriental may have been the cast of mind that welcomed this theosophic asceticism, the forms of thought by which these views were philosophically reached are essentially Greek; and it is by a thoroughly intelligible process of natural development, in which the intensification of the moral consciousness represented by Stoicism plays an important part, that the Hellenic pursuit of knowledge culminates in a preparation for ecstacy, and the Hellenic idealization of man's natural life ends in a settled antipathy to the body and its works. At the same time we ought not to overlook the affinities between the doctrine of Plotinus and that remarkable combination of Greek and Hebrew thought which Philo Judaeus had expounded two centuries before; nor the fact that Neoplatonism was developed in conscious antagonism to the new religion which had spread from Judea, and was already threatening the conquest of the Graeco-Roman world, and also to the Gnostic systems (*see* GNOSTICISM); nor, finally, that it furnished the chief theoretical support in the last desperate struggle under Julian to retain the old worship.

MEDIAEVAL ETHICS

Christianity.—In the present article we are not concerned with the origin of the Christian religion, nor with its outward history. Nor have we to consider the special doctrines that have formed the bond of union of the Christian communities except in their ethical aspect, their bearing on the systematization of human aims and activities. This aspect, however, must necessarily be prominent in discussing Christianity, which cannot be adequately treated merely as a system of theological beliefs divinely revealed, and special observances divinely sanctioned; for it claims to regulate the whole man, in all departments of his existence. It was not till the 4th century A.D. that the first attempt was made to offer a systematic exposition of Christian morality; and nine centuries more had passed away before a genuinely philosophic intellect, trained by a full study of Aristotle, undertook to give complete scientific form to the ethical doctrine of the Catholic Church. Before, however, we take a brief survey of the progress of systematic ethics from Ambrose to Thomas Aquinas, it may be well to examine the chief features of the new moral consciousness that had spread through Graeco-Roman civilization, and was awaiting philosophic synthesis. It will be convenient to consider first the new *form* or universal characteristics of Christian morality, and afterwards to note the chief points in the *matter* or particulars of virtue which received development from the new religion.

The first point to be noticed is the new conception of morality as the positive law of a theocratic community possessing a written code imposed by divine revelation, and sanctioned by divine promises and threatenings. It is true that we find in ancient thought, from Socrates downwards, the notion of a law of God, eternal and immutable, partly expressed and partly obscured by the shifting codes and customs of actual human societies. But the sanctions of this law were vaguely and, for the most part, feebly imagined; its principles were essentially unwritten, and thus referred not to the external will of an Almighty Being who claimed unquestioning submission, but rather to the reason that gods and men shared, by the exercise of which alone they could be adequately known and defined. Hence, even if the notion of law had been more prominent than it was in ancient ethical thought, it could never have led to a juridical, as distinct from a philosophical, treatment of morality. In Christianity, on the other hand, we early find that the method of moralists determining right conduct is to a great extent analogous to that of jurisconsults interpreting a code. It is asssumed that divine commands have been implicitly given for all occasions of life, and that they are to be ascertained in particular cases by interpretation of the general rules obtained from texts of scripture, and by inference from scriptural examples. This juridical method descended naturally from the Jewish theocracy, of which Christendom was a universalization. Moral insight, in the view of the most thoughtful Jews of the age immediately preceding Christianity, was conceived as knowledge of a divine code, emanating from an authority external to human reason which had only the function of interpreting and applying its rules. This law was derived partly from Moses, partly from the utterances of the later prophets, partly from oral tradition and from the commentaries and supplementary maxims of generations of students. Christianity inherited the notion of a written divine code acknowledged as such by the "true Israel"—now potentially including the whole of mankind, or at least the chosen of all nations—on the sincere acceptance of which the Christian's share of the divine promises to Israel depended. And though the ceremonial part of the old Hebrew code was altogether rejected, and with it all the supplementary jurisprudence resting on tradition and erudite commentary, still God's law was believed to be contained in the sacred books of the Jews, supplemented by the teaching of Christ and his apostles. By the recognition of this law the Church was constituted as an ordered community, essentially distinct from the State; the distinction between the two was emphasized by the withdrawal of the early Christians from civic life, to avoid the performance of idolatrous ceremonies imposed as official expressions of loyalty, and by the persecutions which they had to endure, when the spread of an association apparently so hostile to the framework of ancient society had at length alarmed the imperial Government. Nor was the distinction obliterated by the recognition of Christianity as the State religion under Constantine.

Thus the jural form in which morality was conceived only emphasized the fundamental difference between it and the laws of the State. The ultimate sanctions of the moral code were the infinite rewards and punishments awaiting the immortal soul hereafter; but the Church early felt the necessity of withdrawing the privileges of membership from apostates and allowing them to be gradually regained only by a solemn ceremonial expressive of repentance, protracted through several years. This formal and regulated "penitence" was extended from apostasy to other grave—or, as they were subsequently called, "deadly"—sins; while for minor offences all Christians were called upon to express contrition by fasting and abstinence from ordinarily permitted pleasures, as well as verbally in public and private devotions. "Excommunication" and "penance" thus came to be temporal ecclesiastical sanctions of the moral law. As the graduation of these sanctions naturally became more minute, a correspondingly detailed classification of offences was rendered necessary, and thus a system of ecclesiastical jurisprudence was gradually produced, somewhat analogous to that of Judaism. At the same time this tendency to make prominent a scheme of external duties has always been counteracted in Christianity by the remembrance of its original antithesis to Jewish legalism. We find that this antithesis, as exaggerated by some of the Gnostic sects of the 2nd and 3rd centuries A.D., led, not merely to theoretical antinomianism, but even (if the charges of their orthodox opponents are not entirely to be discredited) to gross immorality of conduct. A similar tendency has shown itself at other periods of Church history. And though such antinomianism has always been sternly repudiated by the moral consciousness of Christendom, it has never been forgotten that "inwardness," rightness of heart or spirit, is the preeminent characteristic of Christian goodness. It must not, of course, be supposed that the need of something more than mere fulfilment of external duty was ignored even by the later Judaism. Rabbinic erudition could not forget the repression of vicious desires in the tenth commandment, the stress laid in Deuteronomy on the necessity of service to God, or the inculcation by later prophets of humility and faith. "The real and only Pharisee," says the Talmud, "is he who does the will of his Father because he loves Him." But it remains true that the contrast with the "righteousness of the scribes and pharisees" has always served to mark the requirement of "inwardness" as a distinctive feature of the Christian code—an inwardness not merely negative, tending to the repression of vicious desires as well as vicious acts, but also involving a positive rectitude of the inner state of the soul.

In this aspect Christianity invites comparison with Stoicism, and indeed with pagan ethical philosophy generally, if we except the hedonistic schools. Rightness of purpose, preference of virtue

for its own sake, suppression of vicious desires, were made essential points by the Aristotelians, who attached the most importance to outward circumstances in their view of virtue, no less than by the Stoics, to whom all outward things were indifferent. The fundamental differences between pagan and Christian ethics depend not on any difference in the value set on rightness of heart, but on different views of the essential form or conditions of this inward rightness. In neither case is it presented purely and simply as moral rectitude. By the pagan philosophers it was always conceived under the form of Knowledge or Wisdom, it being inconceivable to all the schools sprung from Socrates that a man could truly know his own good and yet deliberately choose anything else. This knowledge, as Aristotle held, might be permanently precluded by vicious habits, or temporarily obliterated by passion, but if present in the mind it must produce rightness of purpose. Or even if it were held with some of the Stoics that true wisdom was out of the reach of the best men actually living, it none the less remained the ideal condition of perfect human life. By Christian teachers, on the other hand, the inner springs of good conduct were generally conceived as Faith and Love. Of these notions the former has a somewhat complex ethical import; it seems to blend several elements differently prominent in different minds. Its simplest and commonest meaning is that emphasized in the contrast of "faith" with "sight"; where it signifies belief in the invisible divine order represented by the Church, in the actuality of the law, the threats, the promises of God, in spite of all the influences in man's natural life that tend to obscure this belief. Out of this contrast there ultimately grew an essentially different opposition between faith and knowledge or reason, according to which the theological basis of ethics was contrasted with the philosophical; the theologians maintaining sometimes that the divine law is essentially arbitrary, the expression of will, not reason; more frequently that its reasonableness is inscrutable, and that actual human reason should confine itself to examining the credentials of God's messengers, and not the message itself. But in early Christianity this latter antithesis was as yet undeveloped; faith means simply force in clinging to moral and religious conviction, whatever their rational grounds may be; this force, in the Christian consciousness, being inseparably bound up with personal loyalty and trust towards Christ, the leader in the battle with evil, the ruler of the kingdom to be realized. So far, however, there is no ethical difference between Christian faith and that of Judaism, or its later imitation, Mohammedanism.

A more distinctively Christian, and a more deeply moral significance is given to the notion in the antithesis of "faith" and "works." Here faith means more than loyal acceptance of the divine law and reverent trust in the lawgiver; it implies a consciousness, at once continually present and continually transcended, of the radical imperfection of all human obedience to the law, and at the same time of the irremissible condemnation which this imperfection entails. The Stoic doctrine of the worthlessness of ordinary human virtue, and the stern paradox that all offenders are equally, in so far as all are absolutely, guilty, find their counterparts in Christianity; but the latter overcomes its practical exclusiveness through faith. This faith, again, may be conceived in two modes, essentially distinct though usually combined. In one view it gives the believer strength to attain, by God's supernatural aid or "grace," a goodness of which he is naturally incapable; in the other view it gives him an assurance that, though he knows himself a sinner deserving of utter condemnation, a perfectly just God still regards him with favour on account of the perfect services and suffering of Christ.

But faith is rather an indispensable pre-requisite than the essential motive principle of Christian good conduct. This motive is supplied by the other central notion, love. On love depends the "fulfilling of the law," and the sole moral value of Christian duty —that is, on love to God, in the first place, which in its fullest development must spring from Christian faith; and, secondly, love to all mankind, as the objects of divine love and sharers in the humanity ennobled by the incarnation. This derivative philanthropy characterizes the spirit in which all Christian performance of social duty is to be done; loving devotion to God being the fundamental attitude of mind that is to be maintained throughout the whole of the Christian's life. But further, as regards abstinence from unlawful acts and desires prompting to them, we have to notice another form in which the inwardness of Christian morality manifests itself. The profound horror with which the Christian's conception of a suffering as well as an avenging divinity tended to make him regard all condemnable acts was tinged with a sentiment which we may describe as a ceremonial aversion moralized—the aversion, that is, to impurity. In Judaism, as in other, especially Oriental, religions, the natural dislike of material defilement has been elevated into a religious sentiment, and made to support a complicated system of quasi-sanitary abstinences and ceremonial purifications; then, as the ethical element predominated in the Jewish religion, a moral symbolism was felt to reside in the ceremonial code, and thus aversion to impurity came to be a common form of the ethico-religious sentiment. Then, when Christianity threw off the Mosaic ritual, this religious sense of purity was left with no other sphere besides morality; while, from its highly idealized character, it was peculiarly well adapted for that repression of vicious desires which Christianity claimed as its special function.

The distinctive features of Christian ethics are obedience, unworldliness, benevolence, purity and humility. They are naturally connected with the more general characteristics just stated; though many of them may also be referred directly to the example and precepts of Christ, and in several cases they are clearly due to both causes, inseparably combined.

1. We may notice, in the first place, that the conception of morality as a code which, if not in itself arbitrary, is yet to be accepted by men with unquestioning submission, tends naturally to bring into prominence the virtue of *obedience to authority*; just as the philosophic view of goodness as the realization of reason gives a special value to *self-determination* and independence.

2. Again, the opposition between the natural world and the spiritual order into which the Christian has been born anew led not merely to a contempt equal to that of the Stoic for wealth, fame, power and other objects of worldly pursuit, but also, for some time at least, to a comparative depreciation of the domestic and civic relations of the natural man. This tendency was exhibited most simply and generally in the earliest period of the Church's history. In the view of primitive Christians, ordinary human society was a world temporarily surrendered to Satanic rule, over which a swift and sudden destruction was impending; in such a world the little band who were gathered in the ark of the Church could have no part or lot. On the other hand, it was difficult practically to realize this alienation, and a keen sense of this difficulty induced the same hostility to the body as a hindrance, that we find to some extent in Plato, but more fully developed in Neoplatonism, Neopythagoreanism, and other products of the mingling of Greek with Oriental thought. This feeling is exhibited in the value set on fasting in the Christian Church from the earliest times, and in an extreme form in the self-torments of later monasticism; while both tendencies, anti-worldliness and anti-sensualism, seem to have combined in causing the preference of celibacy over marriage. Patriotism, again, and the sense of civic duty, the most elevated of all social sentiments in the Graeco-Roman civilization, tended, under Christianity, either to expand itself into universal philanthropy or to concentrate itself on the ecclesiastical community. We might further derive from the general spirit of Christian unworldliness that repudiation of the secular modes of conflict, even in a righteous cause, which substituted a passive patience and endurance for the old pagan virtue of courage. Here, however, we clearly trace the influence of Christ's express prohibition of violent resistance to violence, and his inculcation, by example and precept, of a love that was to conquer even natural resentment. An extreme result of this influence is shown in Tertullian's view, that no Christian could properly hold the office of a secular magistrate in which he would have to doom to death, chains, imprisonment; but even more sober writers, such as Ambrose, extend Christian passivity so far as to preclude self-defence even against a murderous assault. The common sense of Christendom gradually shook off these extravagances; but the reluctance

to shed blood lingered long, and was hardly extinguished even by the growing horror of heresy. We have a curious relic of this in later times when the heretic was doomed to the stake that he might be punished in some manner "short of bloodshed."

3. It is, however, in the impulse given to practical beneficence in all its forms, by the exaltation of love as the root of all virtues, that the most important influence of Christianity on the particulars of civilized morality is to be found; although the exact amount of this influence is here somewhat difficult to ascertain, since it merely carries farther a development traceable in the history of pagan morality. This development appears when we compare the different post-Socratic systems of ethics. In Plato's exposition of the different virtues there is no mention whatever of benevolence, although his writings show a keen sense of the importance of friendship as an element of philosophic life, especially of the intense personal affection naturally arising between master and disciple. Aristotle goes somewhat further in recognizing the moral value of friendship; and though he considers that in its highest form it can be realized only by the fellowship of the wise and good, he yet extends the notion so as to include the domestic affections, and takes notice of the importance of mutual kindness in binding together all human societies. Still in his formal statement of the different virtues, positive beneficence is discernible only under the notion of "liberality." Cicero, on the other hand, in his paraphrase of a Stoic treatise on external duties (*De officiis*), ranks the rendering of positive services to other men as a chief department of social duty; and the Stoics generally recognized the universal fellowship and natural mutual claims of human beings as such. Indeed, this recognition in later Stoicism is sometimes expressed with so much warmth of feeling as to be hardly distinguishable from Christian philanthropy. Nor was this regard for humanity merely a doctrine of the school. Partly through the influence of Stoic and other Greek philosophy, partly from the natural expansion of human sympathies, the legislation of the empire, during the first three centuries, shows a steady development in the direction of natural justice and humanity; and some similar progress may be traced in the general tone of moral opinion. Still the utmost point that this development reached fell considerably short of the standard of Christian charity. Without dwelling on the immense impetus given to the practice of social duty generally by the religion that made beneficence a form of divine service, and identified "piety" with "pity," we have to put down as definite changes introduced by Christianity—(1) the severe condemnation and final suppression of the practice of exposing infants; (2) effective abhorrence of the barbarism of gladiatorial combats; (3) immediate moral mitigation of slavery, and a strong encouragement of emancipation; (4) great extension of the eleemosynary provision made for the sick and the poor. As regards almsgiving, however—the importance of which has caused it to usurp, in modern languages, the general name of "charity"—it ought to be observed that Christianity merely universalized a duty always inculcated by Judaism.

4. The same may be said of the stricter regulation which Christianity enforced on the relations of the sexes; except so far as the prohibition of divorce is concerned, and the stress laid on "purity of heart" as contrasted with merely outward chastity.

5. Even the peculiarly Christian virtue of humility, which presents so striking a contrast to the Greek "highmindedness," was anticipated in the Rabbinic teaching. Its far greater prominence under the new dispensation may be partly referred to the express teaching and example of Christ; partly, in so far as the virtue is manifested in the renunciation of external rank and dignity, or the glory of merely secular gifts and acquirements, it is one aspect of the unworldliness which we have already noticed; while the deeper humility that represses the claim of personal merit even in the saint belongs to the strict self-examination, the continual sense of imperfection, the utter reliance on strength not his own, which characterize the inner moral life of the Christian.

We have, however, yet to notice the enlargement of the sphere of ethics due to its close connection with theology; for while this added religious force and sanction to ordinary moral obligations, it equally tended to impart a moral aspect to religious belief and worship. "Duty to God" had not been altogether unrecognized by pagan moralists; but the rather dubious relations of even the more orthodox philosophy to the established polytheism had generally prevented them from laying much stress upon it. Again the emphasis laid on inwardness in Christian ethics caused orthodoxy or correctness of religious belief to be regarded as essential to goodness, and heresy as the most fatal of vices, corrupting as it did the very springs of Christian life. To the philosophers (with the single exception of Plato), however, convinced as they were that the multitude must necessarily miss true well-being through their folly and ignorance, it could never occur to guard against these evils by any other method than that of providing philosophic instruction for the few; whereas the Christian clergy, whose function it was to offer truth and eternal life to all mankind, naturally regarded theological misbelief as insidious preventible contagion. Indeed, their sense of its deadliness was so keen that, when they were at length able to control the secular administration, they rapidly overcame their aversion to bloodshed, and initiated that long series of religious persecutions to which we find no parallel in the pre-Christian civilization of Europe.

Lastly, we must observe that, in proportion as the legal conception of morality as a code of which the violation deserves supernatural punishment predominated over the philosophic view of ethics as the method for attaining natural felicity, the question of man's freedom of will to obey the law necessarily became prominent. At the same time it cannot be broadly said that Christianity took a decisive side in the metaphysical controversy on free-will and necessity; since, just as in Greek philosophy the need of maintaining freedom as the ground of responsibility clashes with the conviction that no one deliberately chooses his own harm, so in Christian ethics it clashes with the attribution of all true human virtue to supernatural grace, as well as with the belief in divine foreknowledge. All we can say is that in the development of Christian thought the conflict of conceptions was far more profoundly felt, and far more serious efforts were made to evade or transcend it.

In the preceding account of Christian morality, it has been already indicated that the characteristics delineated did not all exhibit themselves simultaneously to the same extent, or with perfect uniformity throughout the Church. Changes in the external condition of Christianity, the different degrees of civilization in the societies of which it was the dominant religion, and the natural process of internal development, continually brought different features into prominence; while again, the important antagonisms of opinion within Christendom frequently involved ethical issues —even in the Eastern Church—until in the 4th century it began to be absorbed in the labour of a dogmatic construction. Thus, for example, the anti-secular tendencies of the new creed, to which Tertullian (160–220) gave violent and rigid expression, were exaggerated in the Montanist heresy which he ultimately joined; on the other hand, Clement of Alexandria, in opposition to the general tone of his age, maintained the value of pagan philosophy for the development of Christian faith into true knowledge (Gnosis), and the value of the natural development of man through marriage for the normal perfecting of the Christian life. So again, there is a marked difference between the writers before Augustine and those that succeeded him in all that concerns the internal conditions of Christian morality. By Justin and other apologists the need of redemption, faith, grace is indeed recognized, but the theological system depending on these notions is not sufficiently developed to come into even apparent antagonism with the freedom of the will. Christianity is for the most part conceived as essentially a proclamation through the Divine Word, to immortal beings gifted with free choice, of the true code of conduct sanctioned by eternal rewards and punishments. This legalism contrasts strikingly with the efforts of pagan philosophy to exhibit virtue as its own reward; and the contrast is triumphantly pointed out by more than one early Christian writer. It is plain, however, that on this view it was impossible to maintain a difference in kind between Christian and pagan morality; the philosopher's conformity to the rules of chastity and beneficence was indistinguishable from the saint's. But when this

inference was developed in the teaching of Pelagius, it was repudiated as heretical by the Church, under the powerful leadership of Augustine (354–430); and the doctrine of man's incapacity to obey God's law by his unaided moral energy was pressed to a point at which it was difficult to reconcile it with the freedom of the will. Augustine attempted to Christianize the Platonic list of virtues. This was probably due to the influence of his master, Ambrose, in whose *De officiis ministrarum* is found the first attempt to systematize Christian duties on a Platonic plan.

Under the influence of Ambrose and Augustine, the four cardinal virtues furnished a basis on which the systematic ethical theories of subsequent theologians were built. With them the triad of Christian graces, Faith, Hope and Love, and the seven gifts of the Spirit (Isa. xi. 2) were often combined. In antithesis to this list, an enumeration of the "deadly sins" obtained currency. These were at first commonly reckoned as eight; but a preference for mystical numbers characteristic of mediaeval theologians finally reduced them to seven. The statement of them is variously given—Pride, Avarice, Anger, Gluttony, Unchastity, are found in all the lists; the remaining two (or three) are variously selected from among Envy, Vainglory, and the rather singular sins Gloominess (*tristitia*) and Languid Indifference (*acidia* or *acedia*, from Gr. ἀκηδία). These latter notions show plainly, what indeed might be inferred from a study of the list as a whole, that it represents the moral experience of the monastic life, which for some centuries was more and more unquestioningly regarded as in a peculiar sense "religious." It should be observed that the (also Augustinian) distinction between "deadly" and "venial" sins had a technical reference to the quasi-jural administration of ecclesiastical discipline, which grew gradually more organized as the spiritual power of the Church established itself amid the ruins of the Western empire, and slowly developed into the theocracy that almost dominated Europe during the latter part of the middle ages. "Deadly" sins were those for which formal ecclesiastical penance was held to be necessary, in order to save the sinner from eternal damnation; for "venial" sins he might obtain forgiveness, through prayer, almsgiving and the observance of the regular fasts. This ecclesiastical jurisprudence, and indeed the general relation of the church to the ruder races with which it had to deal, necessarily tended to encourage a somewhat external view of morality.

Aquinas.—Scholastic ethics, like scholastic philosophy, attained its completest result in the teaching of Thomas Aquinas, whose moral philosophy is Aristotelianism with a Neoplatonic tinge, supplemented by a view of Christian dogma derived from Augustine. All action or movement of all things irrational as well as rational is directed towards some end or good—that is, really and ultimately towards God himself, the ground and first cause of all being, and unmoved principle of all movement. This universal though unconscious striving after God, since he is essentially intelligible, exhibits itself in its highest form in rational beings as a desire for knowledge of him; such knowledge, however, is beyond all ordinary exercise of reason, and may be only partially revealed to man here below. Thus the *summum bonum* for man is objectively God, subjectively the happiness to be derived from loving vision of His perfections; although there is a lower kind of happiness to be realized here below in a normal human existence of virtue and friendship, with mind and body sound and whole and properly trained for the needs of life. The higher happiness is given to man by free grace of God; but it is given to those only whose heart is right, and as a reward of virtuous actions. In his *Summa theologiae* Aquinas gave a detailed account of particular duties. This was frequently drawn upon when the quasi-legal treatment of morality came again into prominence as the philosophic interest of Scholasticism faded in the 14th and 15th centuries. One result of this movement was the development of casuistry (*q.v.*).

Humanism.—In the 17th century, however, the interest of this quasi-legal treatment of morality gradually faded; and the ethical studies of educated minds were occupied with the attempt, renewed after so many centuries, to find an independent philosophical basis for the moral code. The renewal of this attempt was only indirectly due to the Reformation; it is rather to be connected with the more extreme reaction from the mediaeval religion which was partly caused by, partly expressed in, that enthusiastic study of the remains of old pagan culture that spread from Italy over Europe in the 15th and 16th centuries. To this "humanism" the Reformation seemed at first more hostile than the Roman hierarchy; indeed, the extent to which this latter had allowed itself to become paganized by the Renaissance was one of the points that especially roused the Reformers' indignation. Not the less important is the indirect stimulus given by the Reformation towards the development of a moral philosophy independent alike of Catholic and Protestant assumptions. Scholasticism, while reviving philosophy as a handmaid to theology, had metamorphosed its method into one resembling that of its mistress; thus shackling the renascent intellectual activity which it stimulated by the double bondage to Aristotle and to the Church. When the Reformation shook the traditional authority in one department, the blow was necessarily felt in the other. Not 20 years after Luther's defiance of the pope, the startling thesis "that all that Aristotle taught was false" was prosperously maintained by the youthful Ramus before the university of Paris; and almost contemporaneously the group of remarkable thinkers in Italy who heralded the dawn of modern physical science—Cardanus, Telesio, Patrizzi, Campanella, Bruno—began to propound their Aristotelian theories of the constitution of the physical universe. It was to be foreseen that a similar assertion of independence would make itself heard in ethics also; and, indeed, amid the clash of dogmatic convictions, and the variations of private judgment, it was natural to seek for an ethical method that might claim universal acceptance from all sects.

MODERN ETHICS

Hugo Grotius.—The need of such independent principles was most strongly felt in the region of man's civil and political relations, especially the mutual relations of communities. Accordingly we find that modern ethical controversy began in a discussion of the law of nature. Albericus Gentilis (1557–1611) and Hugo Grotius (1583–1645) were the first to give a systematic account. Natural law, according to Grotius and other writers of the age, is that part of divine law which follows from the essential nature of man, who is distinguished from animals by his "appetite" for tranquil association with his fellows, and his tendency to act on general principles. It is therefore as unalterable, even by God himself, as the truths of mathematics, although its effect may be overruled in any particular case by an express command of God; hence it is cognizable *a priori*, from the abstract consideration of human nature, though its existence may be known *a posteriori* also from its universal acceptance in human societies. The conception, as we have seen, was taken from the later Roman jurists; by them, however, the law of nature was conceived as something that underlay existing law, and was to be looked for through it, though it might ultimately supersede it, and in the meanwhile represented an ideal standard, by which improvements in legislation were to be guided. Still the language of the jurists in some passages (cf. *Inst. of Justinian*, ii. 1, 2) clearly implied a period of human history in which men were governed by natural law alone, prior to the institution of civil society. Thus there had become current the conception of a "state of nature" in which individuals or single families lived side by side—under none other than those "natural" laws which prohibited mutual injury and interference in the free use of the goods of the earth common to all, and upheld parental authority, fidelity of wives, and the observance of compacts freely made. This conception Grotius took, and gave it additional force and solidity by using the principles of this natural law for the determination of international rights and duties, it being obvious that independent nations, in their corporate capacities, were still in that "state of nature" in their mutual relations. It was not, of course, assumed that these laws were universally obeyed; indeed, one point with which Grotius is especially concerned is the natural right of private war, arising out of the violation of more primary rights. Still a general observance was involved in the idea of a natural law as a "dictate

of right reason indicating the agreement or disagreement of an act with man's rational and social nature"; and we may observe that it was especially necessary to assume such a general observance in the case of contracts, since it was by an "express or tacit pact" that the right of property (as distinct from the mere right to non-interference during use) was held by him to have been instituted. A similar "fundamental pact" had long been generally regarded as the normal origin of legitimate sovereignty.

The ideas above expressed were not peculiar to Grotius; in particular the doctrine of the "fundamental pact" as the jural basis of government had long been maintained, especially in England, where the constitution historically established readily suggested such a compact. At the same time the rapid and remarkable success of Grotius's treatise (*De jure belli et pacis*) brought his view of Natural Right into prominence, and suggested such questions as—"What is man's ultimate reason for obeying these laws? Wherein exactly does this their agreement with his rational and social nature consist? How far, and in what sense, is his nature really social?"

English Ethics: Hobbes.—It was the answer which Hobbes (1588–1679) gave to these fundamental questions that supplied the starting-point for independent ethical philosophy in England. The nature of this answer was determined by the psychological views to which Hobbes had been led, possibly to some extent under the influence of Bacon, partly perhaps through association with his younger contemporary Gassendi, who, in two treatises, published between the appearance of Hobbes's *De cive* (1642) and that of the *Leviathan* (1651), endeavoured to revive interest in Epicurus. Hobbes's psychology is in the first place materialistic; he holds, that is, that in any of the psychophysical phenomena of human nature the reality is a material process of which the mental feeling is a mere "appearance." Accordingly he regards pleasure as essentially motion "helping vital action," and pain as motion "hindering" it. There is no logical connection between this theory and the doctrine that appetite or desire has always pleasure (or the absence of pain) for its object; but a materialist, framing a system of psychology, will naturally direct his attention to the impulses arising out of bodily wants, whose obvious end is the preservation of the agent's organism; and this, together with a philosophic wish to simplify, may lead him to the conclusion that all human impulses are similarly self-regarding. This, at any rate, is Hobbes's cardinal doctrine in moral psychology, that each man's appetites or desires are naturally directed either to the preservation of his life, or to that heightening of it which he feels as pleasure. Hobbes does not distinguish instinctive from deliberate pleasure-seeking; and he confidently resolves the most apparently unselfish emotions into phases of self-regard. Pity he finds to be grief for the calamity of others, arising from imagination of the like calamity befalling oneself; what we admire with seeming disinterestedness as beautiful (*pulchrum*) is really "pleasure in promise"; when men are not immediately seeking present pleasure, they desire power as a means to future pleasure, and thus have a derivative delight in the exercise of power that prompts to what we call benevolent action. Since, then, all the voluntary actions of men tend to their own preservation or pleasure, it cannot be reasonable to aim at anything else; in fact, nature rather than reason fixes this as the end of human action; it is reason's function to show the means. Hence if we ask why it is reasonable for any individual to observe the rules of social behaviour that are commonly called moral, the answer is obvious that this is only indirectly reasonable, as a means to his own preservation or pleasure. It is not, however, in this, which is only the old Cyrenaic or Epicurean answer, that the distinctive point of Hobbism lies. It is rather in the doctrine that even this indirect reasonableness of the most fundamental moral rules is entirely conditional on their general observance, which cannot be secured apart from government. For example, it is not reasonable for me to perform my share of a contract, unless I have reason for believing that the other party will perform his; and this I cannot have, except in a society in which he will be punished for non-performance. Thus the ordinary rules of social behaviour are only hypothetically obligatory; they are actualized by the establishment of a "common power" that may "use the strength and means of all" to enforce on all the observance of rules tending to the common benefit. On the other hand, Hobbes yields to no one in maintaining the paramount importance of moral regulations. The precepts of good faith, equity, requital of benefits, forgiveness of wrong so far as security allows, the prohibition of contumely, pride, arrogance, —which may all be summed up in the formula, "Do not that to another which thou wouldest not have done to thyself" (*i.e.*, the negative of the "golden rule")—he still calls "immutable and eternal laws of nature"—meaning that, though a man is not unconditionally bound to realize them, he is, as a reasonable being, bound to desire that they should be realized. The pre-social state of man, in his view, is also pre-moral; but it is therefore utterly miserable. It is a state in which everyone has a right to everything that may conduce to his preservation; but it is therefore also a state of war—a state so wretched that it is the first dictate of rational self-love to emerge from it into social peace and order. Hence Hobbes's ideal constitution naturally comes to be unlimited despotism. Whatever the government declares to be just or unjust must be accepted as such, since to dispute its dictates would be the first step towards anarchy, the one paramount peril. It is perhaps easy to understand how, in the crisis of 1640, when the ethico-political system of Hobbes first took written shape, a peace-loving philosopher should regard the claims of individual conscience as essentially anarchical, and dangerous to social well-being; but however strong might be men's yearning for order, a view of social duty, in which the only fixed positions were selfishness everywhere and unlimited power somewhere, could not but appear offensively paradoxical.

There was, however, in his theory an originality, a force, an apparent coherence which rendered it undeniably impressive; in fact, we find that for two generations the efforts to construct morality on a philosophical basis take more or less the form of answers to Hobbes. From an ethical point of view Hobbism divides itself naturally into two parts, which by Hobbes's peculiar political doctrines are combined into a coherent whole, but are not otherwise necessarily connected. Its theoretical basis is the principle of egoism; while, for practically determining the particulars of duty it makes morality entirely dependent on positive law and institution. It thus affirmed the relativity of good and evil in a double sense; good and evil, for any individual citizen, may from one point of view be defined as the objects respectively of his desire and his aversion; from another, they may be said to be determined for him by his sovereign. It is this latter aspect of the system which is primarily attacked by the first generation of writers that replied to Hobbes. This attack, or rather the counter-exposition of orthodox doctrine, is conducted on different methods by the Cambridge moralists and by Cumberland respectively. Cumberland is content with the legal view of morality, but endeavours to establish the validity of the laws of nature by taxing them on the single supreme principle of rational regard for the "common good of all," and showing them, as so based, to be adequately supported by the divine sanction. The Cambridge school, regarding morality primarily as a body of truth rather than a code of rules, insist on its absolute character and intuitive certainty.

Cudworth, Locke, etc.—Cudworth was the most distinguished of the little group of thinkers at Cambridge in the 17th century, commonly known as the Cambridge Platonists (*q.v.*). In his treatise on *Eternal and Immutable Morality* his main aim is to maintain the "essential and eternal distinctions of good and evil" as independent of mere will, whether human or divine. These distinctions, he insists, have an objective reality, cognizable by reason no less than the relations of space or number; and he endeavours to refute Hobbism—which he treats as a "novantique philosophy," a mere revival of the relativism of Protagoras—chiefly by the following *argumentum ad hominem*. He argues that Hobbes's atomic materialism involves the conception of an objective physical world, the object not of passive sense that varies from man to man, but of the active intellect that is the same in all; there is therefore, he urges, an inconsistency in refusing to

admit a similar exercise of intellect in morals, and an objective world of right and wrong, which the mind by its normal activity clearly apprehends as such.

Cumberland's treatise *De Legibus Naturae* (1672) is in its ethical matter thoroughly modern. Cumberland is noteworthy as having been the first to lay down that "regard for the common good of all" is the supreme rule of morality or law of nature. So far he may be fairly called the precursor of later utilitarianism. His fundamental principle and supreme "Law of Nature" is thus stated: "The greatest possible benevolence of every rational agent towards all the rest constitutes the happiest state of each and all, so far as depends on their own power, and is necessarily required for their happiness; accordingly Common Good will be the Supreme Good." Locke agrees entirely with Hobbes as to the egoistic basis of rational conduct, and the interpretation of "good" and "evil" as "pleasure" and "pain," or that which is productive of pleasure and pain, yet he agrees also with Hobbes's opponents in holding ethical rules to be actually obligatory independently of political society, and capable of being scientifically constructed on principles intuitively known—though he does not regard these principles as implanted in the mind at birth. The aggregate of such rules he conceives as the law of God necessarily sanctioned by adequate rewards and punishments.

Shaftesbury.—Shaftesbury (1671–1713) tried another psychological basis for ethical construction; instead of presenting the principle of social duty as abstract reason, liable to conflict to any extent with natural self-love, he tried to exhibit the naturalness of man's social affections, and demonstrate a normal harmony between these and his self-regarding impulses. This theory had already been advanced by Cumberland and others, but Shaftesbury was the first to make it the cardinal point in his system; no one had yet definitely transferred the centre of ethical interest from the Reason, conceived as apprehending either abstract moral distinctions or laws of divine legislation, to the emotional impulses that prompt to social duty; no one had undertaken to distinguish clearly, by analysis of experience, the disinterested and self-regarding elements of our appetitive nature, or to prove inductively their perfect harmony. In his *Inquiry concerning Virtue and Merit* he begins by attacking the egoism of Hobbes, which was not necessarily excluded by the doctrine of rational intuitions of duty. This interpretation, he says, would be true only if we considered man as a wholly unrelated individual. Such a being we might doubtless call "good," if his impulses were adapted to the attainment of his own felicity. But man must be considered in relation to a larger system of which he forms a part, and so we call him "good" only when his dispositions are so balanced as to tend towards the good of this whole. This being established, the principal aim of Shaftesbury's argument is to prove that the same balance of private and social affections, which tends naturally to public good, is also conducive to the happiness of the individual in whom it exists.

But virtue, in Shaftesbury's view, is something more; it implies a recognition of moral goodness and immediate preference of it for its own sake. This immediate pleasure that we take in goodness (and displeasure in its opposite) is due to a susceptibility which he calls the "reflex" or "moral" sense, and compares with our susceptibility to beauty and deformity in external things; it furnishes both an additional direct impulse to good conduct, and an additional gratification to be taken into account in the reckoning which proves the coincidence of virtue and happiness. This doctrine of the moral sense is sometimes represented as Shaftesbury's cardinal tenet; but though characteristic and important, it is not really necessary to his main argument.

The appearance of Shaftesbury's *Characteristics* (1713) marks a turning-point in the history of English ethical thought. With the generation of moralists that followed, the consideration of abstract rational principles falls into the background, and its place is taken by introspective study of the human mind, observation of the actual play of its various impulses and sentiments. This empirical psychology had not indeed been neglected by previous writers. More, among others, had imitated Descartes in a discussion of the passions, and Locke's essay had given a still stronger impulse in the same direction; still, Shaftesbury is the first moralist who distinctly takes psychological experience as the basis of ethics. His suggestions were developed by Hutcheson into one of the most elaborate systems of moral philosophy which we possess; through Hutcheson, if not directly, they influenced Hume's speculations, and are thus connected with later utilitarianism. Moreover, the substance of Shaftesbury's main argument was adopted by Butler, though it could not pass the scrutiny of that powerful and cautious intellect without receiving important modifications and additions. On the other hand, the ethical optimism of Shaftesbury, rather broadly impressive than exactly reasoned, and connected as it was with a natural theology that implied the Christian scheme to be superfluous, challenged attack equally from orthodox divines and from cynical freethinkers. Of these latter Mandeville, the author of *The Fable of the Bees, or Private Vices Public Benefits* (1723), was a conspicuous if not a typical specimen.

Price published his *Review of the Chief Questions and Difficulties of Morals* in 1757. What Price is specially concerned to show is the existence of ultimate principles *beside* the principle of universal benevolence. Not that he repudiates the obligation either of rational benevolence or self-love; on the contrary, he takes more pains than Butler to demonstrate the reasonableness of either principle. "There is not anything," he says, "of which we have more undeniably an intuitive perception, than that it is 'right to pursue and promote happiness,' whether for ourselves or for others." Finally, Price, writing after the demonstration by Shaftesbury and Butler of the actuality of disinterested impulses in human nature, is bolder and clearer than Cudworth or Clarke in insisting that right actions are to be chosen because they are right by virtuous agents as such, even laying down that an act loses moral worth in proportion as it is done from natural inclination.

On this latter point Reid, in his *Essays on the Active Powers of the Human Mind* (1788), states a conclusion more in harmony with common sense, only maintaining that "no act can be morally good in which regard for what is right has not *some* influence."

Utilitarianism had already been taught before the time of Bentham by Gay and Paley. But Bentham's utilitarianism has a decided superiority over theirs. He considers actions solely in respect of their pleasurable and painful consequences, expected or actual; and he recognizes the need of making a systematic register of these consequences, free from the influences of common moral opinion, as expressed in the "eulogistic" and "dyslogistic" terms in ordinary use. Further, the effects that he estimates are all of a definite, palpable, empirically ascertainable quality; they are such pleasures and pains as most men feel and all can observe, so that all his political or moral inferences lie open at every point to the test of practical experience. Everyone, it would seem, can tell what value he sets on the pleasures of alimentation, sex, the senses generally, wealth, power, curiosity, sympathy, antipathy (malevolence), the goodwill of individuals or of society at large, and on the corresponding pains, as well as the pains of labour and organic disorders; and can guess the rate at which they are valued by others; therefore if it be once granted that all actions are determined by pleasures and pains, and are to be tried by the same standard, the art of legislation and private conduct is apparently placed on an empirical basis. Bentham, no doubt, seems to go beyond the limits of experience proper in recognizing "religious" pains and pleasures in his fourfold division of sanctions, side by side with the "physical," "political," and "moral" or "social"; but the truth is that he does not seriously take account of them, except in so far as religious hopes and fears are motives actually operating, which therefore admit of being observed and measured as much as any other motives. He does not himself use the will of an omnipotent and benevolent being as a means of logically connecting individual and general happiness. He thus undoubtedly simplifies his system, and avoids the doubtful inferences from nature and Scripture; but this gain is dearly purchased. For in answer to the question, How are the sanctions of the moral rules which it will most conduce to the general happiness for men to observe, shown to be always adequate in the case of all the in-

dividuals whose observance is required? he is obliged to admit that "the only interests which a man is at all times sure to find adequate motives for consulting are his own." Indeed, in many parts of his work, in the department of legislative and constitutional theory, it is rather assumed that the interests of some men will continually conflict with those of their fellows, unless we alter the balance of prudential calculation by a readjustment of penalties. But on this assumption a system of private conduct on utilitarian principles cannot be constructed until legislative and constitutional reform has been perfected. And, in fact, "private ethics," as conceived by Bentham, does not exactly expound such a system; but rather exhibits the coincidence, *so far as it extends,* between private and general happiness, in that part of each man's conduct that lies beyond the range of useful legislation. It was not his place, as a practical philanthropist, to dwell on the defects in this coincidence; and since what men generally expect from a moralist is a completely reasoned account of what they ought to do, it is not surprising that some of Bentham's disciples should have either ignored or endeavoured to supply the gap in his system. One section of the school even maintained it to be a cardinal doctrine of utilitarianism that a man always gains his own greatest happiness by promoting that of others; another section, represented by John Austin, apparently returned to Paley's position, and treated utilitarian morality as a code of divine legislation; others, with Grote, are content to abate the severity of the claims made by "general happiness" on the individual, and to consider utilitarian duty as practically limited by reciprocity; while on the opposite side an unqualified subordination of private to general happiness was advocated by J. S. Mill, who did more than any other to spread utilitarianism.

The fact is that there are several different ways in which a utilitarian system of morality may be used, without deciding whether the sanctions attached to it are always adequate. (1) It may be presented as practical guidance to all who choose "general good" as their ultimate end, whether on religious grounds, or because their conscience acts in harmony with utilitarian principles, or for any other seasons; or (2) it may be offered as a code to be obeyed only so far as the coincidence of private and general interest may in any case be judged to extend; or again (3) it may be proposed as a standard by which men may reasonably agree to praise and blame the conduct of others, even though they may not always think fit to act on it. We may regard morality as a kind of supplementary legislation, supported by public opinion, which we may expect the public, when duly enlightened, to frame in accordance with the public interest. Still, even from this point of view, which is that of the legislator or social reformer rather than the moral philosopher, our code of duty must be greatly influenced by our estimate of the degrees in which men are normally influenced by self-regard, sympathy or benevolence, and of the range within which sympathy may be expected to be generally effective. Thus, for example, the moral standard for which a utilitarian will reasonably endeavour to gain the support of public opinion must be essentially different in quality, according as he holds with Bentham that nothing but self-regard will "serve for diet," though "for a dessert benevolence is a very valuable addition"; or with J. S. Mill that disinterested public spirit should be the prominent motive in the performance of all socially useful work, and that even hygienic precepts should be inculcated, because "by squandering our health we disable ourselves from rendering services to our fellow-creatures."

Continental Ethics.—In the 17th century and late into the 18th century Continental ethics had no influence on British moralists. Hence the preceding sketch of English ethics contains no allusion to Continental moralists. English ethics was self-contained during the period, and was predominantly empirical or psychological, whereas elsewhere in Europe ethics was metaphysical. Not till the time of T. H. Greene did English ethics seriously seek a metaphysical basis, though Continenal influences came into play among English moralists long before that.

Descartes.—Descartes (1596–1650) did not write a special treatise on ethics, but he dealt with ethical problems in his correspondence and in his *Treatise on the Passions of the Soul.* His ethical views show traces of Socratic, Platonic and Stoic influences. He identifies right willing with clear thinking. If man were only a spirit or rational soul, and had not also a body, he would always think clearly and so will rightly. Evil results from the influence of the body. Thus the body gives rise to "passions," which are an obstacle to clear knowledge, and so induces man to desire what is not truly desirable. Left to itself the spirit or rational soul of man is entirely active and free and good; but under the influence of the body, and of all that affects the body from outside, man becomes partly "passive," the slave of "passions," and so evil. The thing to aim at is therefore the supremacy of the mind or will over the "passions." The "passions" (including the emotions) cannot, however, be entirely suppressed, seeing that the human soul is, as a matter of fact, mated with a body. But much may be done to secure the predominance of the higher emotions at the expense of the lower passions. Wonder, or intellectual interest, is such an emotion. By cultivating it we promote the power of clear thinking or of real knowledge, and so advance the cause of morality. (*See* DESCARTES.)

Spinoza.—Spinoza (1632–1677) was the author of the most metaphysical system of ethics. His *Ethica* seems at first to be a misnamed treatise on metaphysics. But if it is true to say that his ethics is metaphysical, it is even more true to remark that his metaphysics is ethical. For unlike Descartes, who paid but little attention to ethics, Spinoza regarded the ethical problem as the most important, and subordinated to it all other philosophical problems. For Spinoza, philosophy was a completely rational religion, enriched by elements of a higher mysticism.

To understand the moral life of man attention must be focussed on a certain self-preserving impulse (*conatus*) which constitutes the very essence of each finite individual. Human feelings and emotions are the outcome of this impulse. Now the character of this self-preservation and self-realization varies with the different stages of man's intellectual development, and moral progress keeps pace with his intellectual progress. Spinoza distinguishes three (sometimes four) ascending grades of knowledge—Opinion, Reason, Intuition. At the lowest, pre-scientific stage of opinion (or vague experience) one is guided mainly by chance associations without rational insight. At this stage the self which seeks realization is the merely individual self as affected by accidents of place and time; for it, pleasure is the sole good, pain the sole evil. Not guided by its own intellectual activity, but influenced mainly by outside factors, the mind of man is at this stage in a state of bondage. Human nature, however, tends to emancipate itself from such bondage to the senses and the external objects that lure them on. At the stage of Reason, the active and universal element in human nature asserts itself, and helps man to free himself from the domination of the particular and the sensuous. Passions lose their power when they are seen through by penetrating thought. And man frees himself from his bondage to the particular objects of his loves and his hates when he grasps their real place in the order of Nature and the universal laws which control them. As man gains insight into his own place in the whole order of things and realizes the necessity of the whole cosmic process, he banishes all fear and regret, all disappointments and resentment, and acquires peace of mind. In this way reason uplifts the mind above the unrest of passion, and fills it with the joy of acquiescence in the universal order of things. At the highest stage of intellectual development, that of Intuitive Knowledge, the mind contemplates the whole universe as a complete unity, of which all things (including human beings) are infinitely varied expressions. This attitude induces the highest spiritual activity whereby the mind identifies its essence with the Infinite Being, and is filled with the intellectual love of God.

Kant.—The English moralist with whom Kant has most affinity is Price; in fact, Kantism, in the ethical thought of modern Europe, holds a place somewhat analogous to that formerly occupied by the teaching of Price and Reid among English moralists. Kant, like Price and Reid, holds that man as a rational being is unconditionally bound to conform to a certain rule of right, or "categorical imperative" of reason. Like Price he holds that an action is not good unless done from a good motive, and that this

motive must be essentially different from natural inclination of any kind; duty, to be duty, must be done for duty's sake; and he argues, with more subtlety than Price or Reid, that though a virtuous act is no doubt pleasant to the virtuous agent, and any violation of duty painful, this moral pleasure (or pain) cannot strictly be the motive to the act, because it follows instead of preceding the recognition of our obligation to do it. With Price, again, he holds that rightness of intention and motive is not only an indispensable condition or element of the rightness of an action, but actually the sole determinant of its moral worth; but with more philosophical consistency he draws the inference that there can be no separate rational principles for determining the "material" rightness of conduct, as distinct from its "formal" rightness; and therefore that all rules of duty, so far as universally binding, must admit of being exhibited as applications of the one general principle that duty ought to be done for duty's sake. This deduction is the most original part of Kant's doctrine. The dictates of reason, he points out, must necessarily be addressed to all rational beings as such; hence, my intention cannot be right unless I am prepared to will the principle on which I act to be a universal law. He considers that this fundamental rule or imperative "act on a maxim which thou canst will to be law universal" supplies a sufficient criterion for determining particular duties in all cases. The rule excludes wrong conduct with two degrees of stringency. Some offences, such as making promises with the intention of breaking them, we cannot even conceive universalized; as soon as every one broke promises no one would care to have promises made to him. Other maxims, such as that of leaving persons in distress to shift for themselves, we can easily conceive to be universal laws, but we cannot without contradiction will them to be such; for when we are ourselves in distress we cannot help desiring that others should help us.

Another important peculiarity of Kant's doctrine is his development of the connection between duty and free-will. He holds that it is through our moral consciousness that we know that we are free; in the cognition that I ought to do what is right because it is right and not because I like it, it is implied that this purely rational volition is possible; that my action can be determined, not "mechanically," through the necessary operation of the natural stimuli of pleasurable and painful feelings, but in accordance with the laws of my true, reasonable self. The realization of reason, or of human wills so far as rational, thus presents itself as the absolute end of duty; and we get, as a new form of the fundamental practical rule, "act so as to treat humanity, in thyself or any other, as an end always, and never as a means only." We may observe, too, that the notion of freedom connects ethics with jurisprudence in a simple and striking manner. The fundamental aim of jurisprudence is to realize external freedom by removing the hindrances imposed on each one's free action through the interferences of other wills. Ethics shows how to realize internal freedom by resolutely pursuing rational ends in opposition to those of natural inclination. If we ask what precisely are the ends of reason, Kant's proposition that "all rational beings as such are ends in themselves for every rational being" hardly gives a clear answer. It might be interpreted to mean that the result to be practically sought is simply the development of the rationality of all rational beings—such as men—whom we find to be as yet imperfectly rational. But this is not Kant's view. He holds, indeed, that each man should aim at making himself the most perfect possible instrument of reason; but he expressly denies that the perfection of others can be similarly prescribed as an end to each. It is, he says, "a contradiction to regard myself as in duty bound to promote the perfection of another, . . . a contradiction to make it a duty for me to do something for another which no other but himself can do." In what practical sense, then, am I to make other rational beings my ends? Kant's answer is that what each is to aim at in the case of others is not Perfection, but Happiness, *i.e.*, to help them to attain those purely subjective ends that are determined for each not by reason, but by natural inclination. He explains also that to seek one's own happiness cannot be prescribed as a duty, because it is an end to which every man is inevitably impelled by natural inclination: but that just because each inevitably desires his own happiness, and therefore desires that others should assist him in time of need, he is bound to make the happiness of others his ethical end, since he cannot *morally* demand aid from others without accepting the obligation of aiding them in like case. The exclusion of private happiness from the ends at which it is a duty to aim contrasts strikingly with the view of Butler and Reid, that man, as a rational being, is under a "manifest obligation" to seek his own interest. The difference, however, is not really so great as it seems; since in another part of his system Kant fully recognizes the reasonableness of the individual's regard for his own happiness. Though duty, in his view, excludes regard for private happiness, the *summum bonum* is not duty alone, but happiness combined with moral worth; the demand for happiness as the reward of duty is so essentially reasonable that we must postulate a universal connection between the two as the order of the universe; indeed, the practical necessity of this is the only adequate rational ground for believing in the existence of God.

Hegel.—Before the ethics of Kant had begun to be seriously studied in England, the rapid and remarkable development of metaphysical view and method of which the three chief stages are represented by Fichte, Schelling and Hegel respectively had already taken place; and the system of the latter was occupying the most prominent position in the philosophical thought of Germany. Hegel's ethical doctrine (expounded chiefly in his *Philosophie des Rechts*, 1821) shows a close affinity, and also a striking contrast, to Kant's. He holds, with Kant, that duty or good conduct consists in the conscious realization of the free reasonable will, which is essentially the same in all rational beings. But in Kant's view the universal content of this will is only given in the formal condition of "only acting as one can desire all to act," to be subjectively applied by each rational agent to his own volition; whereas Hegel conceives the universal will as objectively presented to each man in the laws, institutions and customary morality of the community of which he is a member. Thus, in his view, not merely natural inclinations towards pleasures, or the desires for selfish happiness, require to be morally resisted; but even the prompting of the individual's conscience, the impulse to do what seems to him right, if it comes into conflict with the common sense of his community. It is true that Hegel regards the conscious effort to realize one's own conception of good as a higher stage of moral development than the mere conformity to the jural rules establishing property, maintaining contract and allotting punishment to crime, in which the universal will is first expressed; since in such conformity this will is only accomplished accidentally by the outward concurrence of individual wills, and is not essentially realized in any of them. He holds, however, that this conscientious effort is self-deceived and futile, is even the very root of moral evil, except it attains its realization in harmony with the objective social relations in which the individual finds himself placed. Of these relations the first grade is constituted by the family, the second by civil society, and the third by the State, the highest manifestation of universal reason in the sphere of practice.

Hegelianism appears as a distinct element in modern English ethical thought; but the direct influence of Hegel's system is perhaps less important than that indirectly exercised through the powerful stimulus which it has given to the study of the historical development of human thought and human society. According to Hegel, the essence of the universe is a process of thought from the abstract to the concrete; and a right understanding of this process gives the key for interpreting the evolution in time of European philosophy. So again, in his view, the history of mankind is a history of the necessary development of the free spirit through the different forms of political organization: the first being that of the Oriental monarchy, in which freedom belongs to the monarch only; the second, that of the Graeco-Roman republics, in which a select body of free citizens is sustained on a basis of slavery; while finally in the modern societies, sprung from the Teutonic invasion of the decaying Roman empire, freedom is recognized as the natural right of all members of the community. The effect of the lectures (posthumously edited) in which Hegel's "Philosophy of History" and "History of Philosophy" were expounded, has extended far beyond the limits of his special school.

RECENT ETHICS

Evolutionary Ethics.—From the latter half of the 19th century onwards ethical thought was influenced by Darwinian theories. Darwin himself seems never to have questioned (as did some of his sceptical followers) the absolute character of moral obligation. What interested him chiefly, in so far as he made a study of morality, was the development of moral conduct in its preliminary stages. He was principally concerned to show that in morality, as in other departments of human life, it was not necessary to postulate a complete and abrupt gap between human and merely animal existence but that the instincts and habits which contribute to survival in the struggle for existence among animals develop into moral qualities which have a similar value for the preservation of human and social life. Regarding the social tendency as originally itself an instinct developed out of parental or filial affection, he seems to suggest that natural selection, which was the chief cause of its development in the earlier stages, may very probably influence the transition from purely tribal and social morality into morality in its later and more complex forms. But he admits that natural selection is not necessarily the only cause, and he refrains from identifying the fully developed morality of civilized nations with the "social instinct." Moreover, he recognizes that qualities, *e.g.*, loyalty and sympathy, which may have been of great service to the tribe in its primitive struggle for existence, may become a positive hindrance to physical efficiency (leading as they do to the preservation of the unit) at a later stage. Nevertheless to check our sympathy would lead to the "deterioration of the noblest part of our nature," and the question, which is obviously of vital importance, whether we should obey the dictates of reason, which would urge us only to such conduct as is conducive to natural selection, or remain faithful to the noblest part of our nature at the expense of reason, he leaves unsolved.

Spencer.—It was in Herbert Spencer, that the advocates of evolutionary ethics found their protagonist. Spencer looked to ideas derived from the biological sciences to provide a solution of all the enigmas of morality, as of most other departments of life; and he conceived it "to be the business of moral science to deduce from the laws of life and the conditions of existence what kinds of action necessarily tend to produce happiness and what kinds to produce unhappiness." It is clear, therefore, that any moral science which is to be of value must wait until the "laws of life" and "conditions of existence" have been satisfactorily determined, presumably by biology and the allied sciences; and there are few more melancholy instances of failure in philosophy than the paucity of the actual results attained by Spencer in his lifetime in his application of the so-called laws of evolution to human conduct—a failure recognized by Spencer himself. His own contribution to ethics was vitiated at the outset by the fact that he never shook himself free from the trammels of the philosophy which his own system was intended to supersede. He began by disclaiming any affinity to Utilitarianism on the part of his own philosophy. He pointed out that the principle of the greatest happiness of the greatest number is a principle without any definite meaning, since men are nowhere unanimous in their standard of happiness, but regard the conception of happiness rather as a problem to be solved than a test to be applied. Universal happiness would require omniscience to legislate for it and the "normal" or, as some would say, "perfect" man to desire it. Further, the principle that "everybody is to count for one, nobody for more than one," is equally unsatisfactory. It may be taken to imply that the useless and the criminal should be entitled to as much happiness as the useful and the virtuous. While it gives no rule for private as distinct from public conduct, it provides no real guidance for the legislator. For neither happiness, nor the concrete means to happiness, nor finally the conditions of its realization can be distributed; and in the end "not general happiness becomes the ethical standard by which legislative action is to be guided, but universal justice." Yet the implications of this latter conclusion Spencer never fully thought out. He accepted the hedonistic psychology by which the Utilitarians sought to justify their theory while he rejected the theory itself. Good, *e.g.*, defined by him "as conduct conducive to life," is also further defined as that which is "conducive to a surplus of pleasures over pains." Happiness, again, is always regarded as consisting in feeling, ultimately in pleasant feeling, and there is no attempt to apply the same principles of criticism which he had successfully applied to the Utilitarians' "happiness" to the conception of "pleasure." And, though he maintains as against the Utilitarians the existence of certain fundamental moral intuitions which have come to be quite independent of any present conscious experience of their utility, he yet holds that they are the results of accumulated racial experiences gradually organized and inherited. Finally side by side with a theory of the nature of moral obligation thus fundamentally empirical and *a posteriori* in its outlook, he maintains in his account of justice the existence of the idea of justice as distinct from a mere sentiment, carrying with it an *a priori* belief in its existence and identical in its *a priori* and intuitive character with the ultimate criterion of Utilitarianism itself. The fact is that any close philosophical analysis of Spencer's system of ethics can only result in the discovery of a multitude of mutually conflicting theories. It is frequently impossible to discover whether he wishes by an appeal to evolutionary principles to reinforce the sanctions and emphasize the absolute character of the traditional morality which in the main he accepts without question from the current opinions about conduct of his age, or whether he wishes to discredit and disprove the validity of that morality in order to substitute by the aid of the biological sciences a new ethical code.

Nor is his attempt to construct a scientific criterion out of data derived from the biological sciences productive of satisfactory results. He is hampered by a distinction between "absolute" and "relative" ethics definitely formulated in the last two chapters of *The Data of Ethics*. Absolute ethics would deal with such laws as would regulate the conduct of ideal man in an ideal society, *i.e.*, a society where conduct has reached the stage of complete adjustment to the needs of social life. Relative ethics, on the other hand, is concerned only with such conduct as is advantageous for that society which has not yet reached the end of complete adaptation to its environment, *i.e.*, which is at present imperfect. Spencer does not tell us how to bring the two ethical systems into correlation. And the actual criteria of conduct derived from biological considerations are almost ludicrously inadequate. Conduct, *e.g.*, is said to be more moral in proportion as it exhibits a tendency on the part of the individual or society to become more "definite," "coherent" and "heterogeneous." Or, again, we should recognize as a test of the "authoritative" character of moral ideas or feelings the fact that they are complex and representative, referring to a remote rather than to a proximate good, remembering the while that "the sense of duty is transitory, and will diminish as fast as moralization increases." In fact, no acceptable scientific criterion emerges, and the outcome of Spencer's attempt to ascertain the laws of life and the conditions of existence is either a restatement of the dictates of the moral consciousness in vague and cumbrous quasi-scientific phraseology, or the substitution of the meaningless test of "survivability" as a standard of perfection for the usual and intelligible standards of "good" and "right."

Stephen.—A similar criticism might fairly be passed upon the majority of philosophers who approach ethics from the standpoint of evolution. Sir Leslie Stephen, for instance, wishes to substitute the conception of "social health" for that of universal happiness, and considers that the conditions of social health are to be discovered by an examination of the "social organism" or of "social tissue," the laws of which can be studied apart from those laws by which the individuals composing society regulate their conduct. "The social evolution means the evolution of a strong social tissue; the best type is the type implied by the strongest tissue." But on the important question as to what constitutes the strongest social tissue, or to what extent the analogy between society as at present constituted and organic life is really applicable, we are left without certain guidance. The fact is that with few exceptions evolutionary moral philosophers evade the choice between alternatives which is always presented to them. They begin, for the most part, with a belief that in ethics as in other

departments of human knowledge "the more developed must be interpreted by the less developed"—though frequently in the sequel complexity or posteriority of development is erected as a standard by means of which to judge the process of development itself. They are not content to write a *history* of moral development, applying to it the principles by which Darwinians seek to explain the development of animal life. But the search of origins frequently leads them into theories of the nature of that moral conduct whose origin they are anxious to find quite at variance with current and accepted beliefs concerning its nature. The discovery of the so-called evolution of morality out of non-moral conditions is very frequently an unconscious subterfuge by which the evolutionist hides the fact that he is making *a priori* judgments upon the value of the moral concepts held to be evolved. To accept such theories of the origin of morality would carry with it the conviction that what we took for "moral" conduct was in reality something very different, and has been so throughout its history. The legitimate inference which should follow would be the denial of the validity of those moral laws which have hitherto been regarded as absolute in character, and the substitution for all customary moral terms of an entirely new set based upon biological considerations. But it is precisely this, the only logical inference, which most evolutionary philosophers are unwilling to draw. They cannot give up their belief in customary morality. Prof. Huxley maintained, for example, that "the ethical progress of society depends not on imitating the cosmic process, still less in running away from it, but in combating it" (*Romanes Lecture*).

Nietzsche.—Perhaps the one European thinker who has carried evolutionary principles in ethics to their logical conclusion is Friedrich Nietzsche. Almost any system of morality or immorality might find some justification in Nietzsche's writings, which are extraordinarily chaotic and full of the wildest exaggerations. Yet it has been a true instinct which has led popular opinion as testified to by current literature to find in Nietzsche the most orthodox exponent of Darwinian ideas in their application to ethics. For he saw clearly that to be successful evolutionary ethics must involve the "transvaluation of all values," the "demoralization" of all ordinary current morality. He accepted frankly the glorification of brute strength, superior cunning and all the qualities necessary for success in the struggle for existence, to which the ethics of evolution necessarily tends. He proclaimed himself, before everything else, a physiologist, and looked to physiology to provide the ultimate standard for everything that has value; and though his own ethical code necessarily involves the disappearance of sympathy, love, toleration and all existing altruistic emotions, he yet in a sense finds room for them in such altruistic self-sacrifice as prepares the way for the higher man of the future. Thus, after a fashion, he is able to reconcile the conflicting claims of egoism and altruism and succeed where most apostles of evolution fail. The Christian virtues, sympathy for the weak, the suffering, etc., represent a necessary stage to be passed through in the evolution of the *Übermensch, i.e.*, the stage when the weak and suffering combine in revolt against the strong. They are to be superseded, not so much because all social virtues are to be scorned and rejected, as because in their effects, *i.e.*, in their tendency to perpetuate and prolong the existence of the weak and those who are least well equipped and endowed by nature, they are anti-social in character and inimical to the survival of the strongest and most vigorous type of humanity. Consequently Nietzsche in effect maintains the following paradoxical position: he explains the existence of altruism upon egoistical principles; he advocates the total abolition of all altruism by carrying these same egoistical principles to their logical conclusion; he nevertheless appeals to that moral instinct which makes men ready to sacrifice their own narrow personal interests to the higher good of society—an instinct profoundly altruistic in character—as the ultimate justification of the ethics he enunciates. Such a position is a *reductio ad absurdum* of the attempt to transcend the ultimate character of those intuitions and feelings which prompt men to benevolence. Thus, though incidentally there is much to be learned from Nietzsche, especially from his criticism of the ethics of pessimism, or from the strictures he passes upon the negative morality of extreme asceticism or quietism, his system inevitably provides its own refutation. For no philosophy which travesties the real course of history and distorts the moral facts is likely to commend itself to the sober judgment of mankind however brilliant be its exposition or ingenious its arguments. Finally, the conceptions of strength, power and masterfulness by which Nietzsche attempts to determine his own moral ideal, become, when examined, as relative and unsatisfactory as other criteria of moral action said to be deduced from evolutionary principles. Men desire strength or power not as ends but as means to ends beyond them; Nietzsche is most convincing when the *Übermensch* is left undefined. Imagined as ideal man, *i.e.*, as morality depicts him, he becomes intelligible; imagined as Nietzsche describes him he reels back into the beast.

It was upon this crucial difficulty, *i.e.*, the transition in the evolution of morality from the stage of purely animal and unconscious action to specifically human action—*i.e.*, action directed by self-conscious and purposive intelligence to an end conceived as good—that the polemic of T. H. Green and his followers fastened.

Metaphysical Ethics.—Green's principal objection to evolutionary moral philosophy is contained in the argument that no merely "natural" explanation of the facts of morality is conceivable. The knowing consciousness—*i.e.*, so far as conduct is concerned and moral consciousness—can never become an object of knowledge in the sense in which natural phenomena are objects of scientific knowledge. For such knowledge implies the existence of a knowing consciousness as a relating and uniting intelligence capable of distinguishing itself from the objects to which it relates. And more particularly the existence of the moral consciousness implies "the transition from mere want to consciousness of wanted object, from impulse to satisfy the want to effort for the realization of the wanted objects, implies the presence of the want to a subject which distinguishes itself from it." Consequently the facts of moral development imply with the emergence of human consciousness the appearance of something qualitatively different from the facts with which physiology, for instance, deals, imply a stratum, as it were, in development which no examination of animal tissues, no calculation of consequences with regard to the preservation of the species, can ever satisfactorily explain.

Green's loyalty to the primary facts of the moral consciousness prevented him from constructing a rationalistic system of morals based solely upon the conclusions of metaphysics, but the revival of interest in metaphysics led to a more daring criticism of ethical first principles in other writers. Bradley's *Ethical Studies* had presented with great brilliancy an idealist theory of morality not very far removed from that of Green's *Prolegomena*. But the publication of *Appearance and Reality* by the same author marked a great advance in philosophical criticism of ethical postulates, and a growing dissatisfaction with current reconciliations between moral first principles and the conclusions of metaphysics. *Appearance and Reality* was not primarily concerned with morals, yet it inevitably led to certain conclusions affecting conduct, and it was no very long time before these conclusions were elaborated in detail. A. E. Taylor's *Problem of Conduct* (1901) follows in the main Bradley's line of criticism and may therefore be regarded as representative of his school. There are two principal positions in Taylor's work: (1) a refusal to base ethics upon metaphysics, and (2) the discovery of an irreconcilable dualism in the nature of morality which takes many shapes, but may be summarized roughly as consisting in an ultimate opposition between egoism and altruism. With regard to the first of these Taylor says that his object is to show that "ethics is as independent of metaphysical speculation for its principles and methods as any of the so-called 'natural sciences'; that its real basis must be sought not in philosophical theories about the nature of the Absolute or the ultimate constitution of the Universe, but in the empirical facts of human life as they are revealed to us in our concrete everyday experience of the world and mankind, and sifted and systematized by the sciences of psychology and sociology. . . . Ethics should be regarded as a purely 'positive' or

'experimental' and not as a 'speculative' science." With regard to the second position one quotation will suffice (*op. cit.*, p. 183). "Altruism and egoism are divergent developments from the common psychological root of primitive ethical sentiment. Both developments are alike unavoidable, and each is ultimately irreconcilable with the other. Neither egoism nor altruism can be made the sole basis of moral theory without mutilation of the facts, nor can any higher category be discovered by the aid of which their rival claims may be finally adjusted."

Taylor expounds these two theories with much ingenuity, yet neither of them will carry complete conviction to his critics. It is curious to find the independence of moral philosophy upon metaphysics supported by metaphysical arguments. For it is obvious that Taylor's own dissatisfaction with current moral principles arises from an inability to believe in their ultimate rationality, *i.e.*, a belief that they are untenable from the standpoint of metaphysics. But further, it is apparent that psychology (upon which Taylor would base morality) itself involves metaphysical assumptions; its position in fact cannot be stated except as a metaphysical position. And the need which most philosophers have felt for some philosophical foundation for morality arises, not from any desire to subordinate moral insight to speculative theory, but because the moral facts themselves are inexplicable except in the light of first principles which metaphysics alone can criticize.

Taylor himself attempts to find the roots of ethics in the moral sentiments of mankind, the moral sentiments being primarily feelings or emotions, though they imply and result in judgments of approval and disapproval upon conduct. But it may be doubted whether he succeeds in clearly distinguishing ethical feelings from ethical judgments, and if they are to be treated as synonymous it seems difficult to avoid the conclusion that the implications of moral "judgment" must involve a reference to metaphysics.

Taylor's polemic against metaphysical systems of ethics is based throughout upon an alleged discrepancy and separation between the facts of moral "experience," the judgments of the moral consciousness, and theories as to the nature of these which the philosophers whom he attacks would by no means accept. There is no doubt a distinction between morality as a form of consciousness and reflection upon that morality. But such a distinction neither corresponds to, nor testifies to, the existence of a distinction between morality as "experience" and morality as "theory."

Taylor is more persuasive when he is developing his second main thesis—that of the alleged existence of an ultimate dualism in the nature of morality. His accounts of the genesis of the conceptions of obligation and responsibility as of most of the ultimate conceptions with which moral philosophy deals will be accepted or rejected to the extent to which the main contention concerning the psychological basis of ethics commends itself to the reader. But in his exposition of the fundamental contradiction involved in morality elaborated with much care and illustrative argument he appeals for the most part to facts familiar to the unphilosophical moral consciousness. He begins by finding an ultimate opposition between the instincts of self-assertion and instincts which secure the production and protection of the coming generation even in the infra-ethical world with which biology deals. He traces this opposition into the forms in which it appears in the social life of mankind, and finds "a hidden root of insincerity and hypocrisy beneath all morality," inasmuch as it is not possible to pursue any one type of ideal without some departure from singleness of purpose. And he finds all the conceptions by which men have hoped to reconcile admitted antagonisms and divergencies between moral ideals claiming to be ultimate and authoritative alike unsatisfactory. Progress is illusory; there is no satisfactory goal to which moral development inevitably tends; religion in which some take refuge when distressed by the contradictions of moral conduct itself "contains and rests upon an element of make believe."

Martineau and Sidgwick.—It would be true on the whole to assert that evolutionary systems of ethics such as those of Herbert Spencer, Leslie Stephen or S. Alexander (*Moral Order and Progress,* 1899), together with the metaphysical theories of morals of which T. H. Green and Bradley and Taylor are the chief representatives, have dominated the field of ethical speculation since 1870. Nevertheless it is only necessary to mention such a work as Martineau's *Types of Ethical Theory* to dispel the notion that the type of moral philosophy most characteristically English, *i.e.*, consisting in the patient analysis of the form and nature of the moral consciousness itself, has given way or is likely to give way to more ambitious and constructive efforts. Martineau's chief endeavour was to interpret, to vindicate, and to systematize the moral sentiments, and if the actual exhibition of what is involved, *e.g.*, in moral choice is the vindication of morality Martineau may be said to have been successful. It is with his interpretation and systematization of the moral sentiments that most of Martineau's critics have found fault. It is impossible, *e.g.*, to accept his ordered hierarchy of "springs of action" without perceiving that the real principle upon which they can be arranged in order at all must depend upon considerations of circumstances and consequences, of stations and duties, with which a strict intuitionalism such as that of Martineau would have no dealing. Similarly the notion of Conscience as a special faculty giving its pronouncements immediately and without reflection cannot be maintained in the face of modern psychological analysis and is untrue to the nature of moral judgment itself. And Martineau is curiously unsympathetic to the universal and social aspect of morality with which evolutionary and idealist moral philosophers are so largely occupied. Nevertheless there have been few moral philosophers who have set forth with clearer insight the essential nature of the moral consciousness.

Equal in importance to Martineau's work is Prof. Sidgwick's *Methods of Ethics* which appeared in 1874. The two works are alike devoted to the re-examination of the nature of the moral consciousness to the exclusion of alien branches of inquiry. In most other respects they differ. Martineau is much more in sympathy with idealism than Sidgwick, whose work consists in a restatement from a novel and independent standpoint of the Utilitarian position. Many of his most acute critics would be the first to admit how much they owe to his teaching. Chief among the more recent of these is G. E. Moore, whose book *Principia Ethica* is an important contribution to ethical thought. And although Hastings Rashdall (*The Theory of Good and Evil,* 1907) is not in agreement with Sidgwick's type of hedonistic theory, he holds a point of view similar to that of Sidgwick's Rational Utilitarianism. Rashdall's two volumes exhibit also a welcome return on the part of English thought to the proper business of the moral philosopher—the examination of the nature of moral conduct. Other works, such as L. T. Hobhouse's *Morals in Evolution* or E. A. Westermarck's *Origin and Development of the Moral Ideas,* testify to a continued interest in the history of morality and in the anthropological inquiries with which moral philosophy is closely connected.

ETHIOPIA or **AETHIOPIA** (Gr. Αἰθιοπία), the ancient name of a district of north-eastern Africa bounded on the north by Egypt and on the east by the Red Sea (for topography and later history *see* Sudan and Abyssinia). In the Homeric poems the *Aethiopes* are the furthest of mankind; the gods go to their banquets and probably the Sun sets in their country. With the growth of scientific geography, they came to be located less vaguely, and their name was employed as the equivalent of the Hebrew Cush (*q.v.*), the Kesh or Ekōsh of the Hieroglyphics, *i.e.*, a country extending from about the 24th to the 10th degree of N. lat. The etymology of the name, which to a Greek ear meant "Swarthy-faced," is unknown. In official inscriptions of the Axumite dynasty the word is used as the equivalent of Habashat (whence Abyssinia), rendered by the Greek geographers *Abaseni* and *Abissa.*

The inhabitants of Ethiopia attracted the attention of many Greek researchers. Herodotus (vii. 70) divides them into two

main groups, a straight-haired race and a woolly-haired race, dwelling respectively to the east and west, and this distinction is confirmed by the Egyptian monuments. The bulk of our information is derived from Egyptian monuments, whence it appears that, originally occupied by independent tribes, who were raided and gradually subjected by Egyptian kings (*see* E. W. Budge, *The Egyptian Sudan*, 1907, i. 505 *et seq.*), under the 18th Dynasty it became an Egyptian province, administered by a viceroy, called prince of Kesh, and paying tributes in negroes, oxen, gold, ivory, rare beads, hides and household utensils. The inhabitants frequently rebelled and were as often subdued; records of these repeated conquests were set up by the Egyptian kings in the shape of columns and temples.

Ethiopia became independent towards the 11th century B.C.; a state was founded, having for its capital Napata which in time became formidable, and in the middle of the 8th century conquered Egypt; an Egyptian campaign is recorded in the famous stele of King Pankhi. The fortunes of the Ethiopian (25th) Dynasty belong to the history of Egypt (*q.v.*). After the Ethiopian yoke had been shaken off by Egypt, about 660 B.C., Ethiopia continued independent, under kings of whom not a few are known from inscriptions. From the evidence of these it has been inferred that the sovereignty became elective; a deputation was sent to Napata, where the chief god Amen selected out of members of the royal family the person who was to succeed, and who became officially the god's son. It seems certain that the priestly caste was more influential in Ethiopia than in Egypt both before and after this period. The stele of Harsiötf contains the record of nine expeditions, in the course of which the king subdued various tribes south of Meroë. The stele of Nastasen now in the Berlin Museum, edited by H. Schäfer (Leipzig, 1901), contains information concerning the state of the Ethiopian kingdom. Shortly after his accession he was threatened with invasion by Cambyses, the Persian conqueror of Egypt, but destroyed the fleet sent by the invader up the Nile, while (as we learn from Herodotus, iii. 25) the land-force succumbed to famine (*see* CAMBYSES). The capital was removed from Napata to Meroë at a distance of 60 camel-hours to the south-east. But Napata retained its importance as the religious metropolis; thither the king went to be crowned, and there too the chief god delivered his oracles. These Ethiopian kings seem to have made no attempt to reconquer Egypt, but were often engaged in wars with the wild tribes of the Sudan. A fresh epoch was inaugurated by Ergamenes, a contemporary of Ptolemy Philadelphus, who massacred the priests at Napata, and destroyed sacerdotal influence, till then so great that the king might at the priests' order be compelled to destroy himself. Probably the sovereignty again became hereditary. Occasional notices of Ethiopia occur in Greek and Latin authors, according to which the country came to be ruled by queens named Candace. One of them was involved in war with the Romans in 24 and 23 B.C.; the land was invaded by C. Petronius, who took the fortress Premis or Ibrim, and sacked the capital (then Napata); Augustus, however, ordered the evacuation of the country without even demanding tribute. The stretch of land between Aswan (Syene) and Maharraka (Hiera Sycaminus) was, however, regarded as belonging to the Roman empire, and Roman cohorts were stationed at the latter place. Candace appears to be found as the name of a queen for whom a pyramid was built at Meroë. A great builder was Netekamane, who is represented with his queen Amanetari on temples of Egyptian style at many points up the Nile. In the Roman period the type in sculpture changed from the Egyptian. The figures are obese, especially the women, and have pronounced negro features, and the royal person is loaded with bulging gold ornaments. In the 4th century A.D. the state of Meroë was ravaged by the Abyssinians, and in the 6th century its place was taken by the Christian state of Nubia (*see* DONGOLA).

The Ethiopians appear to have derived their religion and civilization from the Egyptians. The royal inscriptions are written in the hieroglyphic character and the Egyptian language. About the time of Ergamenes, a vernacular came to be employed in inscriptions written in a special alphabet of 23 signs in parallel hieroglyphic and cursive forms. The cursive is to be read from right to left, the hieroglyphic, contrary to the Egyptian method, in the direction in which the figures face. It is clear that the forms and values of the signs are largely based on Egyptian writing; but decipherment has not been attained, nor can it be stated to what group the language should be assigned (F. Ll. Griffith in MacIver's *Areika*, 1909, and later researches).

BIBLIOGRAPHY.—Notices in Greek authors are collected by P. Paulitschke, *Die geographische Erforschung des afrikanischen Continents* (Vienna, 1880). *See* also J. H. Breasted, "The Monuments of Sudanese Nubia," in *American Journal of Semitic Languages* (Oct. 1908), and the work of E. W. Budge. A description of the chief ruins and the results of Dr. D. R. MacIver's researches in northern Nubia, begun in 1907, will be found under SUDAN: *History*.

ETHIOPIC LITERATURE. The employment of the Geez or Ethiopic language for literary purposes appears to have begun no long time before the introduction of Christianity into Abyssinia, and its pagan period is represented by two Axumite inscriptions (published by D. H. Müller in J. T. Bent's *Sacred City of the Ethiopians*, 1893), and an inscription at Matara (published by C. C. Rossini, *Rendiconti Accad. Lincei*, 1896). As a literary language it survived its use as a vernacular, but it is unknown at what time it ceased to be the latter. In Sir W. Cornwallis Harris's *Highlands of Aethiopia* (1844) there is a list of rather more than 100 works extant in Ethiopic; subsequent research has chiefly brought to light fresh copies of the same works, but it has contributed some fresh titles. A conspectus of all the mss. known to exist in Europe (over 1,200 in number) was published by C. C. Rossini in 1899 (*Rendiconti Accad. Lincei*, ser. v. vol. viii.); of these the largest collection is that in the British Museum, but others of various sizes are to be found in the chief libraries of Europe. R. E. Littmann (in the *Zeitschrift für Assyriologie*, xv. and xvi.) describes two collections at Jerusalem, one of which contains 283 mss.; and Rossini (*Rendiconti*, 1904) a collection of 35 mss. belonging to the Catholic mission at Cheren. Other collections exist in Abyssinia, and many mss. are in private hands. In 1893 besides portions of the Bible some 40 Ethiopic books had been printed in Europe (enumerated in L. Goldschmidt's *Bibliotheca Aethiopica*), but many more have since been published.

Influence of the Bible.—Geez literature is ordinarily divided into two periods, of which the first dates from the establishment of Christianity in the 5th century, and ends somewhere in the 7th; the second from the re-establishment of the Salomonic dynasty in 1268, continuing to the present time. It consists chiefly of translations, made in the first period from Greek, in the second from Arabic. It has no authors of the first or even of the second rank. Its character as a sacred and literary language is due to its translation of the Bible, which is made to contain 81 books, 46 of the Old Testament, and 35 of the New.

The mss. of the Biblical books vary very much, and none of them can claim any great antiquity; the oldest ms. in the language is said to be one of the Octateuch (Paris Y), which claims to have been written in the time of Yekūnō Amlak; but its editor, J. Oscar Boyd, Princeton, 1909–1911, seems to throw doubt on this date. The oldest extant ms. of the four Books of Kings appears to be one in the Museo Borgiano, presented by King Amda Sion (1314) to the Virgin Mary in Jerusalem (described by N. Roupp, *Zeitschrift für Assyriologie*, vol. xvi. 296–342). An examination of ten chapters of St. Matthew by L. Hackspill (*ibid.* vol. xi.) led to the result that the Ethiopic version of the Gospels was made about A.D. 500, from a Syro-occidental text, and that this original translation is represented by Cod. Paris. Aeth. 32; whereas most mss. and all printed editions contain a text influenced by the Alexandrian Vulgate, and show traces of Arabic. Rossini (*ibid.* x. 232) has made it probable that the Abba Salāmā, whom the native tradition identifies with Frumentius, evangelist of Abyssinia, to whom the translation of the Bible was ascribed, was in reality a Metropolitan of the early 14th century, who revised the corrupt text then current. Of the ancient translation the latest book is said to be Ecclesiasticus, translated in the year 678. The New Testament has been published repeatedly (first in Rome, 1548–49; some letters about its publication were edited by I. Guidi in the *Archivio della Soc. Rom. di Storia Patria*, 1886), and C. F. A. Dillmann edited a critical text of most of the Old

Testament and Apocrypha, but did not live to complete it.

Other translations thought to belong to the first period are the *Sher'ata Makhbār*, ascribed to S. Pachomius; the *Kerilos*, a collection of homilies and tracts, beginning with Cyril of Alexandria *De recta fide;* and the *Physiologus*, a fanciful work on Natural History (edited by F. Hommel, Leipzig, 1877).

Abyssinian History.—Of the works belonging to the second period much the most important are those which deal with Abyssinian history. The earliest part of the Axum chronicle preserved is that recording the wars of Amda Sion (1314–44) against the Muslims; it is doubtful, however, whether even this exists in its original form, as some scholars think; according to its editor (J. Perruchon in the *Journ. Asiat.* for 1889) it is preserved in a recension of the time of King Zar'a Ya'kūb. Under King Lebna Dengel (1508–40) the annals of his four predecessors, Zar'a Ya'kūb, Baeda Maryam, Eskender and Na'od (1434–1508) were drawn up; those of the first two were published by J. Perruchon (Paris, 1893); in the *Journ. Asiat.* for 1894 the same scholar published a further fragment of the history of Baeda Maryam, written by the tutor to the king's children, and the history of Eskender, Amda Sion II. and Na'od as compiled in Lebna Dengel's time. The history of Lebna Dengel was published by the same scholar (*Journ. Semit.* i. 274) and Rossini (*Rendiconti*, 1894, v. p. 617); that of his successor Claudius (1540–59) by Conzelmann (Paris, 1895); that of his successor Minas (1559–63) by F. M. E. Pereira Lisbon, 1888); those of the three following kings, Sharsa Dengel, Zā Dengel, and Ya'kūb, by Rossini (*Rendiconti*, 1893). The history of the next king Sysenius (1606–32) by Abba Meherka Dengel and Tekla Shelase was edited by Pereira (Lisbon, 1892); the chronicles of Joannes I., Iyasu I. and Bakaffa (1682–1730) by I. Guidi, with a French translation (Paris, 1903–05); all are contemporary, and the names of the chroniclers of the last two kings are recorded. Besides these we have the partly fabulous chronicle of Lalibela (of uncertain date, but before the Salomonian dynasty was restored), edited by Perruchon (Paris, 1892); and a brief chronicle of Abyssinia, drawn up in the reign of Iyasu II. (1729–53), embodying materials abridged, but often unaltered, was published by R. Basset, in the *Journ. Asiat.* for 1882, and has since formed the basis for Abyssinian history.

The Ethiopic Renaissance.—The remaining literature of the second period is thought to begin somewhat earlier than these chronicles. To the time of King Yekūnō Amlāk (1268–83) the historical romance called *Kebra Nagaset* (Glory of Kings) is assigned by its editor, C. Bezold (Bavarian Academy, 1904); other scholars gave it a somewhat later date. To the time of Yagbea Sion (*ob.* 1294) belongs the *Vision of the Prophet Habakkuk in Kartasā,* as also the works of Abba Salāmā, regarded as the founder of the Ethiopic renaissance, one of whose sermons is preserved in a Cheren ms. With his name are connected the *Acts of the Passion*, the *Service for the Dead* and the translation of Philexius, *i.e.*, Philoxenus. King Zar'a Ya'kūb composed or had composed for him as many as seven books; the most important of these is the *Book of Light* (*Mashafa Berhān*), paraphrased as *Kirchenordnung*, by Dillmann, who gave an analysis of its contents (*Über die Regierung des Königs Zar'a Ya'kob*, Berl. Acad., 1884). He also organized the compilation of the *Miracles of the Virgin Mary*, one of the most popular of Ethiopic books; a magnificent edition was printed by E. W. Budge in the Meux collection (London, 1900). In the same reign the Arabic chronicle of al-Makīn was translated into Geez. Under Lebna Dengel (*ob.* 1540), besides the above-mentioned collection of chronicles, we hear of the translation from the Arabic of the history and martyrdom of St. George, the Commentary of J. Chrysostom on the Epistle to the Hebrews, and the ascetic works of J. Saba called *Aragāwi manfasāwi*. Under Claudius (1540–59) Maba Sion is said to have translated from the Arabic *The Faith of the Fathers*, a vast compilation, including the *Didascalia Apostolorum* (edited by Platt, London, 1834), and the *Creed of Jacob Baradaeus* (published by Cornill, *ZDMG.* xxx. 417–466), and to the same reign belong the *Book of Extreme Unction* (*Mashafa Kandīl*), and the religious romance *Barlaam et Joasaph* also paraphrased from the Arabic (partly edited by A. Zotenberg in *Notices et Extraits*, vol. xxviii.). The *Confession of Faith* of King Claudius has been repeatedly printed. The reign of Sharsa Dengel (*ob.* 1595) was marked by many literary monuments, such as the religious and controversial compilation called *Mazmura Chrestos*, and the translation, by a certain Salik, of the religious encyclopaedia (*Mashafa Hāwī*) of the monk Nikon; an Arab merchant from Yemen, who took on conversion the name Anbākōm (Habakkuk), translated a number of books from the Arabic. Under Ya'kūb (*ob.* 1605) the valuable chronicle of John of Nikiou was translated from Arabic (edited by A. Zotenberg with French translation in *Notices et extraits*, vol. xxiv.). Under John, about 1687, the *Spiritual Medicine* of Michael, bishop of Adtrib and Malig, was translated. The literature that is not accurately dated consists largely of liturgies, prayers and hymns; Ethiopic poetry is chiefly, if not entirely, represented by the last of these, the most popular work of the kind being an ode in praise of the Virgin, called *Weddase Maryam* (edited by K. Fries, Leipzig, 1892). Various hymn-books bear the names *Degua*, *Zemmare* and *Mawas'et* (Antiphones); there is also a biblical history in verse called *Mashafa Madbal* or *Mestira Zamān.* Homilies also exist in large numbers, both original and translated, sometimes after the Arabic fashion in rhymed prose. Hagiology is naturally an important department in Ethiopic literature. Many texts containing lives of individual saints have been issued. Such are those of Maba Sion and Gabra Chrestos, edited by Budge in the Meux collection (London, 1899); the Acts of S. Mercurius, of which a fragment was edited by Rossini (Rome, 1904); the unique ms. of the original, one of the most extensive works in the Geez language, was burned by thieves who set fire to the editor's house. The same scholar began a series of *Vitae Sanctorum antiquiorum*, while *Monumenta Aethiopiae hagiologica* and *Vitae Sanctorum indigenarum* have been edited by B. Turaiev (Leipzig and St. Petersburg, 1902, and Rome, 1905). Other lives have been edited by Pereira, Guidi, etc. Similar in historical value to these works is the *History of the Exploits of Alexander*, of which various recensions have been edited by Budge (London, 1895). *See* further ALEXANDER THE GREAT.

Law and Philosophy.—Of Law the outstanding monument is the *Fatha Nagaset* (Judgment of Kings), of which an official edition was issued by I. Guidi (Rome, 1899), with an Italian translation; it is a version probably made in the early 16th century of the Arabic code of Ibn 'Assal, of the 12th century, whose work, being meant for Christians living under Muslim rule, was not altogether suitable for an independent Christian kingdom; yet the need for such a code made it popular and authoritative in Abyssinia. The translator was not quite equal to his task, and the Brit. Mus. ms. 800 exhibits an attempt to correct it.

Science can scarcely be said to exist in Geez literature, unless a medical treatise, of which the British Museum possesses a copy, comes under this head. Philosophy is mainly represented by mystical commentaries on Scripture, such as the *Book of the Mystery of Heaven and Earth*, by Ba-Hailu Michael, probably of the 15th century, edited by Perruchon and Guidi (Paris, 1903). There is, however, a translation of the *Book of the Wise Philosophers*, made by Michael, son of Abba Michael, consisting of various aphorisms; specimens have been edited by Dillmann in his Chrestomathy, and J. Cornill (Leipzig, 1876). There is also a translation of *Secundus the Silent*, edited by Bachmann (Berlin, 1888). Far more interesting than these is the treatise of Zar'a Ya'kūb of Axum, composed in the year 1660 (edited by Littmann, 1904), which contains an effort to evolve rules of life according to nature. Epistolography is represented by the diplomatic correspondence of some of the kings with the Portuguese and Spanish courts; some documents of this sort have been edited by C. Beccari, *Documenti inediti per la storia d' Etiopia* (1903); lexicography, by the vocabulary called *Sawāsew.* The first Ethiopic book printed was the Psalter (Rome, 1513), by John Potken of Cologne, the first European who studied the language.

See Basset, *Etudes sur l'histoire de l'Ethiopie* (1882); C. C. Rossini, "Note per la storia letteraria Abissina," in *Rendiconti della R. Accad. dei Lincei* (1899); Fumagalli, *Bibliografia Etiopica* (1893); Eno Littmann, *Geschichte der äthiopischen Litteratur* (Leipzig, 1907); catalogues of various libraries, especially British Museum (Wright), Paris (Zotenberg), Oxford and Berlin (Dillmann), Frankfurt (Gold-

schmidt). Plates illustrating Ethiopic palaeography are to be found in Wright's catalogue; an account of the illustrations in Ethiopic mss. is given by Budge in his *Life of Maba Sion;* and a collection of inscriptions in the church of St. Stefano dei Mori, in Rome, by Gallina in the *Archivio della Soc. Rom. di Storia Patria* (1888).

(D. S. MA.; X.)

ETHNOGRAPHICAL AND ANTHROPOLOGICAL SOCIETIES. The *Congrès International d'Anthropologie et d'Archéologie Préhistoriques* held its first meeting at Neuchâtel in 1866; it issued its first publication, *Comptes rendus* (1866, etc.). The *Royal Anthropological Institute of Great Britain and Ireland* was founded in 1871 upon the *Ethnological Society* (1843), which published a *Journal* (1848–56) and *Transactions* (1859–69) and the *Anthropological Society* (1863), which issued *Memoirs* (1863–69) and the *Anthropological Review* (1864–70). The *Institute* brings out a *Journal* (1871), *Man,* a monthly, etc. INDIA: Bombay, *Anthrop. Soc.* (1886), *Journal.*

ETHNOID SINUS: *see* OLFACTORY SYSTEM; EAR, NOSE AND THROAT, DISEASES OF THE.

ETHNOLOGY and **ETHNOGRAPHY,** primarily sciences which deal with man as a racial unit, and with the distribution over the earth of racial units. They include a comparative study of the physical characters of the races of mankind and also a comparative study and classification of peoples based upon cultural conditions and characteristics.

The article RACES OF MANKIND deals with the nature and distribution of the main races as now defined by anthropologists.

The word "ethnology" is used with a somewhat vague meaning for any ethnological study based on data of this general nature. "Ethnography" is conveniently restricted to the scientific mapping out of different racial regions, and exhibits the vital connection of social with geographical phenomena. (*See* ANTHROPOLOGY and the series of articles referred to therein.)

ETHYL, in chemistry, the alkyl (aliphatic hydrocarbon) radical C_2H_5. (*See* CHEMISTRY, ORGANIC: *Aliphatic Division.*) The hydride of ethyl is better known as ethane; the alcohol C_2H_5OH is the ethyl alcohol of commerce (spirit of wine) (*see* ALCOHOL); and the oxide $(C_2H_5)_2O$ is ordinary ether (*q.v.*).

Ethyl is a colloquial trade name for lead tetraethyl (*see* ORGANO-METALLIC COMPOUNDS), a liquid introduced in small amount into motor spirit in order to prevent "knocking." (*See* INTERNAL COMBUSTION ENGINES.)

ETHYL CHLORIDE, prepared from hydrogen chloride and ethyl alcohol, is a gas at room temperature but is stored and sold under pressure in glass bottles fitted with trigger-controlled spray nozzles, as a colourless, mobile liquid with a characteristic ethereal smell, and sweet, burning taste, which boils at 12·5° C and has the formula C_2H_5Cl. The vapour burns with a green flame. Chloryl and kelene are trade names. Anestile is a mixture of ethyl and methyl chlorides. Somnoform is composed of the two chlorides with ethyl bromide.

Uses.—It is used (*a*) as a local anaesthetic for small incisions, tooth extractions and needle punctures, by spraying it on the surface of the skin or mucous membrane in a fine stream with particular care that the end of the spray stream is focused upon the point to be frozen. Its rapid evaporation causes local freezing (−35° C can be obtained).

(*b*) As a general anaesthetic, it is usually given in doses of 3–5 cu.cm. in a closed inhaler. As regards safety it is probably intermediate between nitrous oxide and ether. Short administrations produce an anaesthesia similar in type to that of nitrous oxide with an equally rapid loss of consciousness, a quick recovery and slight after-effects.

Ethyl chloride like chloroform as a general anaesthetic has its popularity chiefly in Europe. On the whole it seems to be more dangerous than ether and nitrous oxide but less so than chloroform. It does not produce the muscular relaxation effected by chloroform, which is desirable especially in protracted operations. Moreover, it is inflammable. Ethyl chloride has been recommended for anaesthesia of short duration in the belief that it was less dangerous than and as satisfactory as nitrous oxide.

Longer administrations approximate more to the ether type of anaesthesia, ethyl chloride being, like chloroform and ether and unlike gas, a lipoid solvent. Its effect on the circulatory and respiratory systems is slightly stimulating, causing flushing of the face, acceleration of the pulse rate by 10–20 beats per minute, and a rise in systolic blood pressure of 10 to 20 millimetres, together with deeper and more rapid breathing. (*See* ANAESTHESIA.)

(*c*) It is also used in mechanical refrigeration (*see* REFRIGERATION AND ICE MAKING) in place of ammonia or sulphur dioxide, because of its relatively low pressure and non-toxic qualities.

ETHYLENE, also known as olefiant gas or ethene, is found in coal gas and is the first representative, C_2H_4, or $H_2C{:}CH_2$, of the series of olefine hydrocarbons. It is a colourless gas of somewhat sweetish taste, slightly soluble in water, but more so in alcohol and ether. It can be liquefied at −1·1° C, under a pressure of 42½ atmos. It solidifies at −181° C and melts at −169° C; it boils at −105° C (L. P. Cailletet), or −102° to −103° C (K. Olszewski). Its critical temperature is 13° C. It is usually prepared by heating a mixture of ethyl alcohol and sulphuric acid. G. S. Newth (1901) obtained a purer product by dropping

ethyl alcohol into syrupy phosphoric acid (sp. gr. 1·75) warmed to 200° C, subsequently raising the temperature to 220° C. A variant of this process is employed in the manufacture of ethylene when alcohol vapour is passed at 300° C over charcoal impregnated with phosphoric acid. It is also manufactured by passing alcohol vapour over heated alumina at 360° C. Scientific interest attaches to its preparation from (1) ethyl bromide and alcoholic potash; (2) the electrolysis of a concentrated solution of potassium succinate.

Ethylene burns with a bright luminous flame (*see* FLAME), and forms a very explosive mixture with oxygen. On heating it decomposes, giving, among other products, carbon, methane and acetylene (M. Berthelot, 1866). Being an unsaturated hydrocarbon, it is capable of forming addition products, *e.g.*, it combines with hydrogen in the presence of platinum black or heated nickel to form ethane, with chlorine and bromine to yield the corresponding ethylene dihalides, with sulphuric acid at 160–170° C to form ethyl sulphuric acid, $C_2H_5 \cdot HSO_4$, and with aqueous hypochlorous acid to form glycol chlorhydrin, $Cl \cdot CH_2 \cdot CH_2OH$. It combines with sulphur trioxide and with halogen hydrides. Dilute potassium permanganate solution oxidizes it to ethylene glycol, $HO \cdot CH_2 \cdot CH_2 \cdot OH$, whilst fuming nitric acid converts it into oxalic acid. Several compounds of ethylene and metallic chlorides are known; with ferric chloride and platinous chloride in hydrochloric acid it gives $C_2H_4 \cdot FeCl_3 \cdot 2H_2O$ and $C_2H_4 \cdot PtCl_2$ respectively. When inhaled ethylene is a general anaesthetic (Luckhardt and Carter, 1923). It is given with 7–12% of oxygen, but caution is necessary because this mixture of gases is explosive. To deepen the ethylene anaesthesia, ether may be added.

ÉTIENNE, CHARLES GUILLAUME (1778–1845), French dramatist and miscellaneous writer, was born near Saint Dizier, Haute-Marne, on Jan. 5, 1778. He wrote for the Paris theatres for 20 years from 1799 onwards, but he is remembered chiefly as the author of *Les Deux Gendres*, represented at the Théâtre Français on Aug. 11, 1810, which brought its author a seat in the Academy, and an accusation of plagiarism from a play in the imperial library, entitled *Conaxa, ou les gendres dupés*. The bitterness of the attacks made on him was no doubt in part due to his position as editor-in-chief of the official *Journal de l'Empire*. The patriotic opera *L'Oriflamme* and his lyric masterpiece *Joconde* date from 1814. As secretary to Maret, duc de Bassano, Etienne had accompanied Napoleon throughout his campaigns in Italy, Germany, Austria and Poland. During these journeys he produced one of his best pieces, *Brueys et Palaprat* (1807). During the Restoration Étienne was an active member of the Opposition.

His *Oeuvres* (6 vols., 1846–53) contain a notice of the author by L. Thiessé.

ETIQUETTE, a term for ceremonial usage, the rules of behaviour observed in society, more particularly the formal rules of ceremony to be observed at court functions, etc.; the procedure, especially with regard to precedence and promotions in an organized body or society. Professions, such as the law or medicine, observe a code of etiquette, which the members must respect as protecting the dignity of the profession and preventing injury to its members. (*See* BUSINESS CODES.) The O.Fr. *estiquette* or *estiquet* meant a label, or "ticket," a meaning retained by the mod. Fr. *étiquette*. The ultimate origin is Teutonic, from *sticken*, to post up, stick, affix. For a summary guide to the various forms of social address, *see* FORMS OF ADDRESS.

ETNA, a borough of Allegheny county, Pa., U.S.A., 2m. N. of Pittsburgh, on the west bank of the Allegheny river. It is served by the Baltimore and Ohio, the Etna and Montrose and the Pennsylvania railways. The population was 6,341 in 1920, and was estimated locally at 7,509 in 1928. It is an important manufacturing suburb of Pittsburgh, producing iron, steel, brass, enamelled ware and various other commodities. The borough (at first called Steuart's Town) was incorporated in 1869. Its industrial history dates from 1820, when a small factory was built to make scythes and sickles. Natural gas was piped in from Butler county to serve as fuel for the early iron mills.

ETNA, an active volcano on the east coast of Sicily (Gr. Αἴτνη, from αἴθω, burn; Lat. *Aetna*), the summit of which is 18 m. N. by W. of Catana. Its height was ascertained to be 10,758 ft. in 1900, having decreased from 10,870 ft. in 1861. It is the highest volcano in Europe and the highest mountain in southern Italy. Its base is elliptical (31 m. by 19 m.) and covers 460 sq.m. The Torre del Filosofo, a building of Roman date, is only 1,188 ft. from the summit. In shape it is a truncated cone, with the great rift of the Valle del Bove, a huge sterile abyss 3 m. wide, on its east side. This latter is the original crater, the volcanic axis having shifted to the present summit crater. There are some 200 subsidiary cones, some of them over 3,000 ft. high, which have risen on lateral fissures that converge toward the central crater. The mountain is built up of three superimposed parts which correspond to three distinct zones of vegetation. The lowest "regione coltivata" extends up to 3,000 ft., has a gentle gradient, and is a great belt of volcanic products. It is densely populated and of luxuriant fertility (vine, olive, fruit, vegetables, corn, etc.), and often yields five harvests a year. On it are the towns Catana, Nicolosi and Acireale. The middle zone "regione boscosa" has a gradient of 1 in 5 and is no longer rich in oak plantations as at one time but now grows abundant pine, genista broom, chestnut, beech and ferns. The highest and central zone "regione deserta" is a desolate region of lava flows and volcanic ash, almost destitute of vegetation. There is a narrow zone of sub-Alpine shrubs, but no true Alpine flora. In the last 2,000 ft. five phanerogamous species only are to be found, the first three of which are peculiar to the mountain: *Senecio Etnensis, Anthemis Etnensis, Robertsia taraxacoides, Tanacetum vulgare* and *Astragalus siculus*. No trace of animal life is to be found in this zone; for the greater part of the year it is covered with snow, but by the end of summer this has almost all melted, except for that preserved in the covered pits for use in Catania and elsewhere. The ascent is best undertaken in summer or autumn, 7 to 8 hours being required from Nicolosi. Thucydides mentions eruptions in the 8th and 5th centuries B.C. The activity comprises three periods:—prehistoric, before 700 B.C., early historic, from 700 B.C. until the 16th century and the historic period from that time. During the historic period eruptions have taken place at intervals of approximately 6 years.

Geologically, Etna is a large volcanic cone which stands in a great Pliocene subsidence bay of the Ionian Sea. It is in contact with Tertiary sedimentary rocks in the north-west. Here occur grey Eocene and yellow and red Miocene sandstones and limestones with Pliocene marine marl and plastic clay. These latter entirely compose the floor of the platform upon which the volcanic pile has been built up. Near the coast ancient lava flows overlie Pleistocene conglomerates and gravels, thus proving that the subaerial activity did not begin until middle Quaternary times. The volcanic rocks consist of crystalline and vitreous lavas and tuffs, essentially basaltic in composition, largely porphyritic and wholly non-leucitic. Other types are augite and phonolitic andesites and labradorite rock. The andesites were the earliest erupted rocks. Basic plagioclase felspar and augite are the most common minerals, olivine being very subordinate or missing altogether. The constancy of composition indicates derivation from a remarkably uniform magma. At Acireale the lava has assumed the prismatic or columnar form in a striking manner; at the rock of Aci it is in parts spheroidal. The Grotte des Chèvres has been regarded as an enormous gas-bubble in the lava. The remarkable stability of the mountain appears to be due to the innumerable dykes which penetrate the lava flows and tuff beds in all directions and thus bind the whole mass together.

From the earliest times the mountain has naturally been the subject of legends. The Greeks believed it to be either the mountain with which Zeus had crushed the giant Typhon (so Pindar, *Pyth.* i. 34 *seq.*; Aeschylus, *Prometheus Vinctus*, 351 *seq.*; Strabo xiii. p. 626), or Enceladus (Virgil, *Georg.* i. 471; Oppian, *Cyn.* i. 273), or the workshop of Hephaestus and the Cyclopes (Cic. *De divin.* ii. 19; *cf.* Lucil., *Aetna*, 41 *seq.*, Solin, 11). Several Roman writers, on the other hand, attempted to explain the phenomena which it presented by natural causes (*e.g.*, Lucretius vi. 639 *seq.*; Lucilius, *Aetna*, 511 *seq.*). Ascents of the mountain were not infrequent in those days—one was made by Hadrian.

In Nov. 1928 grave consternation was caused by the renewed

activity of Etna. The Messina-Catania railway line was blocked by the streams of lava 100 ft. wide descending from the crater at an average speed of 20 ft. a minute. On Nov. 7 the lava reached the sea. The town of Mascati was completely wiped out and the village of Nunziata almost entirely destroyed. The loss was estimated at £2,000,000.

See Sartorius von Waltershausen, *Atlas des Ätna* (Leipzig, 1880); E. Chaix, *Carta Volcanologica e topographica dell' Etna* (showing lava streams up to 1892); G. de Lorenzo, *L'Etna* (Bergamo, 1907); C. S. du Riche Preller, *Italian Mountain Geology*, Part III. (1923).

ETON, a town of Buckinghamshire, England, on the Thames, opposite Windsor. Pop. 3,301. It is famous for its college, the largest of the ancient English public schools. The "King's College of Our Lady of Eton beside Windsor" was founded by Henry VI. in 1440–41 and endowed mainly from the revenues of the alien priories suppressed by Henry V. The founder followed the model established by William of Wykeham in his foundations of Winchester and New College, Oxford. The original foundation at Eton consisted of a provost, 10 priests, 4 clerks, 6 choristers, a schoolmaster, 25 poor and indigent scholars, and the same number of poor men or bedesmen. In 1443, however, Henry increased the number of scholars to 70. The bedesmen who soon disappeared were reduced. A connection was then established, and has been maintained since, though in a modified form, between Eton and Henry's foundation of King's College, Cambridge. One of the king's chief advisers was William of Waynflete, who had been bishop of Winchester and was appointed provost of Eton in 1443. The statutes in their final form provided for the establishment of *commensales* or commoners, distinct from the scholars; and these under the name of "oppidans" now form the principal body of the boys. The college survived the unsettled period at the close of Henry's reign; while Edward IV. curtailed its possessions, and was only just prevented from amalgamating it with the ecclesiastical foundation of St. George, Windsor Castle. The teaching embraces classical and modern subjects; but until the first half of the 19th century the normal course of instruction remained almost wholly classical.

The present constitution of the college dates from an act of 1868. Under the statute, last modified in 1904, the foundation consists of a provost, appointed by the Crown, and a body of fellows, comprising the provost of King's college, Cambridge, a vice-provost, representatives nominated respectively by the universities of Oxford and Cambridge, the Royal society, the lord chief justice and the masters of the school, the remaining four being co-opted. The scholarships are open to all boys who are British subjects between 12 and 15 years of age. Twenty-four foundation scholarships at King's college, Cambridge, are reserved for Etonians; and there are several scholarships and exhibitions tenable at Oxford or Cambridge, or either university.

The college buildings were founded in 1441 and occupied in part by 1443, but the whole original structure was not completed till 50 years later. The older buildings consist of two quadrangles. The outer quadrangle, or school-yard, is enclosed by the chapel, upper and lower schools and the original scholars' dormitory ("long chamber"), now transformed. It has in its centre a bronze statue of the royal founder. The buildings enclosing the inner or lesser quadrangle contain the residence of the officials, the library, hall and various offices. The chapel represents only the choir of the church which the founder originally intended to build; but as this was not completed Waynflete added an ante-chapel. The chapel contains some monuments of provosts and at the west end of the ante-chapel is a fine statue of the founder, by John Bacon. A chapel on the north side commemorates Etonians who fell in the World War. A chantry contains the tomb of Roger Lupton (provost (1503–35), whose most notable monument is the fine tower between the schoolyard and the cloisters. The space enclosed by two buttresses on the north side of the chapel, at the point where steps ascend to the north door, is the model of the peculiar form of court for the game of fives which takes its name from Eton, with its "buttress" (represented by the projecting balustrade), the ledges round the walls, and the step dividing the floor into two levels. From the foundation of the college the chapel was used as the parish church until 1854, and not until 1875, after the alteration of the ancient constitution had secularized the foundation, was the parish of Eton created into a separate vicarage. The chapel does not accommodate the whole school; and a new chapel, from the designs of Sir Arthur Blomfield, is used by the lower school. This contains some admirable modern tapestries, glass and woodwork. The library contains many manuscripts (notably an Oriental collection) and rare books; and there is also a library for the use of the boys. The college has far outgrown its ancient buildings, and new buildings, besides the lower chapel, include the new schools, with an observatory, a chemical laboratory, science schools, and museum and boarding-houses. In 1908 King Edward VII. opened a range of buildings erected in honour of the old Etonians who served in the South African War. The buildings include a school hall with a fine organ, a domed octagonal library, and a museum of antiquities.

The principal annual celebration is held on June 4, the birthday of King George III. Speeches in Upper School, and a procession of boats are regular features of the day. In rowing Eton occupies a unique position among the public schools, and a large proportion of the oarsmen in the University boat-race have been *alumni* of the school. Another annual celebration is the contest between collegers and oppidans at a peculiar form of football known as the wall game, from the fact that it is played against a wall bordering the college playing-field. This game takes place on St. Andrew's Day, Nov. 30. The field game of football commonly played at Eton has also peculiar rules. The leading cricket matches are those between Eton and Winchester (played alternately at the two schools) and Eton and Harrow (at Lord's ground, London). A singular custom termed the *Montem*, first mentioned in 1561, was observed here triennially on Whit-Tuesday. The last celebration took place in 1844. It consisted of a procession of the boys in a kind of military order, with flags and music, headed by their "captain," to a mound called Salt Hill, near the Bath road, where they levied contributions or "salt" from spectators. The average number of pupils exceeds 1,100.

See Sir H. C. Maxwell Lyte, *History of Eton College from 1440 to 1910* (1911); Willis and Clark, *Architectural History of Cambridge*, etc. (1856. vol. i.); A. C. Benson, *Fasti Etonenses* (1899); L. Cust, *History of Eton College* (1899); R. A. Austen Leigh, *Guide to the Buildings of Eton College* (1921). (M. R. J.)

ETOWAH MOUND, THE, on Etowah river, 3 m. S.E. of Cartersville, Barlow county, Georgia, is a quadrilateral truncated pyramid, 61 ft. high, with a broad roadway ascending the south side to within 18 or 20 ft. of the top, and formerly provided with steps made of crossbeams embedded in the earth. The base measures 380 by 330 ft., and the top 170 by 176 ft.; the area of the base is nearly three acres, and of the top not quite seven-tenths of an acre. The solid contents of the mound, including the roadway, are estimated at 4,300,000 cu. ft. The Etowah mound has been identified with the Guaxule of Hernando de Soto, but this is questioned; it is one of the sites from which have come copper plates with repoussé figures suggesting Mexican provenience. The name is from *Itawá* (corrupted to "High-tower"), of unknown meaning and probably not Cherokee, given to two or more former Cherokee towns in Georgia.

ÉTRETAT, a watering-place of France, in the department of Seine-Inférieure, on the coast of the English Channel, 16½ m. N. by E. of Havre by road. Pop. (1926) 1,687. It stands between curiously worn chalk cliffs at the mouth of a valley, the stream of which runs underground for some distance to emerge on the beach. A Roman road and aqueduct and other Roman and Gallic remains have been discovered. The church of Notre-Dame is a fine example of Romanesque architecture of the 11th and 13th centuries. Fishing is carried on.

ETRURIA, an ancient district of Italy, the extent of which varied considerably, and, especially in the earliest periods, is very difficult to define (*see* section *Language*). The name is the Latin equivalent of the Greek Τυρρηνία or Τυρσηνία, which is used by Latin writers also in the forms *Tyrrhenia, Tyrrhenii;* the Romans also spoke of Tusci, whence the modern Tuscany (*q.v.*). In early times the district appears to have included the whole of North Italy from the Tiber to the Alps, but by the end of the 5th cen-

tury B.C. it was considerably diminished, and about the year 100 B.C. its boundaries were the Arnus (Arno), the Apennines and the Tiber. In the division of Italy by Augustus it formed the seventh *regio* and extended as far north as the river Macra.

History.—The authentic history of Etruria consists mainly in the story of its relations with Carthage, Greece and Rome. At some period unknown, prior to the 6th century, the Etrurians extended their power not only northwards over, probably, Mantua, Felsina and Melpum, but also southwards into Latium and Campania. The chronology of this expansion is unknown, nor do we know for certain the names of the cities which constituted the two leagues of twelve founded in the conquered districts on the analogy of the original league in Etruria proper.

In the early history of Rome the Etruscans play a prominent part. According to tradition they were the third of the constituent elements which went to form the city of Rome. The tradition is still an unsolved problem. It is practically certain, however, that there is no foundation for the ancient theory (*cf.* Prop. iv. [v.] 1, 31) that the third Roman tribe, known as Luceres, represented an Etruscan element of the population, and it is held by many authorities that the tradition of the Tarquin kings of Rome represents the temporary domination of Etruscan lords, who extended their conquests some time before 600 B.C. over Latium and Campania. This theory is corroborated by the fact that during the reigns of the Tarquin kings Rome appears as the mistress of a district including part of Etruria, several cities in Latium, and the whole of Campania, whereas our earliest picture of republican Rome is that of a small state in the midst of enemies. For this problem *see* ROME: *History*, section The Monarchy.

After the expulsion of the Tarquins the chief events in Etruscan history are the vain attempts of the Etruscans to re-establish themselves in Rome under Lars Porsena of Clusium, the defeat of Octavius Mamilius, son-in-law of Tarquinius Superbus, at Lake Regillus, and the treaty with Carthage. This last event shows that the Etruscan power was formidable, and that by means of their fleet the Etruscans controlled the commerce of the Tyrrhenian sea. By this treaty Corsica was assigned to the Etruscans while Carthage obtained Sardinia. Soon after this decay set in. In 474 B.C. the Etruscan fleet was destroyed by Hiero I. (*q.v.*) of Syracuse, Etruria Circumpadana was occupied by the Gauls, the Campanian cities by the Samnites, who took Capua (*see* CAMPANIA) in 423, and in 396, after a ten years' siege, Veii fell to the Romans. The battle of the Vadimonian Lake (309 B.C.) finally extinguished Etruscan independence. For the archaeology, art and religion of Etruria, *see* ETRUSCANS.

ETRUSCAN LANGUAGE. From the days of Dionysius of Halicarnassus, who declared that Etruscan was like no other language, to the present time, many attempts of various kinds, none completely successful, have been made to decipher the monuments still extant of this difficult language. Scholars now base their labours on the internal study of the language and employ the principle of combination and chronology to elucidate less known details by established details, gaining some definite results.

Material.—There survive (1) a certain number of words preserved by Latin and Greek authors (*see* Skutsch *bibl.*) such as *aisar*=*deos* (Etr. *ais*=deity), *ister*=actor, whence the Latin *histrio;* (2) about 8,500 inscriptions from the 7th century B.C. to the time of Augustus, nearly all of which have been collected in the *Corpus*, 90% of which are only proper names. The longest inscriptions are (*a*) the tablet of S. Maria di Capua (300 words) and the Cippus Perusianus (120); (3) A liturgical text of about 1,500 words written in the wrappings of the famous mummy of the Museum of Agram (Zagreb). External evidence dates this in the 2nd century B.C. It should be remembered that Etruscan was used after the date of this material and that according to Ammian (xxiii., 5, 10) the soothsayers used it as a liturgical language up to the date of the 4th century A.D.

Alphabet.—The alphabet closely resembled the Central and Greek alphabets of the Boeotian type specially and shows that Etruscan only possessed surd occlusives which tended to become spirants, as is shown by the variations in the records both of pure Etruscan words as *sec* and *seχ*, *lart* and *larθ*, *acsi* and *aχsi* and in words borrowed from the Greek such as *σπυριδα* (acc.) and *sporta*, *θριάμβος* and *triumpus*, so that to the influence of an Etruscan substratum, scholars have attributed the change from *c* to *h* in the speech of Florence, *e.g.*, *hasa* for *casa*, *poho* for *poco*. In Etruscan *f* weakened to *h* as *flastntru* and *hastntru*, *cafatia* and *cahatia*. Then the short interior vowels are lately reduced and often disappear, perhaps with an initial accent. *Menelaos* is written *Menle; Heracles*, *hercle; Achilleus*, *aχle; Clutaimestra*, *Clutmsta*. The Latin loan word *pronopes* becomes *prumθs*.

Structure.—Etruscan-Latin bilingual texts are rare, very short, do not always agree and are of very little help. The few definite features are as follow. In names borrowed from Greek, Etruscan distinguished gender by the terminating *e* for the masculine (*hercle*, *aχle*, etc.) and *ai*, *ei* for the feminine (*Elinai*, *-ei*, Heeleene, *φersipnai*, *-ei*, Persephone). In certain true Etruscan names the feminine is sometimes in *i*, *larθ*, fem. *larθi*, or in *ia*, *irnθ*, fem. *arnθia* or in *θζ*, *lautni* (freed man), fem. *lautniθa*. These variations may depend on the form of the root as in the case-endings. The nominative is the normal form of the root. The genitive is in *s* or *ś* with roots ending in a vowel (*seθre* and *seθres*), in *uś*, with roots ending in a consonant as *velθur*, *velθurus: θinχvil*, and *θanχviluś*. The most characteristic genitive is in *l* and indicates filiation, thus *arnθ*, *arnθcl*, son of *Arruns*. It may even be added to another genitive, to form a genitive or filiative of the second degree, as *velθur* gives *velθuruś* son of Velθur and *velθuruśla*, the son of the son of *Velθur*. The dative is sometimes in *ś* identical with the genitive as *Mi* (this) *θuplθaś* (to Thupeltha) *alpan* (as a gift) *turce* (he gave). The more usual form is in *śi* as *auleśi* (to Aulus) *meteliś* (Metellus) *ve*(*lus*) (of Vel) *Vesial* (of Vesia) *clenśi* (to the son) = To Aulus Metellus son of Vel and Vesia. The word for son is *clan* in the nominative, *clenś*, genitive and *clenśi*, dative. It is not known whether an accusative existed. The plural is in *ar:clan*=son; *clenar*=sons; *ais*=deity; *aisar*=deities.

Verb.—As to the verb, all that is definite is that the 3rd person singular of the perfect tense was in *ce: amce*=has been; *turce*=has given; *tece*=has raised; *lupuce*=has lived. Sometimes this ending is missing as *avils* xxxvi *lupu*=lived 35 years.

Numerals.—The order of the numbers on the dice found at Toscanella is open to question but it is regarded as probable that *maχ*=1; *zal*=2; *θu*=3; *huθ*=4; *ci*=5 and *śa*=6. It is known that 7, 8, 9 are *cezp*, *semφ*, *muv*, but their exact identification is not settled. Tens were formed by adding *-alχ;* thus, from *ci*=5, we get *cealχ*, *celχ*=50, and from *cezp* we get *cezpalχ*.

The number of words definitely known by bilingual inscriptions or as contained in concordances is so limited that it is still impossible to decipher accurately any part of a lengthy text such as that on the Zagreb rolls. The following words are known: *usil*=sun; *tiv*=moon; *alpan*=offering; *fleres*=statue; *zamaθiman*=golden brooch; *hinθial*=soul; *lautn*=family; *ril*, *avil*=age or year; *ati*=mother; *puia*=wife; *sec*, *seχ*=daughter; *θura*=brother; *nefts*=grandson—borrowed from Latin *nepos*, *mi*=this; *-m*, *-c*=and. The syntax is known only through very simple phrases such as: *pumpui larθi puia larθal clevsinas aveleśla seχ sentinal θanχvilus*=Larthi Pompeia, wife of Larth Clevsinas son of Aulus, daughter of Tanaquilla Sentinei; or *trepi θanχvil vipenas arnθal arnθialiśla puia*=Tanaquilla Trebia, wife of Arruns Vipena, son of Arruns.

Origins.—Opinion is still divided as to the Lydian origin of the Etruscans as recounted by Herodotus. Some regard them as indigenous in Italy on the ground that, apart from archaeological evidence, it is impossible, on the linguistic material available, to identify the affinities of Etruscan with any other form of speech. Others point to the use by Lydian and that in the Caucasian languages of the genitive in *l*, to the plural in *ar* found in Caucasian speech, to the copula *-c* found in Lydian (*see* ASIANIC LANGUAGES), to the presence in Lycian and Etruscan of an important number of nominal suffixes, and to the discovery in Lemnos of an inscription in a language closely allied to Etruscan. F. de Saussure (Recueil, p. 573) assigned as Asianic origin to the ending *ηνος* in *Τυρσηνοι* and V. Thomsen ranged Etruscan with

the Caucasian group.

These views are not necessarily contradictory. It may be surmised that the first migration of Etruscans (*Tu[r]sci*) moved from Asia Minor at an early date to Greece (Pelasgians) and were soon separated from the other branch (*Turseni*) of the same stock who remained in Asia Minor whence they spread much later. This hypothesis explains the existence and the paucity of contacts between Etruscan and Asianic languages. Until a lengthy bilingual text has been discovered, we depend on the internal study of the language, a slow, difficult but relatively sure method. In 1928 Prof. Alfredo Trombetti read before the International Congress of Languages at The Hague his discoveries in connection with the dicipherment of Etruscan inscriptions.

See the *Reports* of the congress and *Anthropos*, parts 1–2 (1928).

(E. BEN.)

ETRUSCANS, THE. The problem of the origin and connection of the Etruscans has assumed a wholly new aspect owing to the progress of archaeological research. The expectation that the key to the language would some day be found has been disappointed, and it has become evident that the limited character and style of the inscriptions forbids any hope that they will ever yield historical information of any value. On the other hand the steady progress of archaeological exploration and comparative study has revealed the chronological sequence of the various sites and their relative antiquity, so that it is now possible to say when and where the Etruscans first appeared upon Italian soil and by what stages their power was extended. Several periods of antiquity are now distinguished in the complex whole long termed indiscriminately "Etruscan art." It is also possible to show the point of cleavage between the work of the indigenous Italians and that of their foreign overlords. Etruscan life has been studied in all its varied phases from the 8th century B.C. to the 1st, and the capital problem of origins has been approximately solved.

Literary Evidence.—Literary evidence in ancient writers is extraordinarily slight in amount and inferior in quality. The Etruscans produced no native historian. True, the emperor Claudius composed a so-called history in some 20 books, but it is unlikely that posterity has suffered any loss from the disappearance of this voluminous and, no doubt, curious work. In the sphere of ritual and religion Claudius may have gathered together a quantity of curious matter from the lost "Acherontian books" of the priests, and this would have had no little antiquarian interest, especially for students of folk-lore and ceremony. But as regards history in its proper sense it is highly probable that Claudius never possessed the material, even if he had been gifted with the ability to write anything that would meet modern requirements. Similarly, the great authors of the Augustan period are almost worthless for this purpose. Virgil is frankly and honestly writing a romance; his Mezentius of Caere, if not a complete invention, is at best the romantic embellishment of a figure of doubtful authenticity. Livy is the historian of Roman victories, the Etruscans are of no value or interest to him except as cannon-fodder. For the chronicle of the wars with Veii he may be fairly trustworthy and probably possessed a certain amount of real information, but he could know little of the brilliant periods of Etruscan pride and supremacy in the 6th and 7th centuries B.C. References to the Etruscans are found in a number of other classical writers, from the serious historian, Polybius, an excellent authority for the late period with which he deals, down to poets of the decadence like Statius and Silius Italicus. But apart from the military and political events recorded by Polybius and Livy all the statements of classical authors put together convey hardly any information. In regard to the question of Etruscan origins every poet and every prose writer except Dionysius of Halicarnassus accepts as a matter of course the story of their migration from Lydia as given by Herodotus, who tells how in the reign of Atys, son of Manes, there was great scarcity of food in all Lydia which lasted 18 years. "At last their king divided the people into two portions and made them draw lots so that the one part should remain and the other leave the country; he himself was to be the head of those who drew the lot to remain there, and his son, whose name was Tyrrhenus, of those who departed. Then one part of them, having drawn the lot, left the country, and came down to Smyrna and built ships, whereon they set all their goods that could be carried on shipboard and sailed away to seek a livelihood and a country; till at last, after sojourning with many nations in turn, they came to the Ombrici, where they founded cities and have dwelt ever since. They no longer called themselves Lydians but Tyrrhenians, after the name of the king's son who had led them thither." (Loeb, trans. I., p. 125.) But the apparent unanimity of all the Greek and Latin writers is of no value as evidence, because all are drawing on a single source. Dionysius of Halicarnassus, who composed his *Roman Archaeology* in the time of Augustus, was at least as much interested in destroying the credit of his predecessors as in ascertaining the truth. He unearthed a 5th century Lydian author, one Xanthus, who might be set up as a rival to Herodotus, not in the original but only in the 3rd century *rechauffé*, which one ancient critic at least judged to be a forgery. This document, Dionysius informs us, makes no mention of the emigration of Lydians under Tyrrhenus, and therefore he argues that the story told by Herodotus must be an invention. But it is obvious that there might be a score of reasons for the omission, even if the history of Xanthus were complete, so that the argument cannot be taken very seriously.

Dionysius states that the Etruscans were original, autochthonous, inhabitants of Italy. Here he is more deserving of attention; the theory is by no means impossible and has been revived by good modern archaeologists. But the insuperable difficulty is the language. Had the Etruscans been really indigenous, they would surely have spoken a language related in some degree to one or other of the dialects which were still being used in the days of Augustus by the descendants of the really native Italians, that is to say, of the peoples of the Stone and Bronze ages. And yet, as Dionysius himself says, their language was something entirely unique and peculiar; a statement fully endorsed by modern philologists. Dionysius' theory may contain a slight amount of truth. For the conclusion to which archaeologists are now beginning to rally is that whereas the Etruscans themselves were immigrants, a very small ruling hierarchy, the backbone of their power was in the native races which they subdued: their citizens, agriculturists, workmen, soldiers, artisans were almost all Italians.

Archaeological Evidence.—As to the place from which these foreign overlords came and the route by which they entered the country there has been a complete revolution of opinion. Niebuhr thought he had discovered traces of the Etruscan language still lingering in the common speech of some of the peoples in the Eastern Alps. From this he jumped to the conclusion that these were survivals from the beginning of the Iron age, and that the inhabitants of the Rhaetian Alps were descendants of an invading army which must be identified with an army of the first conquering Etruscans. This argument ignores the well known existence of quite late Etruscan colonies north of the Po, and Livy's statement that a certain number of Etruscans took refuge in the Alps from the invading Gauls of the 4th century and went wild in their savage surroundings; which would be a perfectly good explanation of any such phenomena as Niebuhr has noted. Archaeology has shown that no Etruscan settlements were made on the north side of the Apennines before 500 B.C., the very date that is to say when the Tarquins were being expelled from Rome and the Etruscans had been in full possession of a great part of Italy for several centuries.

So much progress has now been made in the relative dating of the various sites that it may be said without hesitation that all the earliest settlements were on the sea coast. Vetulonia and Tarquinii are the very earliest; Caere is almost equally ancient; Volaterrae (Volterra), though not actually on the coast, is within easy reach of the sea, and was the capital of a region which had its ports at Luna and Populonia. The comparatively late foundation of inland cities like Perusia (Perugia) and Arretium (Arezzo) is beyond all question. The only contradictory case that might seem to arise is that of Clusium, the modern Chiusi. But there is really nothing in Chiusi which obliges us to date it back to the first years of the conquest. On the contrary, the pre-Etruscan

SPECIMENS OF ETRUSCAN GOLDSMITH WORK

1. Fibula or brooch from Vetulonia; 2. Fibula from the Tomba del Littore; 3. Necklace from the Tumulo della Pietrera; in the Museum of Florence; 4. Pendant from the Tumulo della Pietrera; in the Museum of Florence; 5. Fibula from Poggio alla Guardia; 6. Pin from southern Etruria, Tomba del Littore; in the Museum of Florence; 7. Fibula from Vetulonia

city of Camars, which stood there seems to have retained its native Italian character with extraordinary tenacity, and was probably not Etruscanized till the middle of the 7th century, so that even the city of Lars Porsenna is no exception to the rule that every inland Etruscan site is of later foundation; the original settlements are all along the line of the Tuscan Maremma. Geographical reasoning therefore points clearly to an invasion, or perhaps rather a colonization, by successive bands of emigrants who landed on the most prominent points of the sea coast of Tuscany. From the character of their earlier remains the date of the first permanent settlement may be placed at the end of the 9th century.

That the Etruscans were orientals or semi-orientals is proved by the whole character of their earliest art, and by many details of their religion and worship. It is an art which shows close contact with Mesopotamia, Syria and Cyprus on the one side and with Egypt on the other. The deities and mythological figures on Etruscan gold-work and jewellery of the 7th century are evidently the heroes and deities of Asiatic mythology. Masks of entirely Assyrian character decorate the handsome bronze cauldrons; Assyrian monarchs at the chase are shown on silver bowls of the same period, while other bowls and ivories figure purely Egyptian scenes, and one is inscribed with the name of a Phoenician owner. Much of this work was doubtless imported, but the very fact that the trade of these centuries was exclusively with the East is something wholly new in the history of Italy, which had never before traded with the Aegean, not even in the great days of Mycenae. And if much of the finer work was imported, a great deal was certainly produced in Italy, where the arrival of the Etruscans was signalized by the immediate rise of wholly new schools of design in metal-work and jewellery, the development of which can be traced as early as the 8th century. In the sphere of ritual and religion there are many details which are taken direct from Mesopotamia, and the whole feeling and atmosphere are purely oriental. The most striking identities are in the practices of divination and augury; for the custom of divining from the livers of sheep or the flight of birds is purely Chaldaean (*see* DIVINATION). There are models of clay livers from Mesopotamia inscribed in cuneiform which precisely resemble the bronze model of a liver found at Piacenza, divided into compartments each of which is labelled in Etruscan with the name of its presiding divinity.

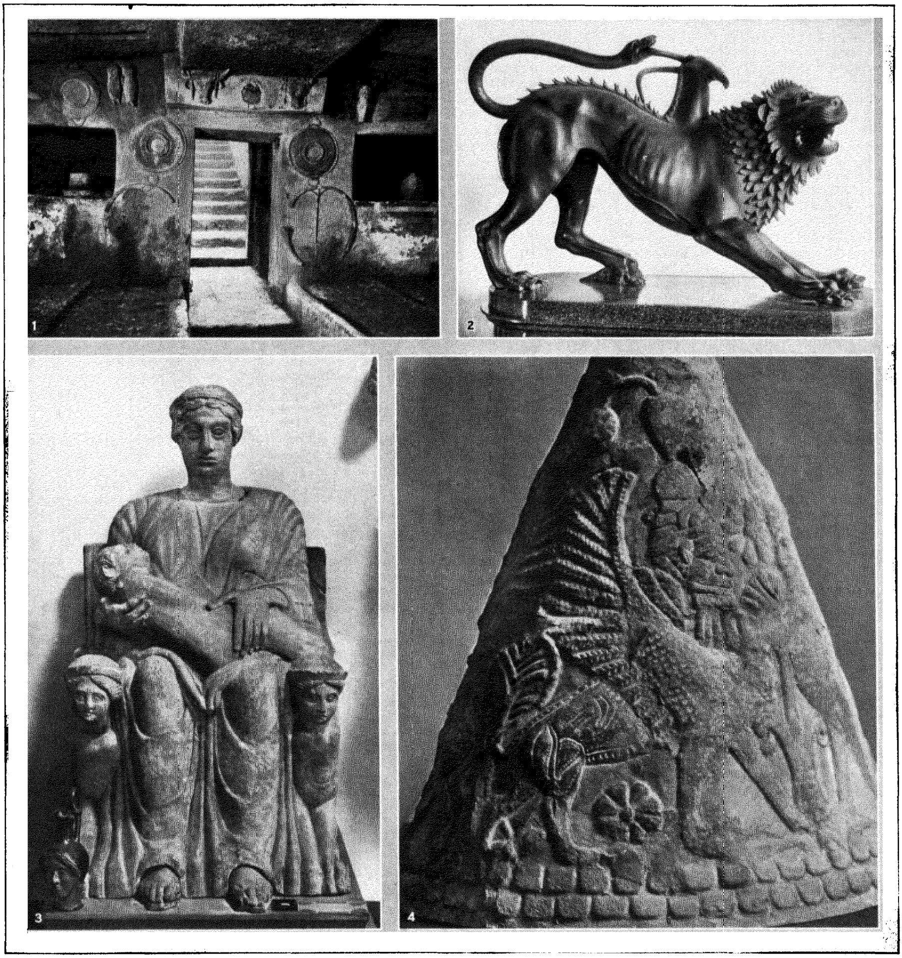
On the capital questions, therefore, of the origin of the Etruscans, and the date and place of their arrival in Italy, archaeology is ready with a clear answer. They came from some part of Asia Minor, whether or not it was Lydia, as Herodotus asserts, is immaterial. Their original home must be sought somewhere between the Hellespont and Syria. In its broad lines the tradition given by Herodotus is borne out by archaeological research.

The Etruscan nation was very loosely compacted, even in the days of its greatest power. It always retained the character of an aggregate of clans, probably resulting from the circumstances of the conquest by small isolated bands. Though these clans refrained from internecine war, they were quite unwilling to band together for any common cause except under the stress of some extraordinary emergency. Except in Macaulay's *Lays*, it may be doubted if Etruria ever acted as a whole. Each city seems to have considered itself free to conduct its own policy, and to make war or peace with little or no consideration for the interests of the rest. Thus history records few more pathetic instances of political blindness than the apathy of the great Etrurian cities in the long wars between Veii and Rome, which allowed the Romans, though actually the weaker, to swallow all Etruria piecemeal. A confederacy of 12 cities existed in the 6th century, which held its annual meetings at the shrine of Voltumna above the Lacus Volsiniensis (Lake of Bolsena). It is not necessary, however, to follow Livy in representing these meetings as something like a conference of premiers. Judging from the smallness of the results, it seems more likely that the confederation confined itself principally to affairs of religion. No complete list exists of the 12 members in early days, the pedestal of the statue of Claudius is too late in date to be good authority, even if complete.

From partial references, however, in Livy, Dionysius and Diodorus, it is possible to make up a list which, eked out by the names given on this pedestal, would include Vetulonia, Tarquinii, Vulci, Caere, Volaterrae (Volterra), Clusium (Chiusi), Arretium (Arezzo), Rusellae, Cortona, Perusia (Perugia), Populonia, to which must undoubtedly be added Veii.

EXAMINATION OF CITY SITES

Of several of the most ancient and important cities in this list a good deal is known as the result of excavation. Vetulonia, Tarquinii and Caere have been extensively explored; valuable though limited excavations have been made at Vulci; Populonia is periodically examined as often as the removal of the refuse of smelting lays bare an area of ancient tombs; Chiusi has much to teach, even though its riches have been wantonly plundered



PHOTOGRAPHS, ALINARI

ETRUSCAN ARCHAEOLOGICAL REMAINS

1. Interior of the Tomb of the Stuccoes, or Grotta Bella, Cervetri (ancient *Caere*). The Etruscans in their construction of tombs often reproduced the interior features of contemporary houses and by carving the soft rock or tufa imitated the wooden beams and other architectural details. The arrangement and contents of the tombs, which included furniture, gold and silver objects, utensils of daily life, clothing and ornaments, as well as wall-paintings and sculpture, furnish the best records yet discovered of the life and artistic achievements of the Etruscans
2. Bronze Chimaera from Arezzo, of the 5th century B.C., found in 1553. Two of the legs had been broken, and were restored by Benvenuto Cellini. This piece is not derived from the Greek style, but is of pure Etruscan origin. Archaeological Museum, Florence
3. The *Mater Matuta*, a funerary statue in *pietra fetida*, of the 5th century B.C., found near Chianciano. Archaeological Museum, Florence
4. The base of a large drinking bowl from an archaic tomb at Praeneste. The decoration, like that of much of the Etruscan work unmistakably Oriental in character, strongly resembles Assyrian designs. Museum of the Villa Giulia, Rome

and scattered; Volterra has preserved its late walls and numbers of late sarcophagi; Arezzo, Perugia and Cortona are each celebrated for individual works of art found sporadically. Only Rusellae is a quite virgin site awaiting the spade of the explorer.

Vetulonia.—Here was one of the earliest, if not the very earliest, of the settlements made by the Etruscans when they landed on the west coast of Italy, and here it has been possible to trace their graves from the very first generation. The commanding site on the hill of Vetulonia had previously been occupied for a long period by the native Italians, and by the unbroken consecutive sequence of the cemeteries it is possible to detect the precise moment when the new foreign influence appears. Native Italian burials begin on this site at a stage which, at Bologna, is well known as the very opening of the Villanovan period, and continue through the whole of the First and Second Benacci stages. Towards the end of the Second Benacci at Vetulonia new types of tombs begin to appear, together with whole series of foreign imports previously unknown, such as gold, silver, amber and Egyptian scarabs. This is the moment of the first effective colonization by the Etruscans. On the Bolognese analogy the date should be very near 800 B.C.

The Etruscan tombs at Vetulonia continue through the 8th century and down to the middle of the 7th; after which they disappear, at any rate in the area which has hitherto been explored. The picture which is given is therefore a complete picture of the life of the invaders for a little over 100 years after their first settlement. It may be studied in all its details in the very rich collection in the museum at Florence. This material shows a certain seriation, a progress from simpler to more complicated designs and technique, especially in the gold-work, which exhibits all the steps in the development of a local school. The finest tombs belong to the latter half of the 8th and, perhaps, the beginning of the 7th century, especially the Tomba del Duce, which is particularly valuable for the many points of similarity between its contents and those of the Regolini-Gulassi and similar tombs at Caere and Praeneste; of the bronze-work the finest examples are bronze cauldrons, resembling those dedicated at Olympia; the best jewellery is from the Lictor's tomb, Le Migliarine and La Pietrera. A bucchero pottery cup from the Tomba del Duce bears an Etruscan inscription of 46 letters, almost, if not quite, the earliest epigraphical document in the language. A silver cup from the same tomb, as well as the silver casing of the ossuary, were finely ornamented with oriental designs.

Caere.—This town is famous for the Regolini-Galassi tomb found there nearly a century ago, the contents of which form the most valuable part of the small Vatican museum of Etruscan antiquities. The principal cemetery, however, lies on the other side of the ancient town at the place known as Banditaccia. Most of the great tumuli have long been known and are well described in Dennis. They contain usually two or three gallery tombs apiece, of which the most important have been named from their most striking features as the tombs "Dei Pilostri," "Del Triclinio," "Dei Tarquinii" and "Dei Sarcofagi." A large mausoleum of this kind was used for a long period, so that the dates range from the beginning of the 7th down to the middle of the 4th century B.C. The character of the great vases and tomb-furniture is best illustrated in the Campana collection in the Louvre, which was principally formed from the pillage of such tombs as these. Internally, the structure of a gallery tomb reproduces the features of the contemporary house, varying in the number and arrangement of its rooms, but imitating the architectural details of the wooden beams by carving the soft tufo rock.

Since Dennis wrote his account the general appearance of Banditaccia, as Canina names it, has been very much changed by recent excavations, the results of which remain unpublished. With its carefully laid out streets and quarters allocated to each class of burial it now suggests a Pompeii of the dead. The numerous antiquities found in these later excavations are exhibited in the Museo di Villa Giulia at Rome. The Regolini-Galassi is probably the best known of a group of four tombs, of which the others were found respectively at Praeneste and at Cumae. All four belong precisely to the same generation and contain objects of identical or very similar character. The Regolini-Galassi tomb has no architectural interest. It is merely a narrow passage divided by a partition into two chambers, with a recess on each side of the fore chamber. The passage is roofed by overlapping blocks, without any attempt to apply the principle of the arch, which seems to have been still unknown. No information has been preserved as to the style of the building in the two Praeneste tombs, known respectively as the Barberini and the Bernardini. In the fore chamber at Caere there was buried a warrior, laid on a bed of bronze, which was perfectly preserved. In the chamber behind this were all the ornaments and jewellery of a woman, whose body had fallen into dust but whose bridal trousseau lay in place precisely as she had worn it. On the low wall between the two chambers stood great bronze cauldrons; along the roof had been nailed bowls and dishes of silver and bronze, and on the walls around the warrior had been nailed bronze shields and bundles of arrows. Near him stood a four-wheeled chariot, and in the right hand niche was a two-wheeled chariot. An inventory of the contents of the Regolini-Galassi tomb would occupy many pages. The gold-work alone would stock a large jeweller's shop; it includes huge fibulae, bracelets, plaques and chains, executed principally in the technique either of granulation or of filigree. There are silver cups, silver jugs and engraved silver bowls.

More of these bowls were found in the Bernardini and Barberini tombs, in which also there were a number of carved ivories. All these belong to a well-marked school of oriental work, the centre of which seems to have been in or near Cyprus. Bowls with precisely similar scenes of oriental date and mythology have been unearthed on several sites in Cyprus, indeed the Cesnola collection of Cypriote antiquities in the Metropolitan Museum of New York contains one which must have been actually made by the same hand as a bowl from the Bernardini tomb. In the less known Artiaco tomb of Cumae were bronze basins, a silver ossuary, and gold ornaments of which some are almost precise duplicates of those in the Regolini-Galassi. The sporadic occurrence of an Etruscan burial so far south is curious and enigmatic.

This group of four tombs, so rich that their contents are sufficient to characterize the work and civilization of an entire period, must be placed in the 7th century; the question is to what point in the century they should be assigned. The tendency of more recent examination is to bring these nearer to 700 B.C., perhaps precisely 670 B.C., which makes the approximation of types to Vetulonia more consistent and intelligible.

Tarquinii.—This site, now known as Corneto, shares with Vetulonia the claim to be the earliest of all the settlements. It derives its name from the family of Tarquin, or in its native form Tarchon, so well known in the legendary history of early Rome. Excavations on this site have revealed four extensive cemeteries of the pre-Etruscan Villanovans, beginning in the First Benacci period and coming down to a stage which overlaps, as at Vetulonia, the Etruscan occupation. An exact synchronism between the latest Villanovan at Corneto and the earliest Etruscan at Vetulonia is furnished by silver filigree bracelets of identical pattern found on both sites. This corroborates the sequence dating established for the arrival of the Etruscans, whose effective occupation of their earliest posts must fall in the middle of the Second Benacci period. It is a dating which tallies with the end of the 9th or beginning of the 8th century, to which we are also driven by internal criticism of the pottery, gold-work and other contents of the Etruscan graves themselves.

Two tombs at Corneto are of great importance for chronological dating, viz., the Warrior's tomb and the Bocchoris tomb. The former contains a fine set of bronze vessels and gold ornaments which closely resemble examples found in the great circle-graves at Vetulonia, as well as an interesting set of geometric pottery. The Warrior's tomb is certainly not later than the 8th century, but some critics would place it at 800 B.C., or even earlier, while others bring it down almost to 700 B.C. Far more closely dated than the Warrior's tomb is one which is named the Bocchoris tomb, from a vase of Egyptian faience inscribed with the name of Bokenranf, known to Greek writers as Bocchoris, who reigned

in Egypt for only six years (734–728 B.C.). Genuinely Egyptian objects are extraordinarily rare in Italy, and a vase so closely dated by an inscription is absolutely unique. As the Egyptian vase fixes the date of the tomb to within a generation, it is important to note a piece in the Regolini-Galassi, which is a distinct argument in favour of bringing the date of the whole Regolini-Galassi group up to almost 700 B.C.

The very important frescoed tombs of Corneto are dealt with below in the paragraph on painting.

Vulci.—The remains of the cemeteries of this important city are very extensive, but in spite of the wholesale pillaging of tombs in the middle of the 19th century, only a small amount of scientific work has been done there. The results of Gsell's excavations, unfortunately limited to a small proportion of the whole area, have not yet found their way into a public museum, though published in a carefully written volume. Dennis gives an admirable account of the site, to which there is little more to add except the information given by Gsell. Pillage from Vulci has found its way sporadically into several museums, especially outside Italy. The Campana collection of the Louvre contains a certain amount of material, but the best individual group which has been preserved is the Polledrara tomb, sometimes known by the ridiculous nickname of the Grotto of Isis, now in the British Museum. This is remarkable for its Egyptian objects, carved ostrich-eggs, faience bottles and a scarab of Psammetichus I. As this king reigned from 663 to 609 B.C., the scarab gives only an approximate dating. The pottery, however, is of a very closely differentiated class which assigns the Polledrara tomb quite definitely to within a few years of 600 B.C. All the bronze work in it has the finesse and delicacy of a distinctly later stage than the Regolini-Galassi.

The cemeteries at Vulci covered an immense area and comprised a great variety of tomb-forms of all dates. Tumuli, of which the so-called Cucumella is the best example, large chambers such as the Francois tomb and the Campanari, and plain trench graves have produced a quantity of archaeological material, especially pottery, which is now scattered in many places.

Volaterrae (Volterra).—This was undoubtedly a city of very ancient foundation and of great importance, but owing to the curious local conditions very few traces of the oldest period survive. The battered stone effigy of a warrior, inscribed with the name of Larthi Atharnies, now in the Florence museum, is almost the only evidence that Volterra is as ancient as Tarquinii and Vetulonia. Periodical landslips have carried away so much of the land that it may be doubted whether the more ancient cemeteries will ever be discovered. By a curious irony, however, the latest and most debased period of Etruscan art is represented in the museum by a series of sarcophagi of the 2nd and 3rd centuries, made of the local alabaster carved with bloodthirsty travesties of scenes from Greek story. The walls and gateways are, with those of Perugia, among the finest examples of late-Etruscan architecture.

Clusium (Chiusi).—This is one of the most individual and peculiar of all the Etruscan cities in respect of its art and customs. Probably this may be explained by the long survival of a native tradition which showed extraordinary tenacity. Chiusi was not fully Etruscanized in feeling until well on in the 7th century. It is peculiar in retaining the custom of cremation as its sole burial rite, a habit which gave rise to the curious art of its so-called canopics, ossuaries of pottery moulded in the semblance of human masks which, though often grotesque, sometimes arrive at a considerable degree of realism in portraiture. This was the genesis of a school of sculpture and modelling which has never been sufficiently studied. At Palermo is a considerable collection of Chiusan bas-relief which it is hoped may be eventually transferred to Florence. Apart from this the only place in which Chiusan antiquities can be reviewed as a whole is the museum of Florence, though isolated specimens from this region, which was pitilessly sacked all through the 19th century, may be found in many European collections, and the local museum at Chiusi itself contains some very fine examples. At Florence the finest tomb groups are those of Poggio alla Sala and Pania, from the latter of which came a magnificently carved ivory situla of the 7th century. An isolated specimen of great interest is also the silver bucket engraved with a procession of foot soldiers and inscribed with the name Plicasnas, which forms a link with the art of southern Etruria. Chiusi was the centre of the finest production of the black pottery known as Etruscan bucchero.

Populonia.—This place owes its importance entirely to its proximity to the island of Elba, here only 6 m. away from the mainland. It is likely that even before the Etruscans arrived the iron-mines of Elba had been discovered and exploited by the Villanovans, of whose graves a considerable number have been found here. The ore was brought over from the island to the mainland to be smelted, and the masses of scoriae cover an immense area. As the smelting continued in Roman times the Etruscan cemetery was buried under the débris, and it is only by degrees that the tombs are brought to light as the rubbish is removed by a company which has found it worth while to re-work the refuse. The most interesting are chambers surrounded by circular tumuli of stone blocks. Populonia is likely to prove one of the most instructive sites as the long sequence of its occupation is revealed; the material in the museum at Florence, the best of which is of the 6th and 5th centuries, already includes a fine chariot, painted vases and gold jewellery.

ART AND RELIGION

Etruscan Art.—It is an error to deny the existence of an independent Etruscan art or to treat it as a mere offshoot and dependent of the Greek. Until the end of the 7th century Greek influence on Etruria was very slight, and in the nature of things it could not be very important before that time. But for at least 150 years before this the Etruscans had lived in an art-loving atmosphere and their tombs of the 7th, if not of the 8th century, which may be less certain, had been filled with exquisite objects in bronze and gold and silver and ivory. The contents of these tombs show no trace of Greek inspiration. The art which they mirror is derived from the Near East, from centres which were in touch with Egypt, Assyria, Syria and Cyprus. All Etruscan trade at this period was with Phoenicians, Cypriotes and others who were swarming round crucibles of Egypto-Assyrian civilization situated somewhere in the Levant. Then the Etruscans themselves were very fine craftsmen, and although they imported freely, yet they probably came over with a considerable heritage of artistic tradition from their original homes, which they certainly developed to a great extent on their own lines in Italy.

In the latter half of the 7th century Corinthian influence began to be felt in Etruria, and with the beginning of the 6th appear the painted Attic vases. From this moment Greek influence is certainly predominant, and in many branches, especially of the minor arts, Etruscans of the 6th century and afterwards were principally interpreters and imitators of Greek fashions. In the major arts of architecture and sculpture, however, the Etruscans remained to a great extent independent. Temples and houses and tombs were constructed on original plans which were quite un-Hellenic, even if some of the external ornament was often borrowed. Above all, in their statuary the Etruscans never lost the original genius which inspired the earliest work of Vulca and continued down to the 3rd century. Many copies of Greek masterpieces were executed in Etruscan studios, but side by side with these were such pure products of native inspiration as the Chimaera of Arezzo, the Wolf of the Capitol and the Orator from Lake Trasimene. The statue of the Orator discloses the parentage of Roman portrait-sculpture; from this it is clear that the Romans derived much of their peculiar gift from their Etruscan inheritance, or perhaps from actual Etruscan masters living amongst them. The finest extant piece of Etruscan sculpture of the early time is the Apollo of Veii, dating from the last years of the 6th century, but probably by no means the earliest product of a school of which the other works have perished. If it has affinities with Ionian sculpture, it is none the less a perfectly independent creation.

In many Etruscan tombs the walls are covered with frescoes, the finest of which are those at Corneto and in the neighbourhood of Chiusi. With the exception of those in the Grotta Campana

ETRUSCAN SCULPTURE AND BRONZE

1. Sarcophagus, with figures of a noble and his wife, dating from the end of the 6th or the beginning of the 5th century B.C. From Cervetri (*Caere*). Museum of the Villa Giulia, Rome. 2. Funerary group in *pietra fetida*, 5th century B.C., from Chianciano. Archaeological Museum, Florence. 3. Archaic head of a warrior, on a funerary pillar, found at Orvieto (Volsinii). Archaeological Museum, Florence. 4. The Apollo of Veii, a statue of painted terra cotta dating from the last years of the 6th century B.C. It was found in 1916, and is generally considered the finest example extant of early Etruscan sculpture. In the Villa Giulia, Rome. 5. Head of the Apollo of Veii. 6. Stone effigy of a warrior known as Larthi Atharnies, 8th century B.C., found at Volterra. Archaeological Museum, Florence. 7. Bronze cauldron on tripod, found in the Regolini-Galassi tomb, Cervetri. Etruscan Museum of the Vatican. 8. Figure of a warrior on primitive grave stone, found at Volterra. Archaeological Museum, Florence

at Veii, which are purely decorative and probably belong to the 7th century, none of these paintings is earlier than 600 B.C. Consequently they are so much affected by Greek style and subjects that their value is a good deal impaired as records of Etruscan civilization. Nevertheless there are a good many scenes from which valuable details may be gleaned as to customs and habits, especially in social life. The favourite scene is a funeral banquet, with all the preparations for it and the procession which preceded it. Probably the motive was simply to ensure by magic a repetition of the material pleasures enjoyed in this world. Chariot-races, dancing, wrestling, prize-fighting and athletic contests are depicted among the amusements. The style is closely in harmony with the contemporary vase painting of the time, so that in the first half of the 6th century Ionic fashions are dominant, while after this Attic vase painting, especially the severe red-figured style of 500 B.C. comes into play. In some tombs of the end of the 5th century Pythagoreanism begins to assert itself and to affect the representation with a mystic and gloomy atmosphere. The most characteristic of the paintings, however, are essentially gay and happy, without the slightest suggestion of melancholy, and with only slight references to the presence of the Genius of death.

It is from the tomb-paintings that the best idea may be obtained of the games and amusements to which the Etruscans, like the Lydians, were so much addicted. Horse-riding and chariot-races were much in vogue; wrestling and boxing-matches took place on every important occasion. And on every occasion, whether important or not, there was music. The favourite instrument was a double-pipe of the Phrygian kind but a syrinx was also used. The Romans credited the invention of more than one kind of horn or trumpet to the Etruscans, from whom they confessed to have borrowed the *lituus* and from whom they learned the use of the pipes and the flute.

Religion.—Of the religion it is not possible to make any satisfactory study in the absence of documents. The names of a certain number of deities are known, but little can be said of their functions or attributes. The existence of a celestial triad corresponding to the Roman Jupiter, Juno and Minerva is affirmed by late Roman writers, and the Etruscan equivalents of these names are known to be Tinia, Uni and Menrva. Corresponding to these there seems to have been a triad of infernal deities, perhaps Mantus, Mania and the equivalent of Demeter. Fufluns was the Etruscan equivalent of Bacchus, Sethlans of Vulcan, Turms of Mercury. Tiv was the deity of the moon, Thesan of the dawn, Catha of the sun. Several of these names, and others more difficult of identification, are given on the bronze laver of Piacenza. Besides these a very important deity was Voltumna, whom the Romans called Vertumnus; it was at his shrine that the annual meetings of the confederacy took place. In the underworld there were various demons, especially Charun and Tuchulcha.

The influence of Etruscan rite and ceremonial upon the Romans was very wide and deep. Not only did the latter borrow from Vetulonia the insignia of their magistrates, the curule chair and the fasces, the purple toga and the trumpets, but the rites with which they laid out a city were Etruscan and their processions and triumphs were on an Etruscan model. The augurs and haruspices were Etruscan and as late as the time of the emperor Julian the Etruscan soothsayers formed a part of every Roman army. In every department of their public life the debt of the Romans to their neighbours and sometime rulers is unmistakable.

Writing and the Alphabet.—The Etruscans used a form of alphabet which is a variant of one of the early Greek alphabets. It contains letters not used by the Campanian Greeks and represents an older inheritance of independent tradition. The first instances of its appearance are a little before 700 B.C., the inscribed statues of Avtiles Feluskes and Larthi Atharnies, as well as the bucchero cup from the tomb of the Prince at Vetulonia belong to the 8th century. A little later than 700 are the three versions of the alphabet, given respectively on an ivory tablet from Marsiliana, and two earthenware pots, found respectively at Veii and at Caere. Of literature in the proper sense there are no remains, and it is impossible to tell whether any existed, though it may be significant that the Latin writers never mention any. Religious books, however, were composed in the later periods and the outlines of an *Etrusca disciplina* were known to Cicero.

The Army and Navy. Conquests and Settlements.—Of the Etruscan army some idea may be formed from such representations as those on the situla of the Certosa found at Bologna. Cavalry must have been important and chariots are found in every large grave. But the foot soldiers were, doubtless, the backbone of the force. These were armed principally with either of two weapons, the spear or the axe, which was sometimes used not only for striking but for throwing. Javelins and arrows are also commonly found in the graves. Shields and helmets were of several designs, some adapted from the Greek, others borrowed from the eastern Alps. Swords, probably rare and much prized, were of various models, derived from Hallstatt and from Greece.

The Etruscan navy was extremely formidable and rendered them the scourge of the western Mediterranean for several centuries. It enabled them to defeat the Phocaeans, to conquer Corsica and Sardinia, and to hold their own against Carthaginians and Greeks down to 474 B.C., when their defeat at Cumae marked the beginning of a series of disasters from which they never recovered.

The Etruscan power had reached its height about 30 years before this, and it was in the last few years of the 6th century that a new experiment was made in the direction of empire-building. Colonies were sent to establish themselves north of the Apennines, to build up a new Etruria which should include the whole basin of the Po and extend to the shores of the Adriatic, but the Gauls swept away this newly annexed region. Livy's words must not be forced into a statement that there was ever an Etruscan empire stretching from the Alps to Messina, but nevertheless it must be recognized that the Etruscans were the creators of more than a third of ancient Italy. The limits of their permanent achievement, the territory in which their work lived on, even when their political power had been destroyed, might be defined by a line drawn from Milan to Chioggia meeting another line drawn from the mouth of the Po to the mouth of the Tiber. The peoples whom they administered, and by whom they were eventually assimilated, were principally those who have survived into modern days as the Tuscans and the Umbrians.

The Roman conquest of Etruria after centuries of fighting virtually concluded by the series of deadly duels with Veii was completed just before the Punic wars. Numerous Roman colonies were planted throughout the conquered territory, which eventually passed into the Roman empire as the 7th division of the administration devised by Augustus.

Bibliography.—Of the older books C. O. Muller's *Die Etrusker*, as revised by G. Deecke, will always be a standard, and *The Cities and Cemeteries of Etruria* by G. Dennis, now accessible in the "Everyman" series, is an imperishable classic. G. Martha's *Art étrusque*, once important, is no longer up to date. The best and most comprehensive of modern works are those of P. Ducati in Italian; his two small volumes entitled *Etruria Antica*, give a complete review of the entire subject and are accompanied by a full bibliography. Art is studied in a larger work by Ducati called *Arte Etrusca*. The special subject of painting is well treated by F. Weege, *Etruskische Malerei*, and briefly but clearly by F. Poulsen, *Etruscan Tomb Paintings*. Amongst detailed monographs of local excavations Falchi's *Vetulonia* and Gsell's *Fouilles de Vulci* are valuable; A. Minto's *Marsiliana d'Albegna* and *Populonia, la necropoli arcaica* are important to the specialist. The results of excavations for the period down to 650 B.C. are incorporated with a critical analysis in *Villanovans and Early Etruscans* by D. Randall-MacIver, and a small popular volume on *The Etruscans* by the same author reviews the entire subject. R. A. Fell's *Etruria and Rome* treats of the political and military history from a topographical standpoint. The wars between Rome and the Etruscans are adequately described in most of the standard histories. Articles by Körte, von Duhn and others are to be found in Pauly-Wissowa and in Ebert's *Real Lexikon der Vorgeschichte*.

(D. R.-M.)

ETTENHEIM, a town of Germany, in the republic of Baden, situated on the Ettenbach, under the western slope of the Black forest. Pop. (1925) 3,091. Founded in the 8th century by Eddo, bishop of Strassburg, Ettenheim remained attached to that see until 1802, when it passed to Baden. It has a mediaeval town hall,

and in the Roman Catholic Church lies the last prince bishop of Strassburg, d. 1803. Its industries include the manufacture of tobacco, and there is a considerable trade in wine and agricultural produce. The Benedictine abbey of Ettenheimmünster, founded in the 8th century and dissolved in 1803, occupied a site south of the town.

ETTINGSHAUSEN, CONSTANTIN, BARON VON (1826–1897), Austrian geologist and botanist, was born in Vienna on June 16, 1826. Professor of botany at Vienna and then at Graz, he carried out important researches on the Tertiary floras of various parts of Europe, and on the fossil floras of Australia and New Zealand. He died at Graz on Feb. 1, 1897.

ETTLINGEN, a town of Germany, in the republic of Baden, on the Alb and the railway Mannheim-Basel, 4½ m. S. of Karlsruhe. Pop. (1925) 9,435. The first notice of Ettlingen dates from the 8th century. It became a town in 1227 and was presented by the emperor Frederick II. to the margrave of Baden. Surrounded by old walls and ditches, it presents a mediaeval appearance. Among its most striking edifices are an old princely residence, with extensive grounds and the buildings of a former monastery. There are also many Roman remains, notable among them the "Neptune" sculpture, now embedded in the wall of the town-hall. Its chief manufactures are paper, explosives, spinning, weaving and machine building. Considerable trade is done in wine and fruit which are cultivated in the neighbourhood.

See Schwarz, *Geschichte der Stadt Ettlingen* (Karlsruhe, 1900).

ETTMÜLLER, ERNST MORITZ LUDWIG (1802–1877), German philologist, was born at Gersdorf near Löbau, in Saxony, on Oct. 5, 1802. He studied from 1823 to 1826 at the University of Leipzig. In 1830 he delivered at Jena, under the auspices of the university, a course of lectures on the old Norse poets. The rest of his life was spent at Zürich, where he taught first in the gymnasium and then in the university. He died at Zürich in April 1877. To the study of English Ettmüller contributed by an alliterative translation of Beowulf (1840), an Anglo-Saxon chrestomathy entitled *Engla and Seaxna scopas and boceras* (1850), and a well-known *Lexicon Anglo-Saxonicum* (1851), in which the explanations and comments are given in Latin. He edited a large number of High and Low German texts, and to the study of the Scandinavian literatures he contributed an edition of the *Völuspa* (1831), a translation of the *Lieder der Edda von den Nibelungen* (1837) and an old Norse reading book and vocabulary. He was also the author of a *Handbuch der deutschen Literaturgeschichte* (1847), which includes the treatment of the Anglo-Saxon, the Old Scandinavian and the Low German branches.

ETTRICK, a river and parish of Selkirkshire, Scotland. The river rises in Capel Fell, a hill in the extreme south-west of the shire, and flows north-east for 32 m. to its junction with the Tweed, its principal affluent being the Yarrow. In the parish of Ettrick was born James Hogg, the "Ettrick shepherd" (the site of the cottage being marked by a monument erected in 1898). About 2 m. below Ettrick church is Thirlestane Castle, the seat of Lord Napier and Ettrick, a descendant of the Napiers of Merchiston, and beside it is the ruin of the stronghold that belonged to John Scott of Thirlestane under James V. Two miles up Rankle Burn, a right-hand tributary, lies the site of Buccleuch, another stronghold of the Scotts, which gave them the titles of earl (1619) and duke (1663). Only a fragment remains of Tushielaw tower, occupying high ground opposite the confluence of the Rankle and the Ettrick. Lower down the dale is Deloraine, recalling one of the leading characters in *The Lay of the Last Minstrel.* Carterhaugh, a corruption of Carelhaugh, where Ettrick and Yarrow meet, was the scene of the ballad of "Young Tamlane."

ETTY, WILLIAM (1787–1849), British painter, was born at York on March 10, 1787, the son of a baker and confectioner. At the age of eleven and a half William was bound apprentice in the printing-office of the *Hull Packet.* He completed his term of seven years, and having in that period come by practice, at first surreptitious, though afterwards allowed by his master "in lawful hours," to know his own powers, he removed to London.

The kindness of an elder brother and a wealthy uncle, William Etty, himself an artist, stood him in good stead. He began by copying without instruction from nature, models, prints, etc., his first academy, as he himself says, being a plaster-cast shop in Cock Lane, Smithfield. Here he made a copy from an ancient cast of Cupid and Psyche, which was shown to Opie, and led to his entry in 1807 as student of the Academy, whose schools were at that time conducted in Somerset House. Among his fellow scholars were Wilkie, Haydon, Collins and Constable. In the summer of 1807 he was admitted to be a private pupil of Sir Thomas Lawrence. For some years after he quitted Sir Thomas's studio, even as late as 1816, the influence of his master was traceable. In 1811, after repeated rejections, his "Telemachus Rescuing Antiope" was hung in the Academy. For the next five years he persevered with quiet and constant energy, and he was even beginning to establish something like a name when in 1816 he resolved on a journey to Italy. In 1820 his "Coral-finders," exhibited at the Royal Academy, had a great success, more than equalled by that of "Cleopatra's Arrival in Cilicia," shown in the following year. In 1822 he again set out on a tour to Italy. Though Etty was impressed by the grand *chefs-d'oeuvre* of Raphael and Michelangelo at Rome, he always regarded Venice as the true home of art in Italy. His wonderful colouring in his paintings of the nude owes much to his close study of and admiration for the great Venetian masters.

Early in 1824 he returned home, and in that year he was made A.R.A. and in 1828 R.A. In the interval he had produced one of his greatest works, the "Combat (Woman interceding for the Vanquished)," and the first of the series of three pictures on the subject of Judith, both of which ultimately came into the possession of the Scottish Academy. Etty's career was from this time one of slow but uninterrupted success. During the next ten years of his life he was a constant attendant at the Academy life school, where he used to work regularly with the students, notwithstanding the remonstrances of some of his fellow-Academicians, who thought the practice undignified. The course of his studies was only interrupted by occasional visits to his native city, and to Scotland. On the occasion of one of these visits he gave the finishing touches to his trio of Judiths. In 1840 and again in 1841 Etty went to the Netherlands to study the masterpieces of Rubens. Two years later he was in France collecting materials for what he called "his last epic," his famous picture of "Joan of Arc." In 1848 he retired to York, where many of his best pictures are to be seen. There are fine examples of Etty in the National Gallery and in South Kensington Museum, London, notably "Youth at the Prow and Pleasure at the Helm." A collection of his pictures was shown in London in the summer of 1849; on Nov. 13 of that year he died. He received the honours of a public funeral in his native city.

The key to Etty's choice of subjects and his manner of painting is to be found in his own words: "When I found that all the great masters of antiquity had become thus great through painting great actions, and the human form, I resolved to paint nothing else; and, finding God's most glorious work to be Woman, that all human beauty had been concentrated in her, I resolved to dedicate myself to painting, not the draper's or milliner's work, but God's most glorious work, more finely than ever had been done."

See Etty's autobiography, published in the *Art Journal* for 1849, and A. Gilchrist, *Life of William Etty, R.A.* (2 vols., 1855).

ÉTUDE (Fr.), in music, has not only the ordinary meaning of a study or technical exercise but also that of a finished composition, based on the treatment of a particular type of phrase or figure and possessed therefore of a study-like character. An étude in this sense may be a study, not only from the standpoint of the performer, but also from that of the composer, as an essay in the handling of the material which he has chosen. Chopin's études for the pianoforte contain some of his choicest inspirations, while Schumann's Études Symphoniques may be similarly ranked.

ETYMOLOGY, that part of linguistics which deals with the origin or derivation of words (Gr. ἔτυμος, true, and λόγος, account). The Greek word ἔτυμος, as applied to words, referred to the meaning rather than to the origin, and the Stoics asserted that the discovery of τὸ ἔτυμον would explain the essence of the

things and ideas represented by words. Plato, in the *Cratylus*, approaches the modern view and jests at *e.g.*, the derivation of *οὐρανός*, heaven, *ἀπὸ τοῦ ὁρᾶν τὰ ἄνω*, from looking at things above. Until the comparative study of philology and the development of phonetic laws, the derivation of words was largely a matter of guesswork. This popular etymology, or *Volksetymologie* has had much influence in the form which words take (*e.g.*, "crawfish" or "crayfish," from the French *crevis*, modern *écrevisse*), and has frequently occasioned homonyms. Skeat has embodied in certain canons some principles to be observed in giving the etymology of a word: (1) Ascertain the earliest form and use of the word. Observe chronology. (2) Observe history and geography; borrowings are due to contact. (3) Observe phonetic laws, especially as regards the relation of consonants in Aryan languages, and compare vowel sounds. (4) In comparing two words, A and B, of the same language, of which A has fewer syllables, A must be taken *prima facie* to be the more original word. (5) In comparing two words, A and B, of the same language and the same number of syllables, the older form can usually be distinguished by the principal vowel's sound. (6) Teutonic strong verbs and the Latin "irregular verbs" are commonly to be taken as primary, related forms as derivative. (7) The *whole* of a word ought to be accounted for; and, in tracing changes of form, infringement of phonetic laws is suspicious. (8) Mere resemblances of form and in sense between unrelated languages are not to be regarded. (9) When words in two languages are *too much* alike, one has probably borrowed from the other. (10) An explanation of an English word must *also* explain its cognate forms (Intro. to *Etym. Dict. of the Eng. Lang.* 1898).

An English word is either "the extant formal representative or direct phonetic descendant of an earlier (Teutonic) word, or it has been *adopted* (popularly) or *adapted* (in literature) from some foreign language"; finally, there is *formation, i.e.*, the combination of words or parts of words with each other or with formative syllables. (*See* Introduction to the Oxford *N.E.D.*, p. xx.) A further classification of words by origin is that into (1) naturals, *i.e.*, purely native words, like "mother," "house"; (2) perfectly naturalized foreign words, like "cat," "beef"; (3) denizens, words naturalized but keeping the foreign pronunciation, spelling and inflections, *e.g.*, "focus," "camera"; (4) aliens, *e.g.*, *menu, lakh, tarbush;* (5) casuals, *e.g.*, *bloc, Ausgleich*, differing from "aliens" in their temporary use. The full etymology of a word should include its phonetic descent, source, and, if of foreign origin, whether by adoption or adaptation, or, if *formed*, the origin of its several parts. (*See* also DICTIONARY.)

EU (ö), a town of north-west France, in the department of Seine-Inférieure, on the river Bresle, 64 m. N.N.E. of Rouen on the Ouest-État railway, and 2 m. E.S.E. of Le Tréport, at the mouth of the Bresle, which is canalized between the two towns. Pop. (1926) 5,438.

Eu (Augusta) was in existence under the Romans. The first line of its counts, supposed to be descended from the dukes of Normandy, had as heiress Alix (died 1227), who married Raoul (Ralph) de Lusignan. Through their granddaughter Marie, the countship of Eu passed by marriage to the house of Brienne. King John confiscated the countship in 1350, and gave it to John of Artois (1352). The countship passed, through heiresses, in the 15th century, to the house of Cleves, and to that of Lorraine-Guise. In 1660 Henry II. of Lorraine, duke of Guise, sold it to Anne Marie Louise d'Orléans, duchesse de Montpensier (*q.v.*), who made it over (1682) to the duke of Maine, bastard son of Louis XIV., as part of the price of the release of her lover Lauzun. The second son of the duke of Maine, Louis Charles de Bourbon (1701–1775), bore the title of count of Eu. The estates of Eu were confiscated at the Revolution; but at the Restoration they were bestowed by Louis XVII. on the duchess-dowager of Orléans who, in 1821, bequeathed them to her son, afterwards King Louis Philippe. They were again confiscated in 1852, but were restored to the Orléans family by the National Assembly after the Franco-German War. The title of count of Eu was revived in the 19th century in favour of the eldest son of the duke of Nemours, second son of King Louis Philippe.

The extensive forest of Eu lies to the south-east of the town. The Gothic church of St. Laurent (12th and 13th centuries) has a choir with three tiers of ornamented buttressing and double arches between the nave pillars; the chapel of the Jesuit college (*c.* 1625) contains the tombs of Henry, third duke of Guise, and his wife, Katherine of Cleves; and the château, begun by Henry of Guise in 1578, was continued by Mademoiselle de Montpensier in the latter half of the 17th century, and restored by Louis Philippe. In 1902 it was largely destroyed by fire. The town has a tribunal of commerce, and manufactories of casks and glass; the port has trade in grain and timber.

EUBOEA or **NEGROPONTE,** the largest island of the Greek archipelago, about 90 m. from north-west to south-east, and from 30 m. to 4 m. in breadth. Its mountains prolong the chains bounding Thessaly to east and south, and continue south into Andros, Tenos and Myconos islands. Three principal masses are separated by fertile lowlands. In the north the highest peaks are Mts. Gaetsades (4,436 ft.) and Xeron (3,232 ft.), the former famed for medicinal plants in antiquity, and for hot sulphurous springs near the coast at Aedipsos (mod. Lipsos), called the Baths of Heracles, used in antiquity by Sulla, and frequented now for the cure of gout, rheumatism and digestive disorders. Opposite the Maliac gulf is the promontory of Cenaeum, where the highest point, Lithada (2,221 ft.), retains the old name of the Lichades islands off the cape. Here, and on the mainland coast of Trachis, was the scene of the death of Heracles (Sophocles, *Trachinian Women*). Almost facing the Gulf of Pagasae, the promontory Artemisium saw the naval battle between Greeks and Persians in 480 B.C.

In the centre, north-east of Chalcis, rises Dirphys (now Mt. Delphi, 5,725 ft.), whose bare summit carries snow till May, with pines and firs below, and then chestnuts and planes, one of the most conspicuous peaks in eastern Greece. At the south end, Mt. Ocha (now St. Elias, 4,830 ft.) is visible from Chios. The south-west promontory is Geraestus, the south-east, the dreaded Caphareus, overlooking the storm- and current-swept channel towards Andros. The whole east coast is rocky and harbourless, especially the part called "the hollows" where a Persian squadron went ashore in 480 B.C. Consequently the main traffic from the north Aegean to Athens used the inshore channels.

In Greek belief, Euboea had been torn from the mainland by earthquake, and ancient writers record tremors and volcanic activity here. The northern strait is at narrowest 1½ m. wide, and at Chalcis, the Euripus channel, divided by a rock with ruined castle, is bridged, on the Boeotian side by a stone arch, on the Euboean, which is navigable, by an iron swing-bridge. The first bridge here was built by Boeotians when Euboea revolted from Athens in 411 B.C., making it "an island to all but themselves," and impeding Athenian supplies of gold and corn from Thrace, timber from Macedon, and horses from Thessaly. Extraordinary changes of current occur in the "fair-swirling" Euripus: Strabo says that it varied seven times daily, Livy more discreetly that it is "irregular." Modern shipping is warned of its vagaries by signals. The name was corrupted in the middle ages to Evripo and Egripo, and extended to the whole island. The Venetians, observing the "black bridge," mis-heard it as Negroponte.

Euboea has few streams. In the north-east the Budorus flows into the Aegean from two headwaters which may be the Cereus and Noleus, sheep drinking of which became in one case white, in the other black. On the north coast, near Histiaea, issues the Callas, with alluvial fertility, enhanced, as in the Achmet-aga district of the Budorus, by foreign settlers after the War of Liberation; south of Chalcis, the Lelantus, whose fertile coast plain was a breeding-place of horses, and a standing cause of feud between Chalcis and Eretria. In Chalcis the aristocracy were nicknamed *Hippobotae*, "ranchers." The mountains have good pasture for sheep and cattle; the latter seem to have given Euboea its name. Forests are still extensive, and are better managed than formerly, but have been widely devastated by goats, fires, and reckless felling. In the mountains were formerly mines of iron and copper, and ancient Chalcis had fame from its swords. Magnesite is largely worked for export; lignite coal

on the coast at Kymi, for local steamships; and from Carystus, at the south end, comes the green and white *cipollino* marble, very popular with architects in imperial Rome, and now again exported abundantly. The scenery of Euboea, especially in the northern highland, is among the most beautiful in Greece.

Population.—Euboea had other early names, Macris and Doliche from its length, Ellopia and Abantis from sections of its people. Various tribes occupied its principal districts: in the north, Histiaei and Ellopes from Thessaly; in the centre Curetes and Abantes (the latter prominent in Homer); in the south Dryopes from Thessaly, in Carystus, Dystus, and Styra. The modern population is no less various: Greeks have immigrated from the mainland and other islands; the south is occupied, like much of Andros, by Albanians; and there are Vlach (Rouman) shepherds in the hill-country. Only one family remains of the English "philhellene" settlers of a century ago.

History.—The history of Euboea is mainly that of its chief cities Chalcis and Eretria (*q.v.*) on either margin of the Lelantine plain, about which their quarrels involved distant allies of each. Both were of Ionian origin, and colonized early in Campania, north-east Sicily, and in the Chalcidic promontory of the Macedonian coast. The later and more important colonies were from Chalcis. "Euboic" weights and measures facilitated intercourse, and were adopted by Athens (*see* SOLON) and many Ionian cities, and by Corinth with modifications. Eretria, repaying later the help of Miletus in the Lelantine war, by the raid on Sardis about 500 B.C. (*see* IONIA) incurred utter destruction by Persia in 480 B.C. Thenceforward, though Eretria was rebuilt, and Histiaea and Carystus were prosperous, Chalcis predominated, but Athens imposed a cleruchy (*q.v.*) there in 506 B.C. and at Histiaea after the revolt of 446. The excuse for Athenian domination in Euboea lay in its production of corn and cattle, its command of the sea-routes from north and east, and its strategical value in hostile hands. In 411, Euboea recovered independence, and took subordinate part in fourth-century politics. After the battle of Chaeronea (338 B.C.) it fell to Philip II. of Macedon. Philip V. fortified and garrisoned Chalcis, with Demetrias on the gulf of Pagasae, and Corinth, to be the "fetters of Greece." Hence its importance also for the Romans, in their wars with Antiochus and Mithridates.

Euboea (Negroponte) becomes once more important after the Fourth Crusade. In the partition of the Eastern empire among Latin adventurers, it was divided into three fiefs, but all soon became valuable dependencies of Venice; and the lion of St. Mark may still be seen over the sea-gate of Chalcis, and elsewhere. At length, in 1470, Chalcis was captured by Mohammed II., and the whole island fell to the Turks. In 1688, Francesco Morosini besieged Chalcis for three months, but in vain. After the Greek War of Independence, the island was included, in 1830, in the new Greek State. In 1899 it became a separate province. It produces much grain and exploits its minerals mainly with foreign capital.

(J. L. MY.)

EUBULIDES, a native of Miletus, Greek philosopher and successor of Eucleides as head of the Megarian school. Indirect evidence shows that he was a contemporary of Aristotle, whom he attacked. Tradition says that Demosthenes was one of his pupils. His name has been preserved chiefly by some celebrated, though false and captious, syllogisms of which he was the reputed author. He wrote a treatise on Diogenes the Cynic and a number of comedies. (*See* MEGARIAN SCHOOL.)

EUBULUS, of Anaphlystus, Athenian politician, was a persistent opponent of Demosthenes and was chiefly instrumental in securing the acquittal of Aeschines (who had been his own clerk) when accused of treachery. Eubulus took little interest in military affairs, and was (at any rate at first) a strong advocate of peace at any price with Philip of Macedon. He devoted himself to matters of administration, especially in the department of finance. He proposed the law providing that any proposal to use the Theoric fund for military purposes should be punished with death. As one of the chief members of an embassy to Philip, Eubulus allowed himself to be won over, and henceforth did his utmost to promote the cause of the Macedonian. The indignant remonstrances of Demosthenes failed to weaken Eubulus's hold on the popular favour, and after his death (before 330 B.C.) he was distinguished with special honours, which were described by Hypereides in a speech now lost. Eubulus had a considerable reputation as an orator, but none of his speeches has survived, nor is there any appreciation of them in ancient writers. Aristotle (*Rhetoric*, i. 15. 15) mentions a speech against Chares, and Theopompus (in his *Philippica*) gave an account of his life, extracts from which are preserved in Harpocration.

See Demosthenes, *De corona*, pp. 232, 235; *De falsa legatione*, pp. 434, 435, 438; *Adversus Leptinem*, p. 498; *In Midiam*, pp. 580, 581; Aeschines, *De falsa legatione, ad fin.*; Index to C. W. Müller's *Oratores Attici*; A. D. Schäfer, *Demosthenes und seine Zeit* (1885).

EUBULUS, Athenian poet of the Middle comedy, flourished about 370 B.C. Fragments from about 50 of the 104 plays attributed to him are preserved in Athenaeus. They show that he took little interest in political affairs, but confined himself chiefly to mythological subjects, and to ridicule of the Tragedians, especially Euripides. His language is pure, and his versification correct.

Fragments in T. Kock, *Comicorum Atticorum fragmenta*, ii. (1884).

EUCALYPTUS, a large genus of trees of the family Myrtaceae, indigenous, with only a few exceptions, to Australia and Tasmania. In Australia the eucalypti are commonly called "gum-trees" or "stringy-bark trees." The genus, from the evidence of leaf-remains, appears to have been represented by several species in Eocene times. The leaves are leathery, hang obliquely or vertically, and are studded with glands which contain a fragrant volatile oil. The petals cohere to form a cap which is discarded when the flower expands. The fruit is surrounded by a woody cup-shaped receptacle and contains very numerous minute seeds. The eucalypti are rapid in growth, and many species are of great height, *E. amygdalina*, the tallest known tree, attaining to as much as 480ft., exceeding in height the Californian big-tree (*Sequoia gigantea*), with a diameter of 81ft. *E. globulus* is the blue gum tree of Victoria and Tasmania. The flowers are single or in clusters, and nearly sessile. This species attains a height of 375ft. Since 1854 it has been successfully introduced into the south of Europe, Algeria, Egypt, Tahiti, New Caledonia, Natal and India, and has been extensively planted in California, and, with the object of lessening liability to droughts, along the line of the Central Pacific railway. By aqueous distillation of the leaves a complex straw-coloured fluid is obtained of sp. gr. 0·910 to 0·930, and soluble in its own weight of alcohol. About 70% of this fluid consists of a volatile oil—Eucalyptol—which passes over between 347° and 351° F., and crystallizes at 30°F. It consists chiefly of a terpene and cymene. Eucalyptus oil also contains, after exposure to the air, a crystallizable resin derived from eucalyptol. The dose of the oil is ½ to 3 minims. Eucalyptol may be given in similar doses, and is preferable for purposes of inhalation. The oil derived from *E. amygdalina* contains a large quantity of phellandrene, which forms a crystalline nitrate, and is very irritating when inhaled. The oils from different species of *Eucalyptus* vary widely in composition.

Internally, eucalyptus oil acts as other volatile oils. Like quinine, it arrests the normal amoeboid movements of the polymorphonuclear leucocytes, and has a definite anti-periodic action; but it is a very poor substitute for quinine in malaria. In large doses it is an irritant to the kidneys, by which it is largely excreted, and is a marked nervous depressant, abolishing the reflex functions of the spinal cord and ultimately arresting respiration by its action on the medullary centre. An emulsion with gum solution has been used as a urethral injection, and has been given internally in pulmonary tuberculosis and other microbic diseases of the lungs and bronchi. The oil has acquired an extraordinary popular reputation in influenza, but there is no evidence to show that it has any marked influence upon this. It has been used as an antiseptic by surgeons, and is an ingredient of "catheter oil." *Eucalyptus rostrata* and other species yield eucalyptus or red gum,

which must be distinguished from Botany Bay kino. Red gum is powerfully astringent and is given internally, in doses of 2 to 5 grains, in cases of diarrhoea and pharyngeal inflammation. Red gum is official in Great Britain. *E. globulus, E. resinifera* and other species yield what is known as Botany Bay kino, an astringent dark-reddish amorphous resin, which is obtained in a semi-fluid state by making incisions in the trunks of the trees. The kino of *E. gigantea* contains a notable proportion of gum. J. H. Maiden enumerates more than thirty species as kino-yielding. From the leaves and young bark of *E. mannifera* and *E. viminalis* is procured Australian manna, a hard, opaque, sweet substance, containing melitose. On destructive distillation the leaves yield much gas, 10,000 cu. ft. being obtained from one ton. The wood is extensively used in Australia as fuel, and the timber is of remarkable size, strength and durability. Maiden enumerates nearly 70 species as timber-yielding trees including *E. amygdalina,* the wood of which splits with remarkable facility, *E. botryoides,* hard, tough and durable and one of the finest timbers for shipbuilding, *E. diversicolor* or "karri," *E. globulus, E. leucoxylon* or ironbark, *E. marginata* or "jarrah" (*see* JARRAH WOOD), *E. obliqua, E. resinifera, E. siderophloia* and others. The timber is often very hard, tough and durable, and useful for shipbuilding, building, fencing, etc. The bark of different species of *eucalyptus* has been used in paper-making and tanning, and in medicine as a febrifuge.

For further details *see* Baron von Müller's monograph of the genus, *Eucalyptographia* (Melbourne, 1879–84); J. H. Maiden, *Useful Native Plants of Australia* (1889); R. T. Baker and H. S. Smith, *A Research on the Eucalyptus Especially in Regard to Their Essential Oils* (Sydney, N.S.W., 1920); R. N. Parker, *Eucalyptus Trials in the Simla Hills, Calcutta* (1925).

EUCHARIS, in botany, a genus of plants of the family Amaryllidaceae, containing six species, natives of Colombia. *Eucharis amazonica* of *Egradiflora* is the best-known and most generally cultivated species. It is bulbous, with broad-stalked leaves, and an erect scape 1½ to 2 ft. long, bearing an umbel of three to ten large, white, showy flowers. The flowers resemble the daffodil in having a prominent central cup or corona. The plant is propagated by removing the offsets, which may be done in spring, potting them singly in 6-in. pots. It requires good loamy soil, with sand enough to keep the compost open, and should have a good supply of water. Other species met with in gardens are *E. Bakeriana, E. Mastersii, E. Lowii* and *E. Sanderii.* A remarkable hybrid between *Eucharis* and the allied genus *Urceolina* has been produced to which the compound name *Urceocharis* is given.

EUCHARIST, one of the ancient titles of the central sacramental rite of the Christian Church (Gr. εὐχαριστία, "Thanksgiving"). The term is probably to be regarded as the Greek equivalent of the Hebrew *Berakhah,* the Jewish "blessing" addressed to God at meals for and over the food and drink. It is in this sense that the term was originally used in connection with the common meal of the early Christian community, at which the "blessing" or "thanksgiving" had special reference to Jesus Christ. As early as the 2nd century it was applied also to the food and drink, the bread and wine, over which the blessing had been pronounced. Finally, it was used of the whole meal, and of the rite into which the meal developed.

Other names of the eucharist are: the *Lord's Supper,* so called from its particular reference to, and connection with, Jesus; *Communion,* Gr. κοινωνία and *Holy Communion,* from the fellowship with Jesus Christ and Christian believers, of which the observance was taken to be both the expression and the means; *Mass* Lat. *missa* or *missio,* a work of no doctrinal significance, derived from the "dismissal" with which Christian services of worship concluded (*see* LITURGY) and eventually used of any complete service, eucharistic or otherwise, its restriction to the eucharist dating from the close of the 4th century. In the Greek and Russian Churches the rite is known as *The Divine Liturgy,* Gr. ἡ θεία λειτουργία as being pre-eminently the public service rendered to God by the Christian society. In the Syriac-speaking, Coptic and Armenian Churches it is designated by words meaning "oblation" or "present" (Syr. *Qurbana;* Copt. *Prosfora;* Arm. *Patarag;* mod. *Badarak*). The Abyssinian Church terms it "the consecration" (Eth. *Qeddase*).

In the New Testament.—The earliest attestation of the eucharist is supplied by St. Paul in 1 Cor. xi. 17–34. From this passage it is clear that it was the practice of the Corinthian Christians to assemble for a common meal of religious significance. Paul protests that the Corinthians' conduct of the meal had nullified its religious significance. Faction and class-division, instead of fellowship and unity, characterized the gatherings. It was apparently the custom of each believer to bring his own provisions for the meal and to eat them without waiting for, or sharing with, his fellows. The rich, therefore, had more than they required, while the poor went hungry. This, according to Paul, was no "Lord's Supper." It was a mere satisfaction of the appetite for which their homes were the proper place.

The Lord's Supper is of a different order. Paul proceeds to recall the tradition of it which he had committed to the Corinthians and which he had received from (ἀπό) the Lord:—"The Lord Jesus on the night in which He was betrayed took bread, and having given thanks, broke it and said: This is My body which is for your sake. This do in memory of Me. Likewise also the cup after supper, saying: This cup is the new covenant in My blood. This do, as often as you drink it, in memory of Me." Then, in explanation of this command, Paul adds "For as often as you eat this bread and drink this cup, you proclaim (καταγγέλλετε) the death of the Lord until He come." It follows that the believer may not partake of the bread and the cup in disregard of the sacred character of the action in which they have figured. Paul continues: "Wherefore whoever eats the bread or drinks the cup of the Lord unworthily, shall be guilty of the body and blood of the Lord. Let a man prove himself, and thus let him eat of the bread and drink of the cup. For he who eats and drinks, eats and drinks judgment to himself if he do not rightly judge the body."

The passage presents difficulties, and it is too allusive to allow a detailed picture of the eucharist as observed by Paul to be drawn from it. Certain points, however, are beyond doubt. Though the Lord's Supper was not a liturgy, it was nevertheless a formal observance. Paul regards it as a presentation of Christ's death, which according to Christ's quoted words was of the nature of a covenant-sacrifice. Paul further taught that the Supper rested on the authority of Christ, in virtue of His institution of it and express command to continue it. The eucharist, therefore, for Paul was in some way a re-presentation of the crucifixion, ordained by Christ Himself to assure to His followers the enjoyment, until His proximate return, of the blessings which the crucifixion, as a covenant-sacrifice, had secured. This interpretation, however, cannot be taken as current outside the sphere of Pauline influence; Paul himself fails to cite the general assent of Christians in confirmation of the tradition which he asserts.

According to Paul, the eucharist was instituted at the Last Supper of Jesus with His disciples. Fuller accounts of this meal are found in the Synoptic Gospels. The passages in question are Mark xiv. 22–25, Matt. xxvi. 26–29, Luke xxii. 14–20; of these the oldest tradition, and next in order of time after Paul, is that of Mark. In substance the Synoptist and Pauline accounts are in agreement, with, however, two main exceptions. The Synoptists date the supper on the night of the Passover, and they omit the command to continue it. The *textus receptus* of Luke indeed includes the command, but the passage in which it occurs is an interpolation from the Pauline account; and whatever view be taken of the problem of the Lucan text, the command is no part of the original. The evidence, therefore, does not warrant the attribution to Jesus of the words "This do in memory of Me."

Two other sayings of Jesus at the supper appear in the Synoptist record. One is common to the three, though they report it in slightly differing forms: "I will not again drink of the product of the vine until that day when I drink it new in the Kingdom of God"; the other occurs in Luke alone: "I greatly desired to eat this Passover with you before I suffer, for I tell you that I will not eat it until it be fulfilled in the Kingdom of God."

The precise significance of the Synoptic record is difficult to ascertain. Jesus's words after the blessing of the cup may be held to give His sanction to a sacrificial view of His death; but

the Synoptist record is not an account of the institution of a sacrificial-sacramental action such as that described by Paul. Certain scholars have supposed that the Synoptist story implies a repetition of what Jesus did and said at the Supper. As a prelude to the narrative of Jesus's passion and death, however, the story need imply no more than that his death is to be interpreted, on His own authority, as a covenant-sacrifice. The two non-Pauline sayings suggest that the Supper was "an anticipation of the heavenly banquet in the kingdom" (the phrase is A. D. Nock's, *Early Gentile Christianity in Essays on the Trinity and Incarnation*), which Jesus's death was to inaugurate.

Both the date and the character of the meal raise a difficulty. According to the Synoptists, it was a Passover Supper, and was celebrated on the first evening of the Passover Feast. According to the Fourth Gospel, which gives no account corresponding with the accounts of Paul and the Synoptists, Jesus's Last Supper with His disciples occurred a day earlier, and was not Paschal in character. The objections to the Synoptist chronology are insuperable; the details of the meal, also, do not suggest a Passover Supper. The form of the tradition found in the Fourth Gospel is indubitably correct. The interpretation of Jesus's death in terms of Passover significance is perhaps a partial explanation of the form which the tradition takes in the Synoptist account.

The details of the Supper in the latter, however, throw some light on its character. They belong, apparently, to the ordinance known as the *Qiddush*. This was a domestic ceremony observed at home by a family or by a group of friends on the eve of a Sabbath or Feast-day, in "sanctification" of the day, hence its name. It was preceded by a social meal. Towards the close of the meal, the president of the group took a cup of wine and "sanctified" the day by reciting over the cup a blessing, which was, in effect, a thanksgiving for the Sabbath or Feast, or if they coincided, for both together. The cup was then given to the members of the group to partake of it. There was a similar blessing and breaking of bread. In the event of the coincidence of Passover and Sabbath, it was necessary to transfer the *Qiddush* from Friday, the Sabbath-eve, to Thursday, as Friday was reserved for the killing of the lambs and other Passover preparations. This Thursday *Qiddush,* nevertheless, was celebrated in the accustomed manner, and its blessing was a thanksgiving for the combined commemoration. It is hardly improbable that we have here the true explanation of the events reported of the Last Supper in the New Testament. Jesus, after the usual meal with His disciples, celebrated the *Qiddush,* and speaking and acting as is recorded, gave to it an eschatological import. Whether he called the bread his body during the meal or after the blessing of the *Qiddush* cup is of no consequence; the records are not clear on this point, and either would have been possible. It has been suggested that in the combined Passover-Sabbath commemoration we have also the explanation of the Synoptists' Passover tradition of the Supper. This may well have been a contributory factor.

But though the *Qiddush* accounts for the Last Supper, it affords no explanation of the origin of the eucharist. This perhaps is not now far to seek. Jesus and his disciples formed one of the *Chaburōth,* or "groups of friends," which were a feature of the religious-social life of contemporary Judaism. These groups met to discuss religious questions of mutual interest, to administer charity from their common fund, and for a common meal. The latter was of a formal religious kind, the president solemnly breaking and distributing bread over which he had first addressed a thanksgiving to God. "To break bread" was the general expression for eating the meal. The cup of wine was not essential, except at such a ceremony as the *Qiddush;* water was ordinarily sufficient, should drink be required. When, however, wine was drunk, the customary thanksgiving was first recited over it. Such a meal was a regular institution in the common life of Jesus and His disciples; it is of the background of the Gospels. The Last Supper and the Sabbath-Passover *Qiddush* was, therefore, no unusual occurrence. It represented consistent practice since Jesus had first formed the group. It is from this practice, rather than from any direct institution by Jesus, that the eucharist derives its origin. The practice was too firmly established for the group to abandon it, when its Master had been taken away; the primitive apostolic eucharist is no other than the continuation of Jesus's *chaburah* meal. This is the "breaking of the bread," Gr. ἡ κλάσις τοῦ ἄρτου of Acts ii. 42 (cf. *id.* ii. 46 and xx. 7). It was to become a distinctive feature of the life of Christian groups in every place.

For the original company of disciples the thought of the meal was inseparable from that of the presence of Jesus. How far they regarded the eucharist as the occasion of the presence of the risen Jesus with them cannot certainly be stated; the story of the Emmaus Supper and the accounts of the appearances in John xxi. 14, and Acts i. 4 (*cf.* Mark xvi. 14; Matt. xviii. 20) point to some such belief. How far a belief of this kind penetrated into the wider Christian circle is equally beyond ascertainment, but it is beyond question that the meal was now marked by particular reference to Jesus.

On this foundation there was variety both in the interpretation and in the manner of conducting the meal. For the earlier conservative Jewish element of the community, it was still primarily a *chaburah* meal of fellowship. In other and newer circles, as the death of Jesus came to be regarded as of central importance, the meal was inevitably related directly with what Jesus had done and said the day before He suffered, and became a constituent part of a wider doctrinal whole. The latter type of interpretation is illustrated in the Fourth Gospel and in the thought of Paul. In this treatment of the eucharist, the cup of wine is indispensable. The writer of the Fourth Gospel, though he omits mention of the blessing of the bread and the cup, nevertheless knows the story.

It is difficult to interpret John vi. except in reference to the Last Supper and to the eucharistic practice of the circle from which the Gospel proceeds. The sayings concerning "eating (τρώγειν) the flesh" and "drinking the blood" are to be understood of the bread and wine of the eucharist. This "realist" interpretation did not readily win wide acceptance in the writer's time:—"Many of His disciples when they had heard this said: 'This is a hard saying. Who can accept it?' . . . From that time many of His disciples went back and walked no more with him" (Jn. vi. 60, 66). But it was to attain increasing prominence as attention came to be concentrated on the Last Supper and as the former common meal assumed the features of a cultual act. As has been already noted, it was in process of becoming a cultual act within the sphere of Pauline influence at least half a century before the Fourth Gospel was written. This difference between the Pauline and Johannine lines of interpretation should, however, be observed; for the former, the emphasis and interest centre in the eucharistic action, for the latter, they centre in the eucharistic objects, the bread and the wine. Much of the history of the eucharist during the period under review consists in the combination and interplay of these two emphases and interests.

In the Sub-Apostolic and Patristic Periods.—The eucharistic diversity to which the New Testament points only gradually came to an end. In *The Teaching of the Twelve Apostles* (? A.D. 100) there are forms of thanksgiving over bread and wine, the latter being placed first, and a eucharistic prayer which is to be said "after being filled." The blessings of the bread and wine are reminiscent of the corresponding Jewish blessings. The *Didache* is the earliest document in which the term "eucharist" is used in its Christian technical sense, but in no one of its forms of prayer is there any reference to the body and blood of Jesus or to His crucifixion. Thanksgiving is offered to God over the cup "for the holy vine of David Thy servant," and over the bread "for the life and knowledge" which with the holy vine are made known "through Jesus Thy servant." The vine is suggestive of Psalm lxxx. 8–19, and signifies the true, the spiritual Israel, the Church, for the "gathering together" of which "into Thy Kingdom" prayer is made after the thanksgiving over the bread.

The eucharist of the *Didache* is still associated with a common meal, as the words "after being filled" indicate. The uppermost thought of its prayers is that of the community, blessed by God through Jesus, and of its unity. The one eucharistic loaf is taken

as symbolical of that unity (*cf.* 1 Cor. x. 17), and participation is restricted to authentic members of the community, the baptized. The "Lord's Day" is to be the occasion of the eucharistic celebration, which is held to be the fulfilment of Malachi i. 11: "In every place and time offer we a pure sacrifice." In spite of its divergences from what was to be the eucharistic norm, the *Didache* does not completely lack affinity with the norm, and traces its descent from New Testament practice. Divergences of other kinds are to be noted in *The Acts of John, The Vercelli Acts of Peter* and *The Acts of Thomas*. Though these proceed from unorthodox circles, they are nevertheless survivals of the diversity of tradition.

In the central Graeco-Roman Church, the eucharist had become an established "rite" by the middle of the 2nd century. It was not yet a "liturgy," but it had a fixed order, the matter of its prayers was settled, and its celebrant was duly authorized. *The Epistle to the Corinthians* of Clement of Rome (*c.* A.D. 96) had stated that Christ had fixed the worship to be performed, and the persons who should perform it.

Ignatius of Antioch (*c.* A.D. 108) insists that the eucharist, to be genuine (βεβαία) must "be celebrated by the bishop or by one whom he appoints" (Smyrn viii. 1). This is in the interest of unity, which is stressed no less by Ignatius than by the *Didache*. The normal celebrant of the eucharistic service, the bishop, is the local focus of Christian unit, as the eucharist itself is at once the symbol, the safeguard, and the means of that unity, as being "one flesh of our Lord Jesus Christ and one cup for union with His blood" (Philad. iv. 1). The Ignatian conception of the local church is the *chaburah,* extended and adapted to its extension; and it is noteworthy that the term *"agape"* which Ignatius uses for eucharist (Smyrn viii. 2) is the Greek equivalent of *chaburah.*

Ignatian references to the eucharist are, however, incidental; fuller information is to be found in Justin Martyr and Irenaeus, at the middle and end of the same century. Both these authors derive the eucharist from the Last Supper, and appear to know no other tradition. Both regard the bread and wine as in some sense the body and blood of Christ. How they are so, neither states; Jesus's words at the Supper are adduced as sufficient ground for the belief. According to Irenaeus, the bread "receiving the invocation of God . . . is eucharist, consisting of two parts, an earthly and a heavenly" (Adv. Haer. iv. 18). In virtue of the "heavenly," the eucharist can be as Ignatius had taught (Eph. xx. 2) following the Johannine thought (Jn. vi. 54 *sqq.*), "a medicine of immortality." In their view of the eucharistic objects, both Justin and Irenaeus are "realists," but their realism is a matter of imagination rather than of thought. Both writers further treat of the eucharist in sacrificial terms, seeing in it the fulfilment of Malachi i. 11. The sacrifice is one of praise and thanksgiving for creation and redemption, and the offering of it is commanded by Jesus Christ. Irenaeus considers the sacrifice to be an oblation of first fruits, which should be offered to God "not as though he is in need," but as tokens of thankfulness (Adv. Haer. iv. 17). Justin interprets the words "Do this in memory of Me" as "Offer this," and thinks of the eucharist as also a commemoration of Jesus Christ's passion. Justin and Irenaeus mark a definite stage in the development of the eucharist. No interpretation of it after their time differs fundamentally from theirs. Henceforward, in the main stream of Christian tradition, the eucharist is not regarded except as a continuation of the Last Supper, and its significance is believed to lie in the words: This is My body, This is My blood, and Do this in memory of Me.

The development of sacrificial theories of the eucharist is in some measure a Christian attempt to meet the pagan objection that Christians had no sacrifices and were, therefore, atheists; and in some measure also an attempt to solve the problem of post-baptismal sin and lapse, by so identifying the eucharistic action with the sacrifice of the cross as to make the former a means of securing the effects of the latter. Cyprian (A.D. 258) speaks of the eucharist as an offering of the body and blood of Jesus Christ, and a century later the eucharistic prayer of Sarapion conceives the liturgical action as "making the likeness of the death," so being a reconciliatory sacrifice.

Notice should here be taken of an important eucharistic conception and terminology, the symbolical, particularly connected with the names of Tertullian, Cyprian and Augustine, though it is not restricted to Africa and the West. The bread and wine are said to be figures, symbols, likenesses, or antitypes (figurae, imagines, σύμβολα, ὁμοιώματα, ἀντίτυπα) of the body and blood. They "re-present" (repraesentant) them, *i.e.,* make them present. The symbol is not the sign of an absent reality, but is in such a way associated with its reality that it is in some sense what it symbolizes and possesses the effect of the reality. A similar idea is applied to the liturgical action. This is a copy or analogue both of the Supper and of the passion in such a way "that as often as the memorial of the victim pleasing to Thee is celebrated, so often is the work of our redemption set in operation" (Leonian Secret in Muratori, *Liturgia romana vetus* i. 303–304).

The central section of the Canon of the Roman Mass (4th–5th century), is an example of the analogue. It is an imitation of the Supper in word and act, solemnly performed before God. As such it strictly has no moment of consecration, but the repetition of Jesus's words is necessary as completing the association of the analogue, both objects and acts, with the realities of the Supper. Hence the later transformation of these words into "the form of consecration." The central moment of the action is the offering of "the holy bread of eternal life, and the chalice of eternal salvation," the making of the memorial of Christ in accordance with the command: Do this. Here the analogue has passed from the Supper to the cross. The eucharist on this presentation of it is a sacrificial-sacramental action of saving efficacy, and the worshippers partake of the bread and the wine, not as a personal act of piety, but as participants in the saving transaction. This view, it will be observed, has points of contact with the Pauline in its stress upon the eucharistic action.

The symbolic theory was destined, however, to be superseded by a theory of the realist type. The simpler realism of Justin and Irenaeus in time proved unsatisfactory. If the bread and wine are to be regarded as the body and blood, the questions: How are they so? and What makes them so? must at some point arise; and the answers given to them must in their turn re-act upon eucharistic belief and practice.

Cyril, bishop of Jerusalem in A.D. 350, is the first to go beyond the earlier realism. His thought was, doubtless, moulded by the pneumatological controversies of his time, and by their effect upon the doctrines of incarnation and sacraments. Cyril teaches that the Holy Spirit, who is a living person within the Godhead, descends upon the bread and wine at the prayer of the celebrant, and changes them into the body and blood (Cat. Myst. v.). This is the first appearance of the Epiklesis, the normal Eastern form of consecration.[1] It is a departure which is to become a rule. A theologian contemporary with Cyril set himself to work out the implications of Cyril's idea. According to Gregory of Nyssa, the objects are "transmade" (μεταποιεῖσθαι) or "transelemented" (μεταστοιχειοῦν) into Christ's body and blood, just as, in His days on earth, bread and wine taken by Him as food were metabolized into His flesh and blood at digestion, the whole being dignified by its union with the Logos. Such is the effect of eucharistic consecration; it is real and objective, but for Gregory it is a change of relation, not of nature. Subsequent Greek speculation was content to re-echo the ideas and terms of Cyril and Gregory without further pursuing their lines of thought. When Greek orthodox eucharistic theology attains its final formulation in the *De Fide Orthodoxa* of John of Damascus (*c.* A.D. 759), these ideas and terms re-appear, though John advances beyond Gregory in his complete identification of the eucharistic objects with Christ's body and blood, and in his notion of the eucharistic body as identical with that born of Mary (*De Fid. Orth.* xiii.).

In its effect upon popular devotion and cultus, Cyril's conversion teaching was revolutionary and has proved permanent. Hitherto the intercessory prayer of the eucharistic service had not been connected with the central action. Cyril introduces them after the consecration and before communion, as being more efficacious at that point because presented with the "holy and

[1]See note at end of article.

most awful sacrifice," which is "Christ propitiating God" for men (*see* Cat. Myst. v.). John Chrysostom (A.D. 407) in whose service the intercessions occur in a similar position, holds the time after the consecration as specially propitious for prayer, particularly on behalf of the dead, as then "we supplicate the Lamb that taketh the sin of the world and that now lies (on the altar)" (Hom. in 1 Cor. xli. 4). Both here and elsewhere he uses language which suggests that prayer at the eucharist is to be offered to Christ, believed to be present in virtue of the consecration; and at all times he stresses the awfulness and solemnity of the eucharistic service. There is here a change in emphasis, which is, in fact, the forming of a new tradition, as it was a change made easily intelligible to the mass of worshippers by a corresponding development of ritual and ceremony, and therefore easily shaping cultual outlook and practice. The eucharist was now, and in the Greek Orthodox and kindred Churches continues to be, a propitiatory sacrifice, in which an awful Divine victim is offered with certain efficacy.

In the West the conversion theology was introduced by Ambrose of Milan (A.D. 397), who associates the consecration with the repetition of the words: This is My body, and This is My blood (De Myst. ix.). It succeeded in no more than partially establishing itself, since the thought of the West was dominated by Augustine (A.D. 430). More fully than had been done before, Augustine dealt with the notion and nature of sacraments; but he made little advance on the earlier theory. He continued, and in a measure explicated, the symbolic tradition; and his thought was destined to influence eucharistic thinking and discussion in the middle ages. He takes a sacrament to be the sign of a Divine thing; in it "one thing is seen, but another is understood" (Serm. cclxxii.). The bread and wine, therefore, sanctified to become sacraments of Christ's body and blood, are as such the means of communicating a supernatural gift, but are always to be distinguished from the gift. This view was not congenial to the forms of eucharistic devotion which were developing under the influence of the conversion theology. The latter, however, was never excluded from the West. Caesarius of Arles (A.D. 543) and Gregory the Great (A.D. 604) maintain it; and it appears in some of the prayers of the Latin sacramentaries. The petition in the present Roman Canon: "Which oblation do Thou bless . . . in order that it may be unto us the body and blood of Thy most dear son, Jesus Christ" (*Quam oblationem*) probably represents a middle position between the complete conversion theory on one hand, and on the other the symbolic teaching of the older form of the petition: "Bless unto us this oblation, because it is the figure of the body and the blood." The propitiatory theory of the sacrifice inevitably accompanied the conversion view, and likewise finds expression in the sacramentaries. The language of certain writers, among them Gregory the Great, suggests that the eucharist is a renewal of the sacrifice of Christ on the Cross.

From the middle of the 2nd century, some kind of reservation of the eucharist has been commonly practised. Justin attests that the consecrated objects were taken by deacons to those who could not be present at the gathering. At a later period, it was permitted to take away portions of the consecrated bread and to consume them at home. From the 4th century, the consecrated bread was reserved in a box on the altar or in a chamber attached to the church.

In the Middle Age.—In the East the conversion doctrine was established as the orthodox belief, and the middle age marked no advance upon, or withdrawal from, the position laid down by John of Damascus. In the West, on the other hand, the middle age was to see the conflict between the symbolic and conversion theologies and a decision in favour of the latter. The conflict began in A.D. 844 with the re-publication by Paschasius Radbertus, of Corbie, of his work *On the Body and Blood of the Lord.* This is the first systematic treatise on the eucharist. Paschasius asserted that the bread and wine are changed by consecration into the body and blood of Christ that were born of Mary. The change, however, is not apparent to the senses; it is inward and requires faith in order to be known. The sacramental gift, therefore, is spiritual in character. Paschasius was in the tradition of Ambrose, and he knew the teaching of John of Damascus, but he was not unaffected by Augustine.

He was answered by Ratramnus, also of Corbie, in a treatise under the same title. Charles the Bald had asked Ratramnus two questions: Is the eucharist Christ's body and blood in mystery or in sensible reality (in veritate?) and: Is it the body that was born of Mary and is exalted in heaven? Ratramnus's treatise is an answer to these questions. He proceeds to answer the first by defining the terms *mystery, figure* and *sensible reality. Mystery* denotes that which contains something hidden and is open only to the eye of faith. *Figure* (figura) is that which conveys its meaning under a veil. *Sensible reality* (veritas) is that which is set forth clearly and openly in its natural character. In the eucharist, bread and wine are received, but Christ's body and blood are understood. The latter, therefore, are received in *mystery* and *figure,* not in *sensible reality.* The second question Ratramnus answered negatively. Following Ambrose he distinguishes between the sacrament of the flesh and the sensible reality of the flesh. Christ suffered in the latter; the eucharist and the former are the same thing, the eucharistic body cannot, in consequence, be identified with the latter. The eucharist is Christ's body and blood, because in it the power of Christ is communicated. Ratramnus's treatise left unsolved the problem which Paschasius's doctrine raised, mainly because it suffered from the vagueness which characterized the Western symbolic tradition. Ratramnus's dissent from the conversion doctrine is unambiguous, but it is not clear whether he believed that the body and blood were truly, though not in *sensible reality,* present in the eucharist, or whether he held the eucharist to be no more than a means of conveying power to unite the recipient with Christ. Other writers of the period took part in the controversy. Hincmar and Remigius of Rheims, and Ratherius of Verona, siding with Paschasius, and Amalarius of Metz, Florus of Lyons, and Rabanus Maurus, taking the opposition; but these no more than the protagonists contributed towards the solution of the problem.

Two centuries elapsed before the question was again discussed. In the meantime the conversion teaching of Paschasius had gained wide acceptance, and was being interpreted in a materialistic sense. The mass was popularly believed to be the occasion of a physical miracle. The use of symbolic language was treated as a mark of unorthodoxy. The immediate cause of the second controversy was a letter written in A.D. 1050 by Berengar of Tours to Laufranc of Bec, condemning the doctrine of Paschasius and defending that put forward by Ratramnus. He was condemned by two councils, and required to sign a confession of faith to the effect that the consecrated bread and wine are not only a sacrament, but the real body and blood of Christ, and that these, "not only sacramentally, but in sensible reality (*in veritate*), are taken in the priests' hands." Berengar submitted, but later published his views at length, in his treatise, *On the Holy Supper.* He revives the symbolic teaching, appealing to Augustine and the prayers of the Roman mass. He allows a change of the bread and wine into the body and blood in the sense that they become signs of the latter by consacration; but he denied "subjective change" on the ground that such is impossible without a corresponding change in appearance and perceptible property. Berengar was as vague as Ratramnus. His contemporaries interpreted his language in more ways than one. Guitmund of Aversa understood him to teach a theory of impanation and invination, *i.e.,* that in the eucharist Christ assumes bread and wine, as at the incarnation he had assumed flesh. Berengar was required to sign a second declaration in 1079, affirming that the bread and wine are "substantially converted" (*substantialiter converti*) and that after consecration they are the real body and blood born of Mary "not only by way of sign and power of sacrament, but in property of nature and reality of substance." Berengar subscribed, and the conversion theology was victorious. Conversion, for the most part in, its crudest form, was now the orthodoxy of the West.

In the 12th and 13th centuries the balance was to some extent redressed. Scholasticism set it itself to re-examine, and within the limits of orthodoxy, to re-state the whole of sacramental doctrine. Orthodoxy consequently tied down the scholastics' eucharistic theory to conversion. Setting out from Augustine's distinc-

tion between the sacrament and that which it signifies, and from his definition of a sacrament as a visible sign of an invisible grace, they formulated their theory in terms of *substance* and *accidents*. Both terms had been used in the discussions of the previous century; and Berengar had already made the distinction between "subject" in the sense of *substance* and *accidents*. *Substance* denotes the underlying reality or being which constitutes a thing what it is and is not perceptible by the senses. *Accidents* are the properties and attributes which inhere in the substance, and which are perceptible by the senses. The substance in a thing can be perceived only by thought; likewise in the eucharist, the body and blood which are the substances of the sacrament can be apprehended only by faith. At the consecration the substances of the bread and wine change "by transition" (*per transitionem*) into the body and blood. The accidents remain as and what they were. They do not inhere in, and are not affected by, the body and blood; they exist *per se*. It is then the accident only, not the body, that is taken into the priest's hands. There is here a marked refinement of the view current in authoritative circles in the 11th century.

The term used to describe the change is "transubstantiation" (transubstantiatio): it occurs, seemingly for the first time, in the *Exposition of the Canon of the Mass*, attributed to Peter Damiani (A.D. 1072). The verb appears in the Definition of Faith of the Fourth Lateran Council (A.D. 1215): Christ's "body and blood are verily contained in the sacrament of the altar under the species of bread and wine, the bread being transubstantiated into the body and the wine into the blood, by Divine power." The context does not make it clear that the word "transubstantiated" is to be interpreted precisely in the sense outlined above, but the belief usually denoted by the term was general in the Western Church at the time of the Council.

It remained for Thomas Aquinas (A.D. 1227–1274) to cast the doctrine in its final form. Aquinas represents alike the farthest reach of the scholastic re-action from earlier mediaeval materialism, and the extreme of refinement in conversion doctrine. Treating of the presence of Christ in the eucharist, he states that it is not local, but is "after the manner of a substance" (*per modum substantiae*, Sum. Theol. iii. lxxvi. 1), so that where the sacrament is moved, Christ can be said to move only *per accidens*, not *per se* (S. T. iii. lxxvi. 6). Similarly, he affirms that the whole Christ, body and blood, is present in each particle of the sacrament and under each species by concomitance (iii. lxxvi. 1). The spiritual reception of the body and blood is dependent upon the disposition of the communicant; the wicked receive only sacramentally. Aquinas also addressed himself to the problem of the existence in the sacrament of the accidents of bread and wine when the substance was the body and the blood. He thinks that they exist in dimensive quantity, as though in a subject (*sicut in subjecto in quantitate dimensiva*, iii. lxxvii. 2); this is admittedly miraculous, though of course not thereby unreasonable.

The doctrine of transubstantiation was all but universally accepted. Some scholastics, however, challenged it, particularly those dissatisfied with the treatment of the problem of the continued existence of the accidents, conspicuous among whom was Wyclif. The doctrine had the twofold merit for its own time of harmonizing with current philosophy, and of satisfying the demand of popular religion for a miraculous conversion in the mass; but such was its dependence upon the scholastic philosophy that it was unintelligible apart from that philosophy and incapable of surviving its supersedence.

Throughout the middle age the doctrine of the eucharistic sacrifice was secondary to that of the eucharist itself. The earlier mediaeval theologians were content to accept the later patristic views; but, together with a new interest in the effects of the sacrifice, expiatory ideas early appeared and developed in conjunction with conversion teaching. Paschasius maintained that Christ, as priest and victim, offered himself in the mass for daily sins, though this offering is one with, and not a renewal of, that of the Cross. The expiatory idea quickly found favour, and passed to the scholastics as orthodox.

It was not until the 13th century that there was any scholastic attempt at an exact treatment of the subject, and that an examination of the nature and essentials of sacrifice was undertaken. Thomas Aquinas holds that the offering of sacrifice is a law of nature (S. T., ii. ii. lxxxv. 1) and that it is necessary that "something is done" to the object offered, *i.e.*, bread is broken, is eaten, and is blessed (ii. ii. lxxxv. 3). In the eucharist the consummation of the sacrifice consists in the consecration of the matter, not in the communion of the faithful; participation, however, is necessary to a sacrifice, and the priest communicates both for himself and as representative of the faithful (iii. lxxx. 12). The priest consecrates in the person and by the power of Christ (iii. lxxxiii. 1). The eucharist, therefore, is offered by Christ himself, and possesses the efficacy of the sacrifice of the Cross, of which it is representative and commemorative. As such it blots out the mortal sins of those for whom it is offered, according to their moral disposition, "as if the sacrament of penance had been administered to them" (Vasquez). There were protests against expiatory teaching from time to time during the middle age, but they made no mark. At the close of the period it was generally held that the mass was a sacrifice for actual sin, as the Cross was a sacrifice for original sin.

The effects of mediaeval eucharistic controversy on popular religion were manifold. Interest was inevitably concentrated on the mass and the sacrament. But the popular mind could not appreciate the subtleties of scholastic doctrine. Popular interpretation of transubstantiation was no less crude than in the case of earlier conversion doctrine. Legend told how the miniature figure of a man had been seen in the priest's hands at the elevation of the host, and it was believed that on certain occasions the host had bled on being broken by the priest.

In the 13th century, the moment of consecration, emphasized by the new ceremony of the elevation of the host—Eudes de Sully, bishop of Paris, was apparently the first to decree it in A.D. 1208—had become the climax of the eucharistic service; the elevation of the chalice was to follow a century later, and the significance of the ceremony was further increased by the accompaniment of censings, the lifting-up of lighted candles, and the ringing of bells. At the same time communion became increasingly infrequent. The introduction of the Festival of Corpus Christi in A.D. 1264 considerably encouraged eucharistic devotion.

A cultus of the reserved sacrament developed, and before the close of the period under review the ceremonies of exposition and benediction had made their first appearance in northern Germany (*see* E. Bishop, "Pastor Dreygerwolt's Diary," in *Liturgica Historica*, Oxford, 1922). The popular mind was also quick to seize on the bearing of the expiatory view of the sacrifice. Masses were multiplied with special intention, particularly for the repose of the souls of the dead. The exaggerations both of belief and practice which gathered around the eucharist in the middle age and the attendant growth of the power of the priests led irresistibly to the Protestant reaction of the 16th century. It should, however, never be forgotten that the eucharist, both the service and the sacrament, was at all times for not a few an occasion and stimulus of spirituality. The presentation of the service as a moving-picture, whether of the passion and death, or of the whole life, of Christ gave nourishment to the artistic imagination, and its effect is to be seen in the poetry, painting and sculpture of the middle age. For the majority also, the mass was the one means of contact with culture, and the sole avenue of escape from the hardship of environment. In spite of the abuses connected with it and with the system of which it was part, the mass has exercised an incalculable influence on the cultural and spiritual development of Western Europe.

REFORMATION AND POST REFORMATION

The Eucharist from 1500.—The offering of the sacrifice of the mass by the priesthood was the centre of the life of the mediaeval Church. When the Reformation reaffirmed the primitive idea of the priesthood of all believers, and transferred the centre of religious interest to the faith of the believing man, it was inevitable that the practice and theory of the mass, as it had come to be, should be challenged.

Luther.—In the *Praeludium de captivitate babylonica*, one of the three great reforming manifestoes of 1520, Luther denounced three "captivities," which the Papal Babylon had imposed upon the Church in the matter of the eucharist: (1) in conflict with the command of Christ and the teaching of St. Paul the cup was withheld from the laity; (2) the doctrine of the transubstantiation of the elements was enforced, though it had no foundation in Scripture and was objectionable in philosophy; and (3) the mass was regarded as a sacrifice. As against the doctrine of transubstantiation, Luther leaned to the alternative theory that the substances of the bread and wine remain, together with the substances of Christ's body and blood. This theory Luther had learnt from the later Nominalist scholastics who had declared it to be more rational and more biblical than the doctrine of transubstantiation, and had accepted the latter doctrine.

But it was in the sacrificial conception of the mass that Luther saw the gravest and most iniquitous corruption of the sacrament, for by the doctrine of the sacrifice of the mass it was implied that man could do a work which God would accept as a satisfaction for sin. The mass, according to Luther, was not a sacrifice, but a promise. It was a summary of the Gospel, whereby Christ promises to us, antecedent to our own merit, the forgiveness of our sins. This promise can be accepted by faith and faith alone. In the Latin mass of 1523 and the German mass of 1526 Luther translated his doctrine into practice. The main order of the mediaeval mass was allowed to stand when it had been purged of the sacrificial idea. This meant that the solemn offertory of the elements, and the canon of the mass were expunged. In place of the latter was substituted a simple recital of the words of institution.

Zwingli developed his eucharistic doctrine under different influences and in a different direction. Like Luther, he rejected the sacrifice of the mass. In the Lord's Supper we receive from God, we do not offer to Him. But, whereas Luther retained a realistic doctrine of the presence of Christ's body and blood in the elements received, Zwingli regarded the elements as *signs* of the broken body and outpoured blood. The word *est* in *Hoc est corpus meum* he interpreted as *significat*. Zwingli's teaching in this respect had affinity, as he himself claimed and as Luther allowed, with the characteristic Augustinian distinction between the *sacramentum* and the *res sacramenti*. The two leaders with Melancthon and Oecolampadius, met in conference at Marburg in 1529, and though they were able to agree on 14 articles of faith, they were obliged to register a difference in belief with respect to the corporal presence of Christ—the Sacrament. Luther maintained and Zwingli denied that the body and blood of Christ were received not only by the faithful, but also by the ungodly, recipient. An examination of Zwingli's teaching seems to show that in his earlier period, and again towards the end of his life, his teaching was less negative in form than during the controversy. He cannot without qualification be credited with Zwinglianism, as it was later understood.

Calvin.—The Importance of Calvin in respect of eucharistic doctrine lies in the rôle which he strove to fulfil, of mediator between the Zwinglian doctrine and the Lutheran. With Zwingli, he rejected the cumbersome doctrine of the ubiquity of Christ's glorified body whereby Luther had tried to combine belief in Christ's corporal presence in the sacrament with His exaltation to the right hand of God. But Zwingli, Calvin held, had allowed himself to be drawn by controversy into too much denial. The elements are not only *signs*, as Zwingli taught, of the spiritual grace, but also *instruments* whereby the grace is imparted to the faithful receivers. Calvin took as his starting point the session of Christ at the right hand of God. This meant that Christ shares in the omnipotence and majesty of God, therefore, though His glorified body is in heaven, Christ is able to project this power without spatial limitation. Thus Christ bestows upon the faithful receiver of the sacrament, not, indeed, the substance, but the saving power of His body. "We say that the body and blood of Christ are truly and efficaciously, but not naturally, offered to us. By this we mean that it is not the very substance of the body or the true and natural body of Christ that is there given, but all the benefits which Christ by His body has procured for us. The presence of the body is such as the intention of the sacrament requires." (*Instit.*, 1st ed., 1536, cap. iv., *Opera* i. p. 123.) Calvin further developed the idea that the life-giving virtue of Christ's glorified body is so diffused by the Holy Spirit that in the Supper the souls of the faithful are enabled to feed upon the substance of the glorified body (*see* Calvin on 1 Cor. xi. 24).

The Council of Trent.—The Roman Catholic Church replied to the eucharistic doctrines of the Reformers at the 13th and 22nd sessions of the Council of Trent. At the 13th session (Oct. 1551) the doctrine of transubstantiation was reaffirmed and an anathema pronounced against any who should affirm that "in the most holy sacrament of the eucharist the substance of the bread and wine remains together with the body and blood of our Lord Jesus Christ," or should deny "that wonderful and singular conversion of the whole substance of the bread into the body and of the wine into the blood, the appearances (*speciebus*) of the bread and wine alone remaining, which transformation the Catholic Church most fitly names transubstantiation." At the 22nd session (Sept. 1562) the mass was declared to be a true, proper, propitiatory sacrifice offered on behalf of the sins, penalties, satisfactions and other necessities of the faithful, both living and departed, and an anathema was pronounced against any who should affirm the sacrifice of the mass to be only a sacrifice of praise and thanksgiving, or a bare commemoration of the sacrifice completed on the Cross, or who should affirm it to be of benefit only to him who received it, and not also to the faithful living and departed.

Thus the Reformation and the Counter-Reformation of the 16th century left the Church of Rome and the Churches of the Reformation sharply opposed in their doctrine of the eucharist. Important attempts, to be noted later, were made from both sides during the 17th century to find a basis for agreement, but the gulf has never since been bridged. Among Protestants, too, the difference in eucharistic doctrine between Lutherans and Reformed, inherited from the 18th century, remained a dominant factor in the history of the Churches during the 17th century.

Alongside the two dominant types of Protestant eucharistic doctrine, the Lutheran and the Reformed, must be recognized a leaven of Socinianism which, in spite of the opposition of orthodox theologians, penetrated throughout the Churches of the Reformation. The Racovian Catechism (first published 1605, a year after the death of Faustus Socinus), rejects the Roman, the Lutheran and the Calvinistic forms of eucharistic teaching, and regards the Lord's Supper, not as a means of grace, but solely as a remembrance of the death of Christ. This type of interpretation grew increasingly influential with the spread of rationalism in the 18th century.

A different spirit inspired the Quakers who, alone of Christian sects, rejected on principle the outward sacramental rite: "The communion of the Body and Blood of Christ" wrote Robert Barclay "is inward and spiritual, which is the participation of his flesh and blood, by which the inward man is daily nourished in the hearts of those in whom Christ dwells, of which things the breaking of bread by Christ with his disciples was a figure, which they even used in the Church for a time, who had received the substance, for the cause of the weak; even as abstaining from things strangled and from blood, the washing of one another's feet and the anointing of the sick with oil, all which are commanded with no less authority and solemnity than the former; yet seeing they are but the shadows of better things, they cease in such as have obtained the substance." (*Apology,* Thesis Theol. xiii.)

The Reformation had appealed from the authority of the Church to the authority of Scripture, and it allowed no doctrine to be taught as necessary to salvation except such as could be proved from Scripture. The interest was dogmatic, and the dogmatic standpoint continued in the ascendant until about the middle of the 17th century.

Criticism.—But from the later years of the 16th century, there was a tendency and an increasing tendency, to carry theological debate from the sphere of dogma into the sphere of history. The Roman Catholic claimed that the Church had preserved in fact the original deposit of faith and appealed to the continuous testimony of history to make good his claim. This claim made it incumbent upon Protestants to show not only that the original texts of Scripture did not, in fact, support the corruptions and accretions which they rejected, but also how and when these corruptions had set in. This change in the field of controversy explains the character of some of the great works of the 17th century on the eucharist. Aubertin (Albertinus) *De Eucharistia,* 1655, was for long a standard work of reformed theology. It is divided into three books, of which the first establishes the scriptural teaching, the second examines the teaching of the fathers of the first six centuries, and the last traces the course of the corruption which changed the primitive doctrine into the transubstantiation of the contemporary Church of Rome. The fathers, Aubertin holds (p. 903), maintain a change in the elements *accidentaliter* by the addition of a special significance and grace, not a change *substantialiter,* though he allows that from the end of the 2nd and beginning of the 3rd century there was a tendency to assign "too much power and efficacy"—he speaks as a Protestant—to the eucharistic signs. But this tendency, in their teaching, was not peculiar to their theory of the eucharistic elements. It appears also in their attitude towards the waters of baptism (*q.v.*). The beginning of the idea of transubstantiation in the eucharist, he traces to Anastasius of Sinai in the 7th century.

On the other hand the Port Royalists, Nicole and Arnauld, in their monumental reply to the Protestant Claude, *La perpétuité de la foi de l'Église Catholique touchant l'Eucharistie* (1669) argue that if the substantial change in the elements was not a part of the original faith of the Church, it must have been a most notable innovation, that no such innovation can be proved to have taken place, and that, though the fathers do not use the term transubstantiation, they assume the truth of the idea. The doctrine has therefore remained the same through all the ages of the Church. This appeal to history lies behind the various attempts to heal the breach of the Reformation; which, from George Cassander in the 16th century to Leibnitz and Bossuet at the end of the 17th, engaged the thoughts of some of the best minds of Christendom. The hope was shared by some Protestants and some Catholics (without much encouragement from authority on either side) that Christian antiquity might form a common meeting ground for the sundered Churches.

England.—The appeal to antiquity was represented in all the communions of Christendom, but it was especially characteristic of the Church of England. The eucharistic teaching of the Anglican Prayer Book and Articles is broadly in line with that of Calvin. Transubstantiation is repudiated, and Article XXIX., *Of the wicked which eat not the Body of Christ in the use of the Lord's Supper,* rules out the Lutheran doctrine of the corporal presence of Christ. The affirmative statements of eucharistic doctrine, both in the Articles and in the Catechism, are in line with Calvin. But the 16th century divines of the reformed Church of England, from Cranmer onward, were remarkable for their appeal to patristic testimony in justification of their doctrinal reform, and in the 17th century High Anglican divines and others under the influence of Patristic teaching, tempered the eucharistic doctrine of the Reformation period with a cautious revival of the sacrificial idea. Andrewes was willing to call the eucharist not only the commemoration of a sacrifice but also, and alternatively, a commemorative sacrifice. Joseph Mede, a Cambridge *savant* of no definite school in theology, complained that all Western Christendom, whether Roman or Protestant, had forgotten the primitive idea attested by Irenaeus, that the bread and wine are offered in sacrifice to God in recognition of His Lordship of creation; and Mede further maintained that it was not incompatible with the Reformed religion to allow that Christ is offered in the eucharist—though commemoratively only.

Such teaching, it should be added, never passed unchallenged in the Church of England. Thus Cudworth, the Cambridge Platonist, in reply to Mede, denied that the eucharist could be properly spoken of as a sacrifice. The proper idea, Cudworth maintained, was that it was a symbolical feast upon a sacrifice. But Mede's doctrine was taken up by influential divines, such as Bishop Bull and Dr. Grabe. In their doctrine of the presence of Christ in the eucharist the Anglo-Catholic divines of the 17th century remained essentially true to the Calvinian type. Even Thorndyke, who, perhaps, represents the most advanced Anglican teaching of the century on the eucharist, carefully stops short of affirming a *substantial* presence of the body and blood and emphatically denies a *substantial* change in the elements. "Calvin's words (about the presence of Christ)" said Cosin "agree so well with the style and mind of the primitive fathers that no Reformed Catholic could desire to use any other."

Daniel Waterland (1683–1740) continued on into the 18th century the tradition of the old learned Anglican theology. In his treatise on the eucharist he has two extremes in view: (1) the developments of eucharistic doctrine among the non-jurius divines, supported by their friend, Johnson, in the Established Church, and (2) the reduced interpretation of the Supper as a purely commemorative rite advanced by Bishop Hoadley. Waterland himself follows in the line of Cranmer and Hooker. He will not allow the idea of a material sacrifice of bread and wine, nor will he allow that Christ is offered in the eucharist. "We do not offer Christ to God in the eucharist, but God offers Christ to us in return for our offering ourselves." He also finds the idea of the union of the Spirit with the elements (akin to the doctrine of the Greek Church, favoured by Johnson and the non-jurius) to be "a gross notion and groundless." "If it were admitted," he adds, "Yet could it not make the elements, in any just sense, our Lord's body, but the notion would resolve into a kind of 'impanation' of the Spirit, for the time." *Doctrine of Eucharist* ch. vii. *fin.*

This line of teaching criticized by Waterland, which represents the consecration in the eucharist as effected through the invocation of the Spirit upon the elements, as in the Greek liturgies, had left its mark upon the First Prayer Book of Edward VI., and though it disappeared from the Prayer Book of 1552, it was revived in the Scottish book of 1637. It has been maintained—though not exclusively—in the Scottish Episcopal Church, and through that Church was transmitted to the Episcopal Church of America. When Bishop Seabury was consecrated first bishop of the American Episcopal Church he recommended to his congregations in Connecticut an office for the communion which conformed closely to the Scottish type. In 1789 the Convention of the American Church drew up an office in which an invocation of the Spirit was retained, but they brought the language expressing the intention of the prayer into close conformity with the invocation which opens the consecration prayer in the English Prayer Book. The "Deposited Book" of 1927 proposed to authorize a consecration prayer for the Church of England which included an invocation of the Holy Spirit upon the elements.

Waterland holds a peculiarly representative position in the tradition of Anglican theology. His works remained a standard authority with the High Churchmen of pre-Tractarian days, and so late as 1880 his treatise on the eucharist was reprinted by special request of the archbishops of Canterbury and York as "a safe and perspicuous guide to these tenets on the sacrament of the Lord's Supper, which, as a matter of fact, have been held by the great majority of the ablest and most learned theologians of the Reformed Church of England." (Preface by Bishop Jackson of London.)

The Tractarian divines went behind Waterland and revived the more advanced teaching of some of his predecessors of the 17th century, while in their doctrine of the Real Presence, they and their successors have often been insensitive to limits which the 17th century divines had instinctively respected. It has been

characteristic of much of the modern teaching of the High Church school in the Church of England to relate the sacraments more closely to the Incarnation than to the Atonement. It has been a congenial thought that the Divine life which appeared incarnate in Jesus Christ is perpetuated through the sacramental principle in the Church. Eucharistic sacrifice is frequently interpreted by this school as answering to the idea that Christ continually presents in heaven the sacrifice of Himself.

Recent Tendencies.—The revival in sacramental practice has not been confined to the Anglo-Catholic party in the Church of England, nor, indeed, to the Anglican communion. The function of the sacraments in the life of the Church meets to-day with a wider recognition than it did a century ago. At the same time there is a tendency with all parties to sit loosely to the old formulations. If Christ's body can no longer be thought of as existing *locally* in heaven, all the terms of thought are changed. Moreover, the historical criticism of the Bible and the felt necessity of relating the religion of the Bible to the general religious history of mankind, as we are now coming to see it, inevitably react upon current ideas of the Christian sacraments. In particular the anachronism of trying to extract a theory of the Presence from a few words of Christ (themselves differently reported by different writers) is widely recognized.

Various movements, religious and intellectual, have long since weakened the attachment of the Lutheran and Reformed Churches of the Continent to the classical forms of eucharistic doctrine which they inherited from the age of the Reformation. Pietism was impatient of theology, and Rationalism was disposed to regard the old language of mystical communion as mere metaphor for moral obligation. The revival of religious thought and feeling in the last century encouraged a more sympathetic attitude to the confessional statements of doctrine, and the traditions of confessional orthodoxy have never died out. But it is worthy of notice that the two most influential Protestant theologians of the last century, Schleiermacher and Ritschl, wished to propound a conception of the eucharist suited to the faith of a Protestant Church, which should transcend the differences inherited from the 16th century. True to Reformation principles Schleiermacher would exclude any idea that the body of Christ is offered in sacrifice. He would not allow that the body and blood of Christ should be supposed to stand related to the bread and wine independently of the act of communion. On the other hand the Church must affirm connection between the reception of the bread and wine and the spiritual reception of the flesh and blood of Christ. He points out that the difference between Luther and Calvin in their answer to the question: What do the wicked receive? would disappear with the disappearance of unworthy partaking.

Ritschl starts out from the communal character of the sacrament. In the sacrament the Church thankfully acknowledges that sacrificial death of Christ on which its own existence depends. The value of the sacrament to the individual is the assurance of forgiveness guaranteed to him primarily by the Church, but ultimately by Christ Himself. The confessional differences as to the manner of the presence of Christ's body and blood cannot be resolved by an appeal to the words of institution, and it is to be noted that the confessional doctrines of the presence of the body and blood all fail to recognize that the bread *broken* and the wine *outpoured* present the body and blood as emblems of Christ's *death*. Moreover, it is manifest that Christ intended that all believers should unite in the action, not that they should separate in their celebration, according to the interpretation which they put upon the action. The confessional dispute makes it impossible for the sacrament to be, in practice, the uniting action of the Church (*Unterricht in der christlichen Religion,* 3rd ed., Bonn, 1886, sec. 90).

There is affinity between this teaching of Ritschl and Harnack's provocative judgment on Luther's eucharistic doctrine. Luther declares once and again that word and sacrament alike contain the forgiveness of sins, and that in this alone their whole value consists. That is the essential saving truth of the Gospel. Unfortunately, Luther allowed himself to become entangled in the idea that the body in the sacrament is not the natural and historical body of Jesus, but the body glorified. This opened the way to the thought of a union with Christ through the eucharist, more intimate and more mystical than through the Word. Here, according to Harnack, lies the worst of heresies, for vague feeling is thus exalted over faith. And for this reason the "mystical" Calvinian teaching on the Supper is of all the Reformed doctrines the least satisfactory, for it unites the defects of Zwingli with the defects of Luther. Luther provides the corrective to himself. The truth is, that while the various sensible signs under which the Word is presented are of importance, since they bring the word of Jesus Christ close to the heart, yet they are unable to add anything to the power of the Word (*Hist. of Dogma,* E.T. vol. vii. p. 258 seq.).

With reference to the Epiklesis mentioned on p. 795 it should be noted that a petition for the descent of the Spirit upon the bread and wine was not entirely a novelty. An example of an earlier form occurs in the eucharistic prayer of the *Verona Fragments,* which contain parts of a Latin translation of a lost Greek work, probably the *Apostolic Tradition* of Hippolytus (A.D. 235). This prayer asks, not that the bread and wine may be changed by the Spirit's descent, but that the recipients may partake of them "for the fulfilling of the Holy Spirit (*in repletionem spiritus sancti*) to the strengthening of faith in truth"; and it should be noticed that the conception of the Spirit implied in the *Fragments* is undeveloped. In these respects the Verona type of invocation is essentially different from Cyril's Epiklesis.

EUCHRE, a game of cards. The name is supposed by some to be a corruption of *écarté,* to which game it bears some resemblance; others connect it with the Ger. *Juchs* or *Jux,* a joke, owing to the presence in the pack, or "deck," of a special card called "the joker"; but neither derivation is quite satisfactory. The "deck" consists of 32 cards, all cards between the seven and ace being rejected from an ordinary pack. Sometimes the sevens and eights are rejected as well. The "joker" is the best card, *i.e.* the highest trump. Second in value is the "right bower" (from Dutch *boer,* farmer, the name of the knave), or knave of trumps; third is the "left bower," the knave of the other suit of the same colour as the right bower, also a trump: then follow ace, king, queen, etc., in order: Thus if spades are trumps the order is (1) the joker, (2) knave of spades, (3) knave of clubs, (4) ace of spades, etc. The joker, however, is not always used. When it is, the game is called "railroad" euchre. In suits not trumps the cards rank as at whist. Euchre can be played by two, three or four persons. In the cut for deal, the highest card deals, the knave being the highest and the ace the next best card. The dealer gives five cards to each person, two each and then three each, or vice versa: when all have received their cards the next card in the pack is turned up for trumps.

Two-handed Euchre.—If the non-dealer, who looks at his cards first, is satisfied, he says, "I order it up," *i.e.* he elects to play with his hand as it stands and with the trump suit as turned up. The dealer then rejects one card, which is put face downwards at the bottom of the pack, and takes the trump card into his hand. If, however, the non-dealer is not satisfied with his original hand, he says "I pass," on which the dealer can either "adopt," or "take up," the suit turned up, and proceed as before, or he can pass, turning down the trump card to show that he passes. If both players pass, the non-dealer can make any other suit trumps, by saying "I make it spades," for example, or he can pass again, when the dealer can either make another suit trumps or pass. If both players pass, the hand is at an end. If the trump card is black and either player makes the other black suit trumps, he "makes it next"; if he makes a red suit trumps he "crosses the suit"; the same applies to trumps in a red suit, *mutatis mutandis.* The non-dealer leads; the dealer must follow suit if he can, but he need not win the trick, nor need he trump if unable to follow suit. The left bower counts as a trump, and a trump must be played to it if led. The game is five up. If the player who orders up or adopts makes five tricks (a "march") he

scores two points; if four or three tricks, one point; if he makes less than three tricks, he is "euchred" and the other player scores two. A rubber consists of three games, each game counting one, unless the loser has failed to score at all, when the winner counts two for that game. This is called a "lurch." When a player wins three tricks, he is said to win the "point." The rubber points are two, as at whist. All three games are played out, even if one player win the first two. It is sometimes agreed that if a score "laps," *i.e.* if the winner makes more than five points in a game, the surplus may be carried on to the next game. The leader should be cautious about ordering up, since the dealer will probably hold one trump in addition to the one he takes in.

Three-handed (Cut-throat) Euchre.—In this form of the game the option of playing or passing goes round in rotation, beginning with the player on the dealer's left. The player who orders up, takes up, or makes, plays against the other two; if he is euchred his adversaries score two each; by other laws he is set back two points, and should his score be at love, he has then to make seven points.

Four-handed Euchre.—The game is played with partners, cutting and sitting, and the deal passing, as at whist. If the first player passes, the second may say "I assist," which is the same as "ordering up," or he may pass. If the first player has ordered up, his partner may say "I take it from you," which means that he will play alone against the two adversaries, the first player's cards being put face downwards on the table, and not being used in that hand. Any player can similarly play "a lone hand," his partner taking no part in the play. Even if the first hand plays alone, the third may take it from him. Similarly the dealer may take it from the second hand, but the second hand cannot take it from the dealer. If all four players pass, the first player can pass, make it, or play alone, naming the suit he makes. The third hand can "take it" from the first, or play alone in the suit made by the first, the dealer having a similar right over his own partner. If all four pass again, the hand is at an end and the deal passes. The game is five up, points being reckoned as before. If a lone player makes five tricks his side scores four: if three tricks, one: if he fails to make three tricks the opponents score four. It is not wise for the first hand to order up or cross the suit unless very strong. It is good policy to lead trumps through a hand that assists, bad policy to do so when the leader adopts. Trumps should be led to a partner who has ordered up or made it. It is sometimes considered wise for the first hand to "keep the bridge," *i.e.*, order up with a bad hand, to prevent the other side from playing alone, if their score is only one or two and the leader's is four. This right is lost if a player reminds his partner, after the trump card has been turned, that they are at the point of bridge. If the trump under these circumstances is not ordered up, the dealer should turn down, unless very strong. The second hand should not assist unless really strong, except when at the point of four-all or four-love. When led through, it is generally wise, *ceteris paribus,* to head the trick. The dealer should always adopt with two trumps in hand, or with one trump if a bower is turned up. At four-all and four-love he should adopt on a weaker hand. Also, being fourth player, he can make it on a weaker hand than other players. If the dealer's partner assists, the dealer should lead him a trump at the first opportunity; it is also a good opportunity for the dealer to play alone if moderately strong. If a player who generally keeps the bridge passes, his partner should rarely play alone.

Extracts from Rules.—If the dealer give too many or too few cards to any player, or exposes two cards in turning up, it is a misdeal and the deal passes. If there is a faced card in the pack, or the dealer exposes a card, he deals again. If anyone play with the wrong number of cards or the dealer plays without discarding, trumps being ordered up, his side forfeits two points (a lone hand four points) and cannot score during that hand. The revoke penalty is three points for each revoke (five in the case of a lone hand), and no score can be made that hand; a card may be taken back, before the trick is quitted, to save a revoke, but it is an exposed card. If a lone player expose a card, no penalty; if he lead out of turn, the card led may be called. If an adversary of a lone player plays out of turn to his lead, all the cards of both adversaries can be called, and are exposed.

Bid Euchre.—This game resembles "Napoleon" (*q.v.*). It is played with a euchre deck, each player receiving five cards, the others being left face-downwards. Each player "bids," *i.e.,* declares and makes a certain number of tricks, the highest bidder leading and his first card being a trump. When six play, the player who bids highest claims as his partner the player who has the best card of the trump suit, not in the bidder's hand: if it is among the undealt cards, which is ascertained by the fact that no one else holds it, he calls for the next best, and so on.

See Dick and Fitzgerald, *Two-handed and Four-handed Euchre* (1897); The U.S. Playing Card Co., *Euchre and how to play it* (Cincinnati, 1897).

EUCKEN, RUDOLF CHRISTOPH (1846–1926), German philosopher, was born on Jan. 5, 1846, at Aurich in East Friesland. He studied at Göttingen under Lotze, and at Berlin under Trendelenburg, whose ethical tendencies and historical treatment of philosophy attracted him. From 1871 to 1874 Eucken taught philosophy at Basle and from 1874 to 1920 held the chair of philosophy at Jena. In 1908 he was awarded the Nobel prize for literature. He died on Sept. 15, 1926.

Eucken's early works deal with the philosophy of Aristotle, but his later ones are mainly concerned with ethical and religious problems. Rejecting naturalism on the ground that the feeling of *ought* is inexplicable if man is only a derivative of natural processes, and distrusting pure intellectualism, he maintains that man is the meeting place of nature and of spirit, and that it is his duty and privilege to overcome his non-spiritual nature by incessant active striving after the spiritual life which involves all faculties, especially will and intuition. Historical religion is often merely a means of consolation and may become contracted, but true culture advances both form and energy and seeks a total coherency.

Eucken's chief works are:—*Die Methode der aristotelischen Forschung* (1872); *Die Grundbegriffe der Gegenwart* (1878; Eng. trans. 1880); *Geschichte der philos. Terminologie* (1879); *Die Einheit des Geisteslebens* (1888); *Die Lebensanschauungen der grossen Denker* (1890; Eng. trans. W. Hough and Boyce Gibson, *The Problem of Human Life,* 1909); *Der Wahrheitsgehalt der Religion* (1901); *Thomas von Aquino und Kant* (1901); *Gesammelte Aufsätze* (1903); *Philosophie der Geschichte* (1907); *Der Kampf um einen geistigen Lebensinhalt* (1896); *Grundlinien einer neuen Lebensanschauung* (1907, Eng. trs., 1911); *Einführung in die Philosophie der Geisteslebens* (1908; Eng. trans., *The Life of the Spirit,* F. L. Pogson, 1909); *Der Sinn und Wert des Lebens* (1908; Eng. trans., 1909); *Hauptprobleme der Religions-philosophie der Gegenwart* (1907); *Können wir noch Christen sein* (1911, Eng. trs., 1914); *Erkennen und Leben* (1912, Eng. trs., 1913); *Collected Essays* (ed. translated 1914); *Der Trager des deutschen Idealismus* (1915); *Mensch und Welt* (1918); *Was bleibt unser Halt* (1918) and *Lebens Erinnerungen* (1921, Eng. trs. 1921). *See* W. R. Boyce Gibson, *Eucken's Philosophy of Life* (1906) and *God with Us* (1909); H. Pöhlmann, *R. Euckens Theologie* (1903); O. Siebert, *Euckens Welt- und Lebensanschauung* (1904); K. Kesseler, *Euckens Bedeutung für das moderne Christentum* (1912); W. Tudor Jones, *The Philosophy of Eucken* (1914); M. Booth, *Eucken: His Philosophy and Influence* (1913); J. Budde, *Welt- und Menschheitsfragen in der Phil. Euckens* (1921). *See* Überweg, *Grund. der Gesch. der Phil.*, Pt. 4 (1923) for full bibliography.

EUCLASE, a rare mineral, occasionally cut as a gem-stone. Like beryl, it is a silicate of beryllium and aluminium, but hydrogen is also present; the formula is $HBeAlSiO_5$ or $Be(AlOH)SiO_4$. It crystallizes in the monoclinic system as striated prisms terminated by acute pyramids. Cleavage is perfect, parallel to the clinopinacoid, and this renders the stone fragile with a tendency to chip, hence its name from the Greek εὖ, "easily," and κλάσις, "fracture." The colour is generally pale-blue or green, though sometimes the mineral is colourless. When cut it resembles certain kinds of beryl (aquamarine) and topaz, from which it may be distinguished by its specific gravity (3·1). Its hardness (7·5) is rather less than that of topaz. Euclase occurs with topaz near Ouro Preto, Brazil, and with topaz and chrysoberyl in the goldbearing gravels of the river Sanarka in the southern Urals.

EUCLID (Eucleides) (*c.* 450–374 B.C.), founder of Megarian school of philosophy, born at Megara, and became a devoted

disciple of Socrates. When a decree was passed forbidding the Megarians to enter Athens, he and his friends withdrew to Megara. It has been conjectured that this was the period of Plato's residence in Megara, of which indications appear in the *Theaetetus*. He is said to have written six dialogues, of which only the titles remain. For his doctrine (a combination of the principles of Parmenides and Socrates) *see* MEGARIAN SCHOOL.

EUCLID (in Greek *Eukleides*), Greek mathematician (*fl.* about 300 B.C.), probably received his early mathematical training at Athens from the pupils of Plato; but we know nothing for certain of the circumstances of his life except that he taught and founded a school at Alexandria in the time of Ptolemy I., who reigned from 306 to 283 B.C. Mediaeval translators and editors mostly called him *Megarensis*, through confusion with the philosopher Eucleides of Megara, Plato's contemporary; this error was finally exposed by Commandinus in 1572. Proclus tells the story of Euclid's reply to King Ptolemy, who asked whether there was any shorter way in geometry than that of the *Elements*—"There is no royal road to geometry." Another anecdote relates that a pupil, after learning the very first proposition in geometry, wanted to known what he would get by learning these things, whereupon Euclid called his slave and said, "Give him threepence since he must needs make gain by what he learns."

Euclid's great work is the *Elements* (στοιχεῖα) (*see* GEOMETRY), in 13 books; of the books formerly purporting to be books xiv., xv., the first, by Hypsicles (2nd century B.C.) adds some interesting theorems about the regular solids, two of which it attributes to Aristaeus and Apollonius respectively; the second, much inferior, was written, at least in part, by a pupil of Isidorus of Miletus in the 6th century A.D.

The names of some earlier compilers of *Elements* are handed down; the first was Hippocrates of Chios (5th century B.C.), famous for his quadrature of certain *lunes,* intended to lead up to the squaring of a circle; the latest before Euclid was Theudius, whose text-book was that in use in the Academy and was probably that from which Aristotle drew his illustrations. The older elements were at once superseded by Euclid's and then forgotten. For his subject-matter Euclid doubtless drew upon all his predecessors; but it is clear that the whole design of his work was his own; he evidently altered the arrangement of whole books, redistributed propositions between them, and invented new proofs where the new order made the earlier proofs inapplicable; his changes began at least as early as i. 5 (the *pons asinorum*), since Aristotle cites a different proof of that theorem. He incorporated, too, the splendid new discoveries of Eudoxus and Theaetetus; book v. expounds Eudoxus's wonderful theory of proportion applicable to commensurable and incommensurable magnitudes alike; books x. and xiii. owe much to the original investigations of Theaetetus into (*a*) irrationals of different classes and (*b*) the geometry of the five regular solids, while book xii. uses Eudoxus's "method of exhaustion" for the purpose of proving that circles are to one another as the squares, and spheres are to one another as the cubes, on their diameters, and of finding the solid content of a pyramid, a cone and a cylinder. Books i.–iv. and vi. may be said to represent, roughly, the essence of the Pythagorean geometry, while books vii.–ix. on the elementary theory of numbers again owe something to the Pythagoreans.

It seems clear that the famous postulate 5 (the parallel postulate) is due to Euclid himself. No trace of such a postulate appears in Aristotle; Euclid then, realizing that some postulate is necessary to establish the theory of parallels, deliberately framed one, stating it in the direct form most useful for his purpose in that it gives a criterion by which to judge whether two lines drawn in a construction will or will not meet. The use of the postulate or some equivalent is the mark of Euclidean geometry. Many attempts to prove the postulate were made by prominent mathematicians from ancient times onwards. Gauss was the first to affirm, and Beltrami the first to establish (1868), the impossibility of proving it. The first to consider seriously the possibility of other hypotheses was Saccheri (*Euclides ab omni aevo vindicatus,* 1733), though he tried to prove that Euclid's was the only true one. Lobachewsky (1826) and (about the same time) J. Bolyai were the first to work out systematically a non-Euclidean geometry, while Riemann developed another in 1854.

It is safe to say that no other scientific text-book in the world has remained in use practically unchanged for more than 2,000 years. In this country it was not till the middle of the 19th century that a so-called "away from Euclid" movement began, which has led to the appearance of a multitude of rival text-books of geometry giving the substance of Euclid's early books in so many different forms as to produce a state of chaos in geometrical teaching which calls for remedy; but the text-book that shall really replace Euclid has not yet been written and probably never will be.

The following are the other works of Euclid which are extant; the first two belong to elementary geometry.

1. The *Data,* containing 94 propositions, has for its object to prove that, if certain elements in a figure are given, then other things are given, *i.e.,* can be determined. A systematic collection of such results must obviously be of great use in facilitating and shortening the analysis preliminary to the solution of a problem. The following is an example: *If two straight lines contain a given area in a given angle, and if the difference, or the sum, of them be given, then shall each of them be given;* this gives the geometrical solution of the simultaneous algebraical equations $y \pm x = a$, $xy = b^2$, or the equivalent quadratic equation in a single variable.

2. A book *On divisions* (*of figures*) was discovered in Arabic at Paris and edited by Woepcke in 1851. John Dee was the first to find (in Latin) a similar treatise by one Muhammad Bagdadinus which, in 1563, he handed to Commandinus, who published it in Dee's name and his own in 1570. The genuine treatise has now been restored and edited by R. C. Archibald (Cambridge, 1915). The type of problem dealt with is that of dividing a given figure (*e.g.,* a triangle, a parallelogram, a quadrilateral, a circle, or a figure bounded by an arc of a circle and two straight lines) by one or more straight lines into parts equal, or having given ratios, to one another or to other given areas.

3. The *Optics* of Euclid is extant in Greek in two forms, one being Euclid's own treatise and the other a recension by Theon. The *Catoptrica* (edited by Heiberg in the same volume) is not by Euclid but is a later compilation from ancient works on the subject.

4. The *Phaenomena,* extant in Greek, is a treatise on the geometry of the sphere intended for use in astronomy, and is similar in content to the work of Autolycus *On the Moving Sphere.*

5. A work on the *Elements of Music* is attributed to Euclid by Proclus and Marinus. Of two extant treatises of the kind the first, *Sectio Canonis,* giving the Pythagorean theory of music, is scarcely Euclid's in its present form, but may have been abstracted from the genuine *Elements of Music* by some less qualified editor. The *Introductio harmonica* is not by Euclid but by Cleonides, a pupil of Aristoxenus.

Of lost geometrical works by Euclid all except one, the *Pseudaria,* belonged to higher geometry.

1. The purpose of the *Pseudaria* was, we are told, to distinguish, and to warn beginners against, different types of fallacies to which they are liable in geometrical reasoning unless they have firmly grasped the principles and are guided by them alone.

2. The *Porisms,* in three books, was an advanced work of which Pappus gives a summary account with lemmas designed for use with it (*see* PORISM).

3. The *Conics,* in four books, corresponded in content to the first four books of Apollonius's *Conics,* though Apollonius added new theorems and generalized the treatment throughout. Euclid still called the conics by their old names, "Sections of a right-angled cone, an obtuse-angled cone, and an acute-angled cone" respectively; it was Apollonius who first gave them the names "parabola," "hyperbola," "ellipse," arising out of his generation of them all from one circular cone, in general oblique. Euclid was, however, aware that an oblique section of any right cone or cylinder gives a "section of an acute-angled cone" (ellipse).

4. Regarding the *Surface-Loci* (τόποι πρὸς ἐπιφανείᾳ), in two books, mentioned by Pappus, we can only conjecture that the

loci dealt with were *loci on surfaces,* perhaps also loci which *are* surfaces. Conics would appear to have entered into the subject, for one of the lemmas to the treatise given by Pappus contains a complete proof of the focus-directrix property of all three conics: a fact which further suggests that Euclid was acquainted with this property and assumed it as known (though it does not appear in Apollonius's *Conics*).

A fragment in Latin, *De levi et ponderoso,* included in Gregory's edition of Euclid, contains a statement of the principles of Aristotle's dynamics, but is not by Euclid; and there seems to be no independent evidence that Euclid wrote on mechanics at all.

TRANSLATIONS AND EDITIONS

This notice of Euclid would be incomplete without some account of the earliest and the most important translations and editions of the *Elements.* In ancient times Heron and Pappus of Alexandria, Proclus and Simplicius, all wrote commentaries. Theon of Alexandria (4th century A.D.) brought out a new recension of the work, with textual changes and some additions; Theon's version was the basis of all published Greek texts and translations therefrom until, early in the 19th century, Peyrard, discovered in the Vatican the great ms.gr. 190 containing an ante-Theonine text. Boëtius (about 500 A.D.) is said to have translated the *Elements* into Latin, but the geometry of the Pseudo-Boëtius which we possess contains no more than fragments of such a translation (the definitions of book i., the postulates and axioms, the enunciations of the propositions of book i. and of some propositions of books ii., iii., iv., but no proofs, except of props. 1–3 of Book i.). Arabic translations were made (1) by al-Hajjāj b. Yūsuf b. Maṭar, first for Hārūn ar-Rashīd (786–809) and again for al-Ma'Mūn (813–833); (2) by Isḥāq b. Ḥunain (d. 910); the latter translation was revised by Thābit b. Qurra (d. 901); the Isḥāq-Thābit version and six books of the second (abridged) version by al-Hajjāj survive, the former in the Bodleian, the latter at Leyden; (3) a third Arabic version was that of Naṣīraddīn aṭ-Ṭūsī (b. 1201); one form of this was printed at Rome in 1594.

The first extant Latin translation of the *Elements* was made (about 1120) by Athelhard of Bath, who obtained a copy of an Arabic version in Spain, whither he went disguised as a Mohammedan student. Next, Gherard of Cremona (1114–87) translated from the Arabic the "15 books of Euclid" as well as the commentary on books i.–x. by an-Nairīzī (about 900). The first Latin translation to be printed was that of Johannes Campanus (13th century), also made from the Arabic; Campanus's translation was more complete than Athelhard's, but he evidently used the latter, since the definitions, postulates, axioms, and the 364 enunciations are word for word the same in both translations. The first printed edition of the *Elements,* containing Campanus's translation (now rare), is a beautiful production by Erhard Ratdolt (Venice, 1482) with margins of 2¼in. and with figures in the margin; Ratdolt claims that no one before his time had been able to print diagrams like letters; 1482 saw two forms of the book (differing in the first sheet); others came out in 1486 and 1491. The first translation from the Greek was made by Bartolomeo Zamberti and appeared at Venice in 1505.

The *editio princeps* of the Greek text was brought out at Basle in 1533 by Simon Grynaeus the elder, with a preface addressed to a notable Englishman, Cuthbert Tonstall (1474–1557). Unfortunately the mss. used were two of the 16th century, which are among the worst.

The first English translation was that of Sir Henry Billingsley (1570), who was lord mayor of London in 1596–97, a magnificent volume of 928 folio pages, with a preface by John Dee: *The Elements of Geometrie of the most auncient Philosopher Euclide of Megara. Faithfully (now first) translated into the English toung, by H. Billingsley, Citizen of London.*

The most important Latin translation is that of Commandinus (1572), which was closely followed by Gregory and all translators down to Peyrard, including Simson.

The great Oxford edition (1703), in Greek and Latin, by David Gregory, was still, until the appearance of Heiberg and Menge's new text, the only edition of the complete works of Euclid. Peyrard's Greek text, published in three volumes between 1814 and 1818, and containing the *Elements* and the *Data,* represents the first approach to a better text, in so far as it adopted or recorded the readings of the Vatican ms.gr. 190; it was accompanied by translations into Latin and French. The edition of books i.–vi., in Greek and Latin, by Camerer and Hauber (Berlin, 1824–25) is valuable for its exhaustive notes, while E. F. August's Greek text of books i.–xiii. (1826–29) still further improved upon Peyrard's. All texts are now superseded by *Euclidis opera omnia* (8 vols., Leipzig, 1883–1916) edited by Heiberg and Menge; vols. i.–v. contain the *Elements* with Latin translation, apparatus criticus, scholia, etc., and vols. vi.–viii. the other extant works, scholia, fragments, etc. Book i. has been separately edited, with introduction and notes, by T. L. Heath (*Euclid in Greek Book I.,* Cambridge, 1918) and by G. Vacca (Firenze, 1916).

The number of editions in English is legion. We need here only mention Robert Simson's (first edition, in Latin and English, Glasgow, 1756, containing the *Elements* books i.–vi., xi., xii. and the *Data*); James Williamson's translations of the whole 13 books (vol. i., Oxford, 1781; vol. ii. London, 1788); T. L. Heath's *The Thirteen Books of Euclid's Elements,* translated from the text of Heiberg, with Introduction and Commentary, 3 vols. (Cambridge, 1908; second edition revised, with additions, 1926).

For more detailed accounts *see* Pauly-Wissowa's *Realencyklopädie;* G. Loria, *Le scienze esatte nell' antica Grecia,* pp. 188–268 (Milano, 1914); T. L. Heath, *History of Greek Mathematics,* vol. i., pp. 354–446 (Oxford, 1921). (T. L. H.)

EUCRATIDES, king of Bactria (*c.* 175–129 B.C.), came to the throne by a rebellion against the dynasty of Euthydemus, whose son Demetrius had conquered western India. His authority was challenged by a great many other pretenders and Greek dynasts in Sogdiana, Aria (Herat), Drangiana (Sijistan), etc., including Pantaleon, Agathocles, Antimachus, Antalcidas "the victorious" (*νικηφόρος*), and Plato, whose unique coin is dated from the year 147 of the Seleucid era (=166 B.C.). In the west the Parthian king Mithradates I. attacked Eucratides; he succeeded in conquering two provinces between Bactria and Parthia. But the principal opponent of Eucratides was Demetrius (*q.v.*) of India, who attacked him with a large army "of 300,000 men"; Eucratides fled with 300 men into a fortress and was besieged. But at last he beat Demetrius, and conquered a great part of western India. According to Apollodorus of Artemita, the historian of the Parthians, he ruled over 1,000 towns (Strabo xv. 686; transferred to Diodotus of Bactria in Justin 41, 4. 6); and the extent of his kingdom over Bactria, Sogdiana (Bokhara), Drangiana (Sijistan), Kabul and the western Punjab is confirmed by numerous coins, he is called "the great King Eucratides." On one his portrait and name are associated on the reverse with those of Heliocles and Laodice; Heliocles was probably his son, and the coin may have been struck to celebrate his marriage with Laodice, who seems to have been a Seleucid princess.

In Bactria Eucratides founded a Greek city, Eucratideia (Strabo xi. 516, Ptolem. vi. 11. 8). On his return from India Eucratides was (*c.* 150 B.C.) murdered by his son, whom he had made co-regent (Justin 41, 6). This son is probably the Heliocles just mentioned, who on his coins calls himself "the Just" (*βασιλέως Ἡλιοκλέους δικαίου*). In his time the Graeco-Bactrian kingdom lost the countries north of the Hindu Kush. Mongolian tribes, the Yue-chi of the Chinese, called by the Greeks Scythians, by the Indians Saka, among which the Tochari are the most conspicuous, invaded Sogdiana in 159 B.C. and conquered Bactria in 139. Meanwhile the Parthian kings Mithradates I. and Phraates II. conquered the provinces in the west of the Hindu Kush (Justin 41, 6. 8); for a short time Mithradates I. extended his dominion to the borders of India (Diod. 33. 18, Orosius v. 4. 16). When Antiochus VII. Sidetes tried once more to restore the Seleucid dominion in 130, Phraates allied himself with the Scythians (Justin 42, 1. 1); but after his decisive victory in 129 he was attacked by them and fell in the battle. The changed state of affairs is shown by the fact that on his later coins Heliocles passes over to a native silver standard, and his bronze coins

became quite barbarous. These and the coins of many other Greek kings of these times are records of a desperate struggle of the Greeks to maintain their nationality and independence in the Far East, which accelerated their destruction; about 120 B.C. almost the whole of eastern Iran was in the hands either of a Parthian dynasty or of the Mongol invaders, who are now called Indo-Scythians. Only in the Kabul valley and western India the Greeks maintained themselves about two generations longer (*see* MENANDER). (ED. M.)

EUDAEMONISM, in ethics, the name applied to theories of morality which find the chief good of man in some form of happiness (from Gr. *εὐδαιμονία,* literally the state of being under the protection of a benign spirit, a "good genius"). The term eudaemonia has been taken in a large number of senses, with consequent variations in the meaning of eudaemonism. To Plato the "happiness" of all the members of a state, each according to his own capacity, was the final end of political development. Aristotle, as usual, adopted "eudaemonia" as the term which in popular language most nearly represented his idea and made it the key-word of his ethical doctrine. None the less he greatly expanded the content of the word, until the popular idea was practically lost: if one be called *εὐδαίμων* ("happy") he must have all his powers performing their functions freely in accordance with virtue, as well as a reasonable degree of material well-being; the highest conceivable good of man is the life of contemplation. Aristotle further held that the good man in achieving virtue must experience pleasure (*ἡδονή*), which is, therefore, not the same as but the sequel to or concomitant of eudaemonia. Subsequent thinkers have to a greater or less degree identified the two ideas, and much confusion has resulted. Among the ancients the Epicureans expressed all eudaemonia in terms of pleasure. On the other hand attempts have been made to separate hedonism, as the search for a continuous series of physical pleasures, from eudaemonism, a condition of enduring mental satisfaction. Such a distinction involves the assumptions that bodily pleasures are generally different from mental ones, and that there is in practice a clearly marked dividing line—both of which hypotheses are frequently denied. Among modern writers, James Seth (*Ethical Princ.*, 1894) resumes Aristotle's position, and places eudaemonism as the mean between the ethics of sensibility (hedonism) and the ethics of rationality, each of which overlooks the complex character of human life. The fundamental difficulty which confronts those who would distinguish between pleasure and eudaemonia is that all pleasure is ultimately a mental phenomenon, whether it be roused by food, music, doing a moral action or committing a theft. There is a marked disposition on the part of critics of hedonism to confuse "pleasure" with animal pleasure or "passion"—in other words, with a pleasure phenomenon in which the predominant feature is entire lack of self-control, whereas the word "pleasure" has strictly no such connotation. Pleasure is strictly nothing more than the state of being pleased, and it is purely arbitrary to confine the word to those cases in which such stimuli are the proximate causes.

EUDEMOS OF RHODES, pupil of Aristotle, whose *Metaphysics* and *Physics* he revised. The *Eudemian Ethics* was probably not meant as an original work, but as an edition of a course on ethics by Aristotle. Eudemos gives a theological turn to the doctrines of his master and regards reason as the Divine element in our nature. Of his history of astronomy and mathematics, now lost, numerous extracts are to be found in later writers.

See the fragments edited by Spengel (1866; 2nd ed., 1870), and by Mullach (1881).

EUDOCIA AUGUSTA (*c.* 401–*c.* 460), the wife of Theodosius II., East Roman emperor, was born in Athens, the daughter of the sophist Leontius. The masterful Pulcheria, sister of the emperor Theodosius and co-empress, selected her for his wife. She was baptized and changed her name—Athenaïs—to Eudocia, and married Theodosius in 421. Soon she and Pulcheria fell out, but Theodosius contrived to live contentedly with both for many years: ultimately (440) she was disgraced, and withdrew to Jerusalem, but the facts of the case are obscure. She died at Jerusalem about 460, having devoted herself latterly to literature. Among her works were a paraphrase of the Octateuch in hexameters, a paraphrase of the books of Daniel and Zechariah, a poem on St. Cyprian and on her husband's Persian victories. A *Passion History*, which Zonaras attributed to Eudocia, is perhaps of different authorship.

See W. Wiegand, *Eudokia* (Worms, 1871); F. Gregorovius, *Athenaïs* (Leipzig, 1892); C. Diehl, *Figures byzantines* (1906), pp. 25–49; also THEODOSIUS. On her works *see* A. Ludwich, *Eudociae Augustae carminum reliquiae* (Königsberg, 1893).

EUDOCIA MACREMBOLITISSA (*c.* 1021–1096), daughter of John Macrembolites, was the wife of the Byzantine emperor Constantine X. After his death (1067), to protect her infant son and to enable the menace of the Turks on the eastern frontier to be met, she married Romanus Diogenes and made him regent. On his capture in 1071 she vacated the throne in favour of her son and retired to a convent. The Ἰωνιά ascribed to her really dates from the 16th century.

See J. Flach, *Die Kaiserin Eudokia Makrembolitissa* (Tübingen, 1876); P. Pulch, *De Eudociae quod fertur Violario* (Strasbourg, 1880); and in *Hermes*, xvii. (1882), p. 177 ff.

EUDOXIA LOPUKHINA (1669–1731), tsaritsa, first consort of Peter the Great, was the daughter of the boyarin Theodore Lopukhin. Peter, then a youth of 17, married her on Jan. 27, at the command of his mother. The marriage was in every way unfortunate. Accustomed from her infancy to the monastic seclusion of the *terem*, or women's quarter, Eudoxia's mental horizon did not extend much beyond her embroidery-frame or her illuminated service-book. From the first her society bored Peter unspeakably, and after the birth of their second, short-lived son Alexander, he practically deserted her. In 1698 she was sent to the Pokrovsky monastery at Suzdal for refusing to consent to a divorce, and in 1699 she took the veil. But the nuns persisted in regarding her as the lawful empress; and she was permitted an extraordinary degree of latitude, unknown to Peter, who dragged her from her enforced retreat in 1718 on a charge of adultery. Eudoxia was compelled to make a public confession. She was then divorced and consigned to the remote monastery of Ladoga, where she remained for ten years till the accession of her grandson, Peter II., when the reactionaries proposed to appoint her regent. She was escorted with great ceremony to Moscow in 1728 and exhibited to the people attired in the splendid, old-fashioned robes of a tsaritsa; but her friends soon saw that a convent was a much more suitable place for her than a throne. She disappeared again in a monastery at Moscow, where she died in 1731.

See R. N. Bain, *Pupils of Peter the Great* (1895), chaps. ii. and iv.; and *The First Romanovs* (1905), chaps. viii. and xii. (R. N. B.)

EUDOXUS of Cnidus, Greek savant, probably lived from 408 to 355 B.C. It is chiefly as a mathematician and astronomer that his name has come down to us (*see* ASTRONOMY, *History*). From a life by Diogenes Laërtius, we learn that he studied at Athens under Plato, but, being dismissed went to Egypt, where he remained for 16 months with the priests of Heliopolis; here he probably began his astronomical observations. He then founded a school in Cyzicus and the Propontis, and subsequently, accompanied by a number of pupils, went to Athens, where he took a part in public affairs, and towards the end of his life he returned to his native place, where he died. Strabo states that he discovered that the solar year is longer than 365 days by 6 hours; Vitruvius that he invented a sun-dial. The *Phaenomena* of Aratus is a poetical account of the astronomical observations of Eudoxus. Several works have been attributed to him, but they are all lost; some fragments are preserved in the extant Τῶν Ἀράτου καὶ Εὐδόξου φαινομένων ἐξηγήσεω βιβλία τρία of the astronomer Hipparchus (ed. C. Manitius 1894).

Eudoxus was a mathematician of some importance. He discovered that part of geometry which is now included in the fifth book of Euclid; the proofs he used were very much like those now used. He also originated several theorems of the "golden section" of a line. Eudoxus used the "method of exhaustion," which he had established to show that the volume of a pyramid or cone was one-third of the volume of a prism or cylinder on the

same base. The "method of exhaustion" was of great use to geometers, for, although it was very laborious, it was rigid and avoided the use of infinitesimals. It is probable that the proof that the volumes of spheres are to one another as the cubes of their radii is due to him. Eudoxus was the first astronomer to give a scientific explanation of the paths of planets. He assumed that each planet was fixed to a transparent spherical shell capable of rotating about an axis inside another spherical shell and so on. Four shells, each rotating in a different direction and performing a different function, were necessary for each planet. Altogether 26 spherical shells were necessary for the solar system, but later astronomers were forced to increase this number as new discoveries were made, and eventually the idea was superseded.

See J. A. Letronne, *Sur les écrites et les travaux d'Eudoxe de Cnide; d'après L. Ideler* (1841); G. V. Schiaparelli, *Le Sfere omocentriche di Eudosso* (Milan, 1876); T. H. Martin in *Académie des inscriptions*, Oct. 3, 1879; article in Ersch and Gruber's *Allgemeine Encyklopädie.*

EUDOXUS of Cyzicus (fl. *c.* 130 B.C.), Greek navigator, was employed by Ptolemy Euergetes to command a fleet exploring the Arabian Sea. After two successful voyages, Eudoxus left the Egyptian service, and proceeded to Cadiz to fit out an expedition for African discovery. Strabo says that he made at least two voyages southward along the coast of Africa.

See E. H. Bunbury, *Hist. of Ancient Geography*, ii. (1879); P. Gaffarel, *Eudoxe de Cyzique* (1873).

EUFAULA, a city of Barbour county, Ala., U.S.A., in the south-eastern part of the State, on the Chattahoochee river. It is served by the Central of Georgia railway and by river steamers. The population was 4,939 in 1920 (54% negroes) and was estimated locally at 7,000 in 1928. It is the jobbing centre for a large agricultural area, a shipping point for cotton, and has bauxite mines and numerous manufacturing industries. The city was founded about 1800.

EUGÈNE OF SAVOY (FRANÇOIS EUGENE), PRINCE (1663–1736), fifth son of Prince Eugène Maurice of Savoy-Carignano, count of Soissons, and of Olympia Mancini, niece of Cardinal Mazarin, was born in Paris on Oct. 18, 1663. Originally destined for the church, Eugène desired to enter the army, but his mother had fallen into disgrace at court, and Louis XIV. refused him a commission. This, and his mother's influence produced in him a lifelong resentment against the king. He went to Vienna, where his relative the emperor Leopold I. received him kindly, and he served with the Austrian army during the campaign of 1683 against the Turks. His courage in a cavalry fight at Petronell (7th July) and in the great battle for the relief of Vienna won for him the command of a regiment of dragoons. He was wounded at the capture of Buda (Aug. 3, 1686) and at the siege of Belgrade (1688). A decree of banishment from France was now issued against all Frenchmen who continued to serve in foreign armies. "The king will see me again," was Eugène's reply when the news was communicated to him; he continued his career in foreign service.

Prince Eugène's next employment (1689) was partly diplomatic. He was sent by Leopold to Italy with the view of securing the co-operation of the duke of Savoy with the Italian and Spanish troops. Later in 1689 he served on the Rhine and was again wounded. He returned to Italy in time for the battle of Staffarda, in which the coalition was defeated by the French marshal Catinat; but in the spring of 1691 Prince Eugène raised the siege of Coni, took possession of Carmagnola, and in the end completely defeated Catinat. He followed up his success by entering Dauphiné, where he took possession of Embrun and Gap. Eventually the further prosecution of the war was abandoned owing to the defection of the duke of Savoy, and Eugène returned to Vienna, where he received the command of the army in Hungary. Louis XIV. now secretly offered him the bâton of a marshal of France, the government of Champagne and a pension. Eugène indignantly rejected these offers and proceeded to serve against the Turks. He surprised the enemy (Sept. 11, 1697) at Zenta, on the Theiss. The victory was one of the most complete ever won by the Austrian arms. Peace was at length concluded at Karlowitz on Jan. 26, 1699.

Two years later he was again in active service in the War of the Spanish succession (*q.v.*). At the beginning of the year 1701 he was sent into Italy to oppose his old antagonist Catinat. He achieved a rapid success, crossing the mountains from Tirol into Italy in spite of almost insurmountable difficulties (*Journal d. Militärwissensch. Verein*, No. 5, 1907), forcing the French army to retire behind the Oglio, where a series of reverses led to Catinat's recall. Villeroi, Catinat's successor, ventured to attack Eugène at Chiari, and was repulsed with great loss. The French were forced to abandon the whole of the Mantuan territory and to take refuge in Cremona. By means of a stratagem, Eugène penetrated into the city during the night, at the head of 2,000 men, and though he could not hold the town, carried off Villeroi as a prisoner. The French army was then largely reinforced under the able command of Vendôme, and the campaign was ended by the sanguinary battle of Luzzara (Aug. 1, 1702) in which each party claimed the victory. The armies went into winter quarters, and Eugène returned to Vienna, where he was appointed president of the council of war. He was then sent against the insurgents in Hungary. After the collapse of the revolt, he was sent to Bavaria, where, in 1704, he made his first campaign along with Marlborough. Similarity of tastes, views and talents soon established between these two great men a rare friendship which contributed to the success of the allies. The first victory (Aug. 3, 1704) was that of Höchstadt or Blenheim (*q.v.*) where the English and imperial troops vanquished one of the finest armies that France had ever sent into Germany.

But in Eugène's absence, Vendôme, who commanded the French army in Italy, had obtained various successes against the duke of Savoy, who had once more joined Austria. The emperor recalled Eugène and sent him to Italy. After a variety of marches and counter-marches, in which both commanders displayed signal ability, the two armies met at Cassano (August 16, 1705). Prince Eugène received two severe wounds which forced him to quit the field; this accident decided the fate of the battle, and for the time suspended the prince's march towards Piedmont. Vendôme, however, was recalled, and his successor, La Feuillad, was helpless against Eugène who appeared before the entrenched camp at Turin, which place the French were now besieging with an army 80,000 strong. Prince Eugène had only 30,000 men; but on Sept. 7, 1706 he attacked the French army in its entrenchments and gained a victory which decided the fate of Italy. In the heat of the battle Eugène received a wound, and was thrown from his horse. He was rewarded by the government of the Milanese, of which he took possession with great pomp on April 16, 1707. He was also made lieutenant-general to the emperor Joseph I. The attempt which he made against Toulon in the course of the same year failed completely. The prince now returned to Vienna, where he was received with great enthusiasm. The Emperor immediately despatched Eugène to Holland, and to the different courts of Germany, in order to forward the necessary preparations for the campaign of the following year, 1708 (*see* SPANISH SUCCESSION, WAR OF THE).

Early in the spring of 1708 the prince assumed the command of the German army in Flanders. The campaign was opened by the victory of Oudenarde (*q.v.*). The French immediately abandoned the Low Countries, and made no attempt to prevent Eugène's army, covered by that of Marlborough, making the siege of Lille. After the capture of Lille, Eugène and Marlborough proceeded to the Hague, and negotiations were opened for peace, but proved fruitless. In 1709 France placed Marshal Villars, her best living general, in command. The bloody victory of Malplaquet (*q.v.*), was so dearly bought that the allies broke off the campaign and went into winter quarters. Eugène was sent on a mission to the king of Prussia. He then returned to Flanders, where, excepting the capture of Douai, Bethune and Aire, the campaign of 1710 presented nothing remarkable. On the death of the emperor Joseph I. in April 1711, Prince Eugène, in concert with the empress, sought to secure the crown to the archduke, who afterwards ascended the imperial throne under the name of Charles VI. In the same year Marlborough fell from favour with Queen Anne. Prince Eugène immediately repaired to London, in the hope of

restoring Marlborough's credit and re-attaching England to the coalition. The mission failed, and the emperor had to make the campaign of 1712 with the aid of the Dutch alone. Nevertheless, Eugène resolved, at whatever cost, to penetrate into Champagne; and began operations by making himself master of Quesnoy. But the Dutch, having been surprised and beaten in the lines of Denain, he was obliged to raise the siege of Landrecies, and to abandon the project of invading France. Abandoned first by England and then by Holland, the emperor still wished to continue the war in Germany; but Eugène was unable to relieve either Landau or Freiburg, both of which capitulated. Seeing the Empire thus laid open to the armies of France, and the Austrian hereditary states exposed to invasion, the prince counselled peace. He was entrusted with full powers to negotiate and concluded peace at Rastadt on March 6, 1714. After his return to Vienna, Eugène exchanged the government of the Milanese for that of the Austrian Netherlands.

In the spring of 1716 the emperor having concluded an offensive alliance with Venice against Turkey, appointed Eugène to command the army of Hungary; and at Peterwardein he gained (Aug. 5, 1716) a signal victory over a Turkish army of more than twice his own strength. The pope sent the victorious general the consecrated hat and sword which the court of Rome was accustomed to bestow upon those who had triumphed over the infidels. Eugène won another victory in this campaign at Temesvár. In 1717, Eugène laid siege to Belgrade, where he had to deal with the garrison of 30,000 men and a relieving army of 200,000, while his own force was only about 40,000 strong. On the morning of Aug. 16, 1717 he ordered a general attack, which resulted in the total defeat of the enemy with enormous loss, and in the capitulation of the city six days afterwards. The prince was wounded, for the thirteenth time. The popular song "Prinz Eugen, der edle Ritter," commemorates the victory of Belgrade. In 1718, after some fruitless negotiations, he again took the field, but the treaty of Passarowitz (July 21, 1718) concluded hostilities at the moment when the prince had well-founded hopes even of reaching Constantinople, and dictating a peace on the shores of the Bosporus.

As the government of the Netherlands, up to 1724 held by Eugène, had now been bestowed on a sister of the emperor, the prince was appointed vicar-general of Italy, with a pension of 300,000 florins. His personal relations with the emperor were not so cordial as before, and he suffered from the intrigues of the Spanish or anti-German party. On discovering the conspiracy of Tedeschi and Nimptsch in 1719, the prince threatened to lay down all his offices if the conspirators were not punished. During the years of peace between the Treaty of Passarowitz and the War of the Polish Succession, Eugène occupied himself with the arts and with literature, and corresponded with many of the most eminent men in Europe. Austria attacked France against the advice of Eugène (1734). Nevertheless, he was appointed to command the army destined to act upon the Rhine; if it could not prevent the capture of Philipsburg after a long siege, it at least prevented the enemy from entering Bavaria. Eugène, who was now 71, no longer possessed his former vigour, and he welcomed the peace concluded on Oct. 3, 1735. He died at Vienna on April 21, 1736, leaving an immense inheritance to his niece, the princess Victoria of Savoy.

Of a character cold and severe, Prince Eugène had almost no other passion than that of glory. He died unmarried, and seemed so little susceptible to female influence that he was styled a Mars without a Venus. That he was one of the great captains of history is universally admitted. The special characteristics of his generalship were imagination, fiery energy and a tactical resolution which was rare indeed in the 18th century. His almost invariable success raised the reputation of the Austrian army to a point which it never reached either before or since his day. War was with him a passion. Always on the march, in camps, or on the field of battle during more than fifty years, and under the reigns of three emperors, he had scarcely passed two years together without fighting. Yet his political activity was not inconsiderable and his advice was always sound and well-considered; while in his government of the Netherlands, which he exercised through the marquis de Prié, he set himself resolutely to oppose the many wild schemes, such as Law's Mississippi project, in which the times were so fertile. He took keen interest in literature and art. His palace in Vienna, and the Belvedere near that city, his library, and his collection of paintings were renowned.

EUGENE, a city of western Oregon, U.S.A., at the head of navigation on the Willamette river, 125m. S. of Portland; the county seat of Lane county and the seat of the State university. It is at the intersection of Federal highways 28 and 99; is served by the Oregon Electric and the Southern Pacific railways; and has a municipal airport. The population in 1920 was 10,593 (94% native white). The city lies at the edge of a broad fertile prairie, at the foot of a ridge of low hills, with the peaks of the Coast Range visible in the distance. It is the trading and shipping centre for the agricultural, stock-raising and lumbering territory extending from the Cascades to the coast, and has manufacturing industries which in 1925 produced goods valued at $3,906,013. The University of Oregon and the Eugene Bible university (Disciples, established in 1895) are located here. There is fine fishing at many points near the city. Eugene was settled in 1854 and incorporated in 1864.

EUGENICS, a word coined by the late Sir Francis Galton in 1885 and derived from the Greek εὐγενής, "well born." The latest definition of the term given by Galton runs as follows: "Eugenics is the study of agencies under social control which may improve or impair the racial qualities of future generations either physically or mentally." It is well established that men are what they are, partly on account of the inborn or racial qualities derived from their parents, and partly on account of their surroundings. In the fashioning of men both the nature of the material and of the workmanship applied to it affect the final product. The word eugenics is used to cover any proposals or plans for the improvement of the racial qualities of human beings. Therefore eugenic proposals aim at social improvement. They differ fundamentally from other projects having the same object in that they are concerned with the improvement of the human material and not of the surroundings. But they are not alternative to these projects. Improvement of the material and improvement of the surroundings should go on at the same time. A good result will only be achieved where good workmanship is applied to good material. While the word eugenics is used to mean plans for racial improvement, it is also used for the study of the part played by racial qualities in making men what they are. Galton introduced the word "study" into his definition though the definition as a whole makes it apparent that he was thinking of such studies as would be the foundation of plans. There is a distinction between the pure study of natural phenomena in and for itself and the study of how to apply the knowledge so gained for certain purposes. Whether or not eugenics is properly held to be a pure as well as an applied science, it remains true that the necessary knowledge must be available before any application can be attempted. It is in fact a mere matter of terminology whether we speak of a pure science of eugenics and also of an applied science of eugenics, or whether we regard eugenics wholly as an applied science. In any case those interested in eugenics must acquaint themselves with the results achieved by workers in certain fields of pure science and to them we turn.

Eugenic proposals must be based in the first place upon such knowledge as we possess of the part played by inborn qualities in making men what they are. It is evident that they do play some part. In the United States of America the surroundings of negroes are much the same as those of white men and yet they are sharply marked off from one another owing, it is to be inferred, to differences in racial qualities. We may study identical twins who

are derived from the division of a single fertilized cell at an early stage of development. Identical twins have therefore the same inherited qualities and differences between them must be due to differences in their surroundings. Again we may study the inmates of orphanages. They form the reverse case. They are no more alike in inborn qualities than persons chosen at random from the public at large and they have been subjected to the same environment for varying periods of years. Other methods of approach are available. As a result of such studies we reach the general conclusion that the differences between men are to no small extent the result of inborn differences. This conclusion is founded upon the facts that identical twins remain closely alike in spite of diversity of experience, that orphan children tend only slightly to grow alike in spite of similarity of experience and upon other evidence. This statement should not be misunderstood. Some differences between men are wholly the result of different experiences. Thus a child may be rendered mentally deficient by an accident at birth. But at least three quarters of all mentally deficient children have mentally deficient relatives and may be supposed to have inherited the condition. What the statement means is that, when we investigate the causes of the innumerable differences between men in respect of intelligence, temperament character, health, physique and other characteristics, which we observe between those whom we meet, we find that, while almost any kind of difference can be wholly produced by differences in the environment, most differences in part, many in large part, are due to inherited differences. Inborn characters are thus of great importance and they are derived from the parents. The study of the precise manner in which they are derived is the study of heredity. This study has been greatly advanced in the present century and we now understand the mechanism of inheritance. While the recently acquired knowledge is of great importance, when we are concerned with particular problems, for the purposes of a general review it merely explains what was known before. It has long been common knowledge that like tends to produce like, that tall parents tend to have tall children, able parents able children, and so on. We now know how this comes about. We have therefore the position that those who differ from their fellow men in exhibiting greater ability or stature than the average do so mainly because of the possession of certain inborn qualities and that the offspring of such persons will more often than not be abler or taller than the average.

It is to students of certain branches of biology that we look for knowledge of matters such as those we have just discussed. This knowledge is not sufficient for the making of proposals to improve racial qualities. It is necessary to have information upon other subjects, which lie within the field of sociology or social science, and among these subjects that which first claims attention is the distribution of racial qualities within the population. Men differ profoundly in respect of their inborn endowments and it might be that all those, or the majority of those, endowed with ability above a certain level, or with physical strength above a certain standard, are to be found in certain areas, in certain occupations or in certain classes. On the other hand inborn qualities might be so distributed that the average representative of those following each occupation, of the members of each social class or of the inhabitants of every locality had approximately similar endowments. Little is known as yet regarding the distribution of physical qualities though there is reason to believe that the average miner and agricultural labourer are physically stronger than the average working man. More is known about the distribution of those inborn mental qualities which can be measured by the use of intelligence tests. These tests have been widely used of late in Great Britain and America, and many investigators have employed them to throw light upon the distribution of intelligence within the population. In 1912 13,595 school children between the ages of 11 and 13 were tested in Northumberland and the intelligence quotient of each child ascertained. The intelligence quotient is independent of age and an intelligence quotient of more or less than 100 is indicative of an intelligence above or below normal. The occupations of the fathers were known and the children may be classified by these occupations.

Occupations of Fathers and Intelligence of Children in Northumberland

Occupations of Fathers	*Average I.Q. of Children*
Professional	112·2
Managerial	110·0
Higher commercial	109·3
Army, navy, police, postmen	105·5
Shopkeeping	105·0
Engineering	102·9
Foremen	102·7
Building	102·0
Metal workers, shipbuilders	100·9
Miscellaneous industrial workers	100·6
Miners and quarrymen	97·6
Agriculture (all classes)	97·6
Low grade occupations	96·0

It will be noticed that in general the higher economic or social position of the parents the higher the intelligence quotient of the children. Numerous other investigations point to the same conclusion. There are three points to be observed. Firstly, it is only what is to be expected from a knowledge of the social conditions. There is a mechanism which, working through free places, scholarships and the opening generally of chances to bright children, results in a sifting out of the abler among each generation who find a place in a higher economic class than that of which their parents were members. Since the children of those thus promoted will tend to inherit the intelligence of their parents, it would be astonishing if the members of the higher economic classes were not more intelligent on the average than the members of the lower economic classes. Secondly, it should be observed that the only established differences between the average representative of the social classes are in respect of that aspect of intelligence which can be measured by tests. Social and occupational groups may differ in respect of temperamental and emotional qualities and also in respect of physical endowment. We may suspect such differences because the temperament and physique of a man is not without influence in determining his place in society; but we have no definite information on this subject. Thirdly, it does not follow that, because the members of a certain social class are on the average more highly endowed with some inborn quality, they are better in any ethical sense than members of other classes.

It is also necessary to study the contribution to the next generation made by persons with different inborn qualities. In this manner light can be thrown upon the problem whether the racial qualities of the population are changing. The direct method is to select those known to be endowed with qualities different from those possessed by the average number of the population and to ascertain whether the rate of contribution to the next generation made by the former is greater or less than that made by the latter. Many investigations of this kind have been made especially in the United States. It has been repeatedly shown that those with more than average ability contribute less than the average number of children to the next generation. It has not been proved that the mental defectives as a class contribute more than their share. This method can as a rule only be employed in enquiries of limited scope. The problem can be approached indirectly by the employment of statistics such as are collected by the census authorities. The questions asked at the English Census of 1911 were so framed that the families could be allocated to social groups according to the social class to which the head of the family belonged. Eight groups were set up. The wage earners in the textile, mining and agricultural industries were placed in classes VI., VII. and VIII. respectively. The rest of the population was distributed between five classes as follows: class I., upper and middle; class II., intermediate; class III., skilled; class IV., intermediate; class V., unskilled. The results of so doing are set out in the table on next page.

The important figures are those giving the number of children surviving per 100 families in each class and it will be seen that the lower the social class the larger the number of surviving children. As we have seen there is evidence that the higher the class the greater is the average degree of intelligence. From this it is to be deduced that the changes in progress in the endowment of the population as a whole in respect of intelligence are in the direction of a lowering of the level. Since we do not know

England and Wales, 1911. Marriages where the wife had not attained the age of 45 years at census. Total and effective fertility and child mortality classified by social status (as indicated by husband's occupation) for all durations of marriage.

	Social class.							
	1.	2.	3.	4.	5.	6.	7.	8.
Children born per 100 families	190	241	279	287	337	238	358	327
Children dead per 1,000 born	116	147	167	173	206	200	213	131
Children surviving per 100 families	168	205	232	237	268	191	282	284

whether these social classes differ in their temperamental and physical endowment, it is not possible to say whether this process is also bringing about changes in the average endowment of the population in these respects.

Lastly before plans for racial improvement can be made it is necessary to gain some knowledge of the factors which influence the size of family. This is so because, while most proposals may contemplate prohibition of reproduction by certain persons, some proposals aim at stimulating or discouraging reproduction in certain groups. It is now generally agreed that the most important immediate cause of smaller families in certain classes is the greater use of family limitation. But the enquiry must be pushed further back and an attempt made to ascertain why family limitation is more employed by some classes than others. For this there are many reasons. The knowledge of methods of family limitation is not equally spread among all classes. Wage earners receive their maximum income early in life and are therefore not under any inducement to postpone marriage as are the professional classes who may only reach their maximum income when 40 years of age or more. The education of children is more of an expense to professional parents than to working-class parents and the children are less of a support to their parents in old age among the professional than among the working classes. These and other reasons may account for the different rates of reproduction between the classes. Unless the reasons for these conditions are understood effective proposals cannot be made for changing the situation. Again, it cannot be foretold what effects proposals made with quite other immediate objects are likely to have. Thus family endowment is widely advocated in order to alleviate poverty. It is very desirable to be able to estimate the effect of such a measure upon the size of such families.

On the basis of knowledge of this nature plans for racial improvement may be made. Stress is at times laid on evidence of racial deterioration and proposals often have as their immediate object the prevention of race deterioration. It is necessary to emphasize the urgent need and abundant opportunity for racial improvement. There are large numbers of persons who by reason of defective inborn endowment are unable to lead full lives and are a burden to themselves and others. Thus in 1925 the number of children in England and Wales certified as mentally defective amounted to about 33,000 or 6·7 per 1,000 of children in average attendance at public elementary schools. It is generally acknowledged that all mentally defective children have not been certified and that the proportion probably reaches 10 per 1,000. Poverty, crime, drunkenness, disease and other social problems are intensified by defective inborn equipment. There is ample opportunity because there are persons who are generously endowed both physically and mentally, and it is possible to bring up the average endowment of the race to somewhere near their level. Human history is largely the story of attempts by man to bring his surroundings under control. But if he wishes to bring his destiny under control he must turn his attention to the control of human material as well as to the control of human surroundings. He must attempt to govern his own racial evolution. Attempts to do this are in line with all that inspires man to improve his surroundings. They do, however, depart somewhat from other proposals in that of necessity they contemplate restrictions upon the very intimate human relationship of marriage. But it may be pointed out that this relationship is already directly affected by restrictions upon marriage by persons below a certain age or between persons within certain degrees of blood relationship and is also indirectly affected by many kinds of social legislation such, for instance, as that concerning housing or taxation. Eugenic proposals therefore contemplate the extension of an existing principle rather than the introduction of any new principle in the field of social organization.

Eugenic proposals aim at (1) the prevention of reproduction by persons of definitely defective types and (2) the encouragement of reproduction by persons of sound stock. (1) The marriage of defective persons can be prohibited. The marriage of mentally defective persons is prohibited in Russia. Again in several of the United States of America marriage is prohibited on account of one or more of the following conditions: insanity, feeble mindedness, epilepsy, criminality and alcoholism. There is no such prohibition in Great Britain. Prohibition of marriage may not prevent reproduction, especially by the mentally defective, and therefore segregation and sterilization are sometimes recommended. Segregation is now practised to some extent in all civilized countries to safeguard the defectives and the public, but not with the deliberate intention to prevent reproduction. Over 50,000 mentally defective persons are now segregated or under supervision in Great Britain. But segregation is expensive and is not likely to be applied to the less seriously afflicted who can wholly or partly support themselves. Therefore sterilization is advocated in some quarters. In 1926 sterilization laws had been enacted in 23 of the 48 United States, and over 6,000 operations had been performed. It has also been proposed that as a preliminary to the issue of a marriage licence certificates should be exchanged between the parties concerned setting out certain facts relating to family and personal history. When the licence is issued an approved statement laying down in simple language what is known of the laws of inheritance might be handed to the parties. Legislation of the latter kind would not be restrictive but it might educate young persons in regard to their responsibilities and induce certain persons to refrain from reproduction. (2) Proposals for encouraging reproduction among the fit by legal action are mainly confined to amending the system of taxation so that the amounts levied on married couples with children should be materially less than the amounts levied on the unmarried and the childless. It is also hoped to rouse among the fit a sense of their responsibility as bearers of desirable traits which should lead them to desire to perpetuate these traits. It will be observed that the action so far taken and the proposals most widely advocated aim at preventing reproduction among the unfit rather than encouraging reproduction among the fit. Regarding proposals of the former kind three points may be noticed. It is not difficult to obtain a general consensus of opinion as to what constitutes unfitness though opinions may differ as to what degree of unfitness should form a bar to marriage. Secondly there is abundant evidence that desirable qualities are not especially associated with certain undesirable traits. It is not the case that genius is associated with insanity or mental ability with physical debility. Therefore fear that the cutting off of defective persons would tell against the production of genius is baseless. Such cutting off would result in a raising of the general level of the racial qualities of the population and would increase the chances of the birth of a genius. Thirdly it can be shown that the prevention of reproduction by the unfit would be effective within a relatively short time. This may be illustrated for mental defect. If it is supposed that mental defect is inherited as a recessive quality and that it is scattered at random among the population, it can be demonstrated that, starting with a frequency of 100 defectives per 10,000 of the population, it would be reduced by prohibition of marriage among those showing the defect to 82·6 per 10,000 in one generation, to 69·4 in the next generation and to 59·2 in the third generation. But the assumptions upon which the calculation is based are very unfavourable. It is almost certain that restriction of reproduction would reduce the amount of mental defect with much greater rapidity. It is most unlikely, for instance, that mental defect is equally distributed throughout the population and, to the extent to which it is concentrated in certain strains, the swifter will be

the reduction of the incidence of defect. So far as proposals to encourage reproduction are concerned, it is evident that it is much more difficult to define the fit than the unfit. Such proposals usually go no further than aiming at the removal of burdens so far as possible which rest upon those of sound stock and discourage them from contributing their share to the next generation.

During the present century organizations have been founded to promote research into eugenic problems and to conduct propaganda in favour of eugenic proposals. Much of the research work upon which eugenic proposals must be founded lies in the field of established sciences. There are, however, other fields of research. Such is the case, for instance, with regard to investigations into the distribution of inherited qualities within the population. Research institutes in England and America have been founded to investigate these and other problems. The Eugenics Record Office, of which Dr. C. B. Davenport is head, was founded in 1910. It is a section of the Department of Genetics of the Carnegie Institution of Washington and is situated at Cold Spring Harbour (N.Y.). Sir Francis Galton (d. 1911) founded by a bequest in his will a chair of Eugenics at University college, London. Professor Karl Pearson was appointed to this chair.

It is now becoming recognized that, valuable as these research institutions may be, they cannot collect some of the most important data without Government assistance. The Government could conduct periodically a census of the mental and physical qualities of all school children. It might be advisable to set up a special Government department to advise upon or conduct the collection of this information. Such a department has been founded in Sweden. In 1922 the Swedish State Institute of Race Biology was set up at Uppsala. It is controlled by a council of six members nominated by the Crown. The institute is primarily concerned with research. It is contemplated, however, that it may be called upon to advise as to legislation. Societies for the promotion of eugenic proposals exist in every country. The aim of these societies is to popularize eugenics by placing before the public concrete eugenic proposals.

EUGÉNIE (MARIE-EUGÉNIE-IGNACE-AUGUSTINE DE MONTIJO) (1826–1920), wife of Napoleon III., emperor of the French, daughter of Don Cipriano Guzman y Porto Carrero, count of Teba, subsequently count of Montijo and grandee of Spain, was born at Granada on May 5, 1826. Her mother was a daughter of William Kirkpatrick, United States consul at Malaga, a Scotsman by birth and an American by nationality. Her childhood was spent in Madrid, but after 1834 she lived with her mother and sister chiefly in Paris, where she was educated, like so many French girls of good family, in the convent of the Sacré Coeur. When Louis Napoleon became president of the republic she appeared frequently with her mother at the balls given by the prince president at the Elysées. In Nov. 1852 mother and daughter were invited to Fontainebleau, and in the picturesque hunting parties the beautiful young Spaniard, who showed herself an expert horsewoman, was greatly admired. Three weeks later, on Dec. 2, the Empire was formally proclaimed, and during a series of fêtes at Compiègne, which lasted eleven days (Dec. 19–30), the emperor became more and more enamoured. Early in January he made a formal proposal of marriage. In a speech from the throne on Jan. 22, he formally announced his engagement, and justified what was considered a mésalliance. The marriage was celebrated with great pomp at Notre Dame on Jan. 30, 1853. On March 16, 1856 the empress gave birth to a son, who received the title of prince imperial. She was the mirror of fashion for all Europe. By her beauty, elegance and charm of manner she contributed largely to the brilliancy of the imperial régime, and when the end came, she was, as the official *Enquête* made by her enemies proved, one of the very few who showed calmness and courage in face of the rising tide of revolution. The empress acted three times as regent during the absence of the emperor,—in 1859, 1865 and 1870,—and she was generally consulted on important questions. When the emperor vacillated between two lines of policy she generally urged on him the bolder course; she deprecated everything tending to diminish the temporal power of the papacy, and she disapproved of the emperor's liberal policy at the close of his reign. On the collapse of the Empire she fled to England, and settled with the emperor and her son at Chislehurst. After the emperor's death she removed to Farnborough, where she built a mausoleum to his memory. The ex-Empress found a faithful friend in Queen Victoria, whose own family bereavements deepened her sympathy with Eugénie. In 1879 her son was killed in the Zulu War, and in the following year she visited the spot and brought back the body to be interred beside that of his father. At Farnborough, and in a villa she built at Cap Martin on the Riviera, she continued to live in retirement, following closely the course of events, but abstaining from all interference in French politics. She died in Madrid on July 11, 1920, while on a visit to the queen of Spain, who was her favourite god-daughter.

EUGENIUS I., pope from 654 to 657. Elected on the banishment of Martin I. by the emperor Constans II., and at the height of the Monothelite crisis, he showed greater deference than his predecessor to the emperor's wishes, and made no public stand against the patriarchs of Constantinople, though he held no communication with them.

EUGENIUS II., pope, a native of Rome, succeeded Pascal I. in 824. He was the candidate of the nobles, and the clerical faction brought forward a competitor. But the monk Wala, the representative of the emperor Lothair, succeeded in securing the election of Eugenius. Lothair, however, took advantage of this opportunity to redress many abuses in the papal administration, to vest the election of the pope in the nobles, and to confirm the statute that no pope should be consecrated until his election had the approval of the emperor. A council which assembled at Rome passed enactments for the restoration of church discipline, took measures for the foundation of schools and chapters, and decided against priests wearing secular dress or engaging in secular occupations. Eugenius died in 827.

EUGENIUS III. (Bernardo Paganelli), pope from Feb. 15, 1145 to July 8, 1153, native of Pisa, was abbot of the Cistercian monastery of St. Anastasius at Rome when he succeeded Lucius II. Immediately after his election, the Roman senators demanded the pope's renunciation of temporal power. He refused and fled to Farfa, where he was consecrated. By treaty of Dec. 1145 he recognized the republic under his suzerainty, substituted a papal prefect for the "patrician" and returned to Rome. The celebrated schismatic, Arnold of Brescia, however, again headed the party opposed to the temporal power of the papacy, re-established the patricianate, and forced the pope to leave Rome. In Jan. 1147 Eugenius journeyed to France to further preparations for the Second Crusade and to seek aid in the constant feuds at Rome. After holding synods at Paris, Reims and Trier, he returned to Italy in June 1148, excommunicated Arnold of Brescia in a synod at Cremona, and thenceforth endeavoured to recover his see. Negotiations between Frederick Barbarossa and the Romans enabled Eugenius to return to Rome in Dec. 1152, where he died in the following July. Eugenius exhibited the stoic virtues of monasticism and was reverenced for his personal character. His tomb in St. Peter's acquired fame for miraculous cures, and he was pronounced blessed by Pius IX. in 1872.

See his letters in Migne, *Patrol. Lat.*, vols. 106, 180, 182, and in *Bibliothèque de l'École des Chartes*, vol. 57 (Paris, 1896); the life by Cardinal Boso in J. M. Watterich, *Pontif. Roman. vitae*, vol. 2; and the life by John of Salisbury in *Monumenta Germaniae historica. Scriptores*, vol. 20; J. Langen, *Gesch. der römischen Kirche von Gregor VII. bis Innocenz III.* (Bonn, 1893); F. Gregorovius, *Rome in the Middle Ages*, vol. 4, trans. by G. W. Hamilton (1900–02); Hefele, *Conciliengeschichte*, Bd. 5, 2nd ed.; Jaffé-Wattenbach, *Regesta pontif. Roman.* (1885–88); M. Jocham, *Gesch. des Lebens u. der Verehrung des seligen Papstes Eugen III.* (Augsburg, 1873); B. Kugler, *Analekten zur Gesch. des zweiten Kreuzzugs* (Tübingen, 1878–83).

EUGENIUS IV. (Gabriel Condulmieri or Coldumario), pope March 3, 1431 to Feb. 23, 1447, was born at Venice. He entered the Celestine order, and his uncle, Gregory XII., appointed him bishop of Siena, papal treasurer, protonotary, cardinal-priest of S. Marco e St. Clemente, and later cardinal-priest

of S. Maria in Trastevere. The most important feature of Eugenius's pontificate was the struggle between pope and council. In July 1431 his legate opened the council of Basle but, distrustful of its purposes and moved by the small attendance, the pope issued a bull in Dec. 1431, dissolving the council. The council refused to dissolve, renewed the revolutionary resolutions by which the council of Constance had been declared superior to the pope, and cited Eugenius to appear at Basle. A compromise was arranged by Sigismund, by which the pope recalled the bull of dissolution, and, reserving the rights of the Holy See, acknowledged the council as oecumenical (Dec. 15, 1433). The struggle with the council broke out anew. Eugenius at length convened a rival council at Ferrara on Jan. 8, 1438 and excommunicated the prelates assembled at Basel. The latter then formally deposed him as a heretic, and in Nov. 1439 elected Amadeus VIII., duke of Savoy, antipope under the title of Felix V. The conduct of France and Germany seemed to warrant this action, for Charles VII. had introduced the decrees of the council of Basel, with slight changes, into the former country through the pragmatic sanction of Bourges (July 7, 1438), and the diet of Mainz had deprived the pope of most of his rights in the latter country (March 26, 1439). At Florence, whither the council of Ferrara had been transferred, a temporary union with the Greeks was effected in July 1439. Eugenius signed an agreement with the Armenians on Nov. 22, 1439, and with a part of the Jacobites in 1443; and in 1445 he received the Nestorians and Maronites. He tried to stem the Turkish advance, pledging one-fifth of the papal income to the unfortunate crusade of 1443. Meanwhile the adviser of his rival, Felix V., made peace with him in 1442. The pope's recognition of the claims to Naples of King Alphonso of Aragon withdrew the last important support from the council of Basle, and enabled him to enter Rome in Sept. 1443, after an exile of nearly ten years. His victory over the council and his efforts in behalf of church unity contributed greatly to break down the conciliar movement and restore the papacy to the position it had held before the Great Schism. Eugenius laboured to reform the monastic orders, and was a devotee of art and learning. He died on Feb. 23, 1447.

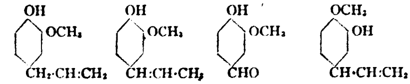
Sixtus IV.*, ed. by K. Hayn (Cologne, 1896).

EUGENOL, an odoriferous principle, the chief constituent of oil of cloves, and occurring in many other essential oils. Structurally it is *allyl guaiacol*, $C_{10}H_{12}O_2$. It can be synthetically prepared by the reduction of coniferyl alcohol,

$$(HO)(CH_3O)C_6H_3{\cdot}CH{:}CH{\cdot}CH_2OH,$$

which occurs in combination with glucose in the glucoside coniferin, $C_{16}H_{22}O_8$. It is a colourless oil boiling at 247° C, and having a spicy odour. By the action of alkalis it is converted into iso-eugenol, which on oxidation yields vanillin, the odorous principle of vanilla (*q.v.*). This transformation of allyl phenols into propenyl phenols is very general. The amount of eugenol in oil of cloves can be estimated by acetylation in presence of pyridine or by absorption in normal potassium hydroxide solution in a cassia flask. *Chavibetol*, an isomeride of eugenol, occurs in the ethereal oil obtained from *Piper betle*.

The structural relations are:



Eugenol Iso-eugenol Vanillin Chavibetol

EUGIPPIUS or **EUGYPIUS** (*c.* 455–*c.* 538), abbot of Lucullanum near Naples, was born at Carthage and studied in Rome under St. Severin, whose biography he wrote. He also compiled *Thesaurus Augustinianeus*. His *opera* are edited in the *Corpus Script. Eccl. Lat.* vol. ix. and in Migne's *Patrol. Lat.* vol. 62.

EUHEMERUS (EUEMERUS, EVEMERUS) (*fl. c.* 300 B.C.), Greek mythographer, born at Messana, Sicily (others say at Chios, Tegea or Messene in Peloponnese), and lived at the court of Cassander. He is chiefly known by his *Sacred History* (Ἱερὰ ἀναγραφή), a philosophical romance, based upon archaic inscriptions which he claimed to have found during his travels in Greece. In this work he for the first time systematized an old Oriental (perhaps Phoenician) method of interpreting the popular myths, asserting that the gods of popular worship had been originally heroes and conquerors. The word "euhemeristic" is consequently applied to such explanations of primitive myths. Euhemerus was a firm upholder of the Cyrenaic philosophy, and by many ancient writers he was regarded as an atheist. His work exists only in a few fragments of the Latin trans. by Ennius.

See Raymond de Block, *Évhémère, son livre et sa doctrine* (Mons, 1876); G. N. Némethy, *Euhemeri relliquiae* (Budapest, 1889); Ganss, *Quaestiones Euhemereae* (Kempen, 1860); O. Sieroka, *De Euhemero* (1869); Susemihl, *Gesch. der griech. Litteratur in der Alexandrinerzeit*, vol. i. (Leipzig, 1891).

EULALIUS (d. 423), anti-pope in 418 in opposition to Boniface I. (*q.v.*). The rivalry led to the first interference of the temporal authorities in papal elections, and Eulalius was ultimately banished to Campania.

See *Liber Pontificalis*, vol. i. ed. Duchesne (Paris, 1886) and Jaffé, *Regesta Romanorum Pontificum*, vol. i. (Leipzig, 1885).

EULENBURG, BOTHO, GRAF ZU (1831–1912), Prussian statesman, son of Botho Heinrich, Graf zu Eulenburg-Wicken, president of the chamber of deputies 1855–58, was born at Wicken on July 31, 1831. He held various administrative positions before he succeeded, in 1878, his cousin Count Friedrich Eulenburg (*q.v.*) as minister of the interior. He resigned in 1881. In 1892 he was prime minister of Prussia for a few months, returning to the ministry of the interior in August. In 1894 he came into conflict with the imperial chancellor Caprivi (*q.v.*) over the bill for the amendment of the criminal code. In October, the emperor William II., who was on a visit to the Eulenburgs at their country seat, suddenly dismissed the chancellor. Eulenburg was also dismissed. He entered the Prussian Upper House in 1899. Eulenburg died at Berlin on Nov. 5, 1912.

EULENBURG, FRIEDRICH, GRAF ZU (1815–1881), Prussian statesman, was born at Königsberg on June 29, 1815. He entered the diplomatic service in 1852, and, after holding various European appointments, was sent on a mission to the Far East, where he concluded commercial treaties with Japan (Jan. 24, 1861) and with China (Sept. 2, 1861). On his return he became minister of the interior, and supported Bismarck in his insistence on the necessity of expenditure on armaments in Prussia. After 1866 he organized relations with the newly-acquired provinces of Prussia, Hanover, Hesse-Cassel, Frankfurt, Schleswig-Holstein duchies and Lauenburg. He resigned in 1878 when Bismarck refused to sanction his proposals for town and parish administration. Count Eulenburg died on June 2, 1881, at Berlin-Schöneberg.

See his *Ostasien 1860 bis 1862 in Briefen*, edit. Count Philipp zu Hertefeld-Eulenburg (1900), and his *Zehn Jahre innere Politik 1862 bis 1872* (1872).

EULENBURG-HERTEFELD, PHILIP ZU, PRINCE AND COUNT (1847–1921), German diplomat, was born Feb. 12, 1847 in Königsberg. He fought in the campaigns of 1866 and 1870–71 with the *Gardes du Corps*, and in the latter campaign won the iron cross for valour. But his heart was not in the fighting traditions of his family, and in 1877 he gladly abandoned the military for the diplomatic service. Appointed in 1881 third secretary at the German embassy in Paris, where he became the intimate friend of the later chancellor, Prince Bülow, Eulenburg was transferred a year later to Munich. From 1888 he was minister to the grand ducal court at Oldenburg; then in 1890 was promoted to Stuttgart, but in the same year was sent to Munich. In 1893 the emperor offered him the choice of the ambassadorships at London, Paris or Vienna. Eulenburg chose the latter post, where he remained until his resignation from the service in 1902 owing to continued ill-health. Afterwards he lived in retirement—broken

only by his trial in 1908 on charges of homo-sexuality—at his castle of Liebensberg until his death on Sept. 17, 1921.

For more than 30 years the intimate friend and trusted adviser of the emperor, William II., Eulenburg might well have aspired to the highest office in the State. Indeed, in the summer of 1894, he was openly spoken of as Hohenlohe's successor in the chancellorship, but he lacked both the political ambition and physical strength that would have enabled him to grasp the prize. Instead, he was instrumental in securing it for his friend Prince Bülow. Although his influence was not openly perceptible, Eulenburg during the first half of the Emperor William II.'s reign was one of the powers behind the throne in Germany. Alone among the Kaiser's immediate entourage, Eulenburg perceived the dangers of the "new course" along which that monarch was guiding Germany. And he alone had the courage to warn his imperial friend of the impending disaster. A wit and poet, a musician and architect, an able diplomat and brilliant *causeur*, Eulenburg was amongst the most interesting and most gifted personalities in the Germany of the late 90's and early years of the present century.

Bibliography.—He wrote a volume of reminiscences, mainly of his early life and the Bismarck family, which was posthumously published under the title of *Aus 50 Jahren* (1923). His biography, in great part an attempted vindication of his moral character, was written by his friend and literary executor Prof. J. Haller under the title *Aus dem Leben des Fürsten Philipp zu Eulenburg-Hertefeld* (1924).
(I. F. D. M.)

EULENSPIEGEL (Ulenspiegel), **TILL,** the name of a popular German figure, and the title of a German chapbook of the beginning of the 16th century. The oldest extant text of the book was printed at Strasbourg in 1515 (*Ein kurtzweilig lesen von Dyl Vlenspiegel geboren vss dem land zu Brunsswick*), and is in High German, but the original was undoubtedly Low Saxon. Its hero, Till Eulenspiegel or Ulenspiegel, the son of a peasant, was born at Kneitlingen in Brunswick at the end of the 13th or at the beginning of the 14th century and died, according to tradition, at Mölln near Lübeck in 1350. He is locally associated with the Low German area extending from Magdeburg to Hanover, and from Lüneburg to the Harz Mountains. The jests and practical jokes ascribed to him were collected—if we may believe a statement in one of the old prints—as early as 1483. He is the wily peasant who exercises his wit and roguery on the tradespeople of the towns, above all, on the innkeepers; but priests, noblemen, even princes, are also his victims. His jests are often pointless, more often brutal; he indulges, when opportunity offers, in scurrility and obscenity. The satire of the chapbook turns on class distinctions, and it might be described as the retaliation of the peasant on the townsman who in the 14th and 15th centuries had begun to look down upon the country boor as his inferior. *Eulenspiegel* was early translated into Dutch, French, English, Latin, Danish, Swedish, Bohemian and Polish. In England, "Howleglas" (Scottish, *Holliglas*) was long a familiar figure; his jests were adapted to English conditions, and appropriated in the collections associated with Robin Goodfellow, Scogan and others. Ben Jonson refers to him as "Howleglass" and "Ulenspiegel" in his *Masque of the Fortunate Isles, Poetaster, Alchemist* and *Sad Shepherd.*

Bibliography.—The Strasbourg edition of 1515 (British Museum) has been reprinted by H. Knust in the *Neudrucke deutscher Litteraturwerke des 16. und 17. Jahrh.* No. 55–56 (1885) and by E. Schroeder (1911); that of 1519 by J. M. Lappenberg (1854). Some ten further editions appeared in the first half of the 16th century at Cologne, Erfurt, Strasbourg and Augsburg. Johann Fischart published an adaptation in verse, *Der Eulenspiegel Reimensweiss* (Frankfurt, 1571), K. Simrock a modernization in 1864. The earliest translation was that into Dutch; it is undated, but may have appeared as early as 1512 (facsimile reprint, The Hague, 1898). This served as the basis for the first French version: *Ulenspiegel, de sa vie, de ses oeuvres et merveilleuses aduentures par luy faictes, etc.* (1532). Reprint, ed. by P. Jannet (1882). It was followed by upwards of 20 French editions. C. de Coster's *La légende et les aventures d'Ulenspiegel* (Brussels, 1912; Eng. trans. 1918) is a modernization of the legend. The first complete English translation bears the title: *Here beginneth a merye Jest of a man called Howleglas, etc.* printed by Copland in three editions, probably between 1548 and 1560. Reprint by F. Ouvry (1867). There was, however, a still older English edition (1518?), of which the British Museum possesses fragments (reprinted by F. Brie, *Eulenspiegel in England,* 1903). In 1720 appeared *The German Rogue, or the Life and Merry Adventures of Tiel Eulespiegle. Made English from the High-Dutch;* and an English illustrated edition, adapted by K. R. H. Mackenzie in 1880 (repr. in *Broadway Translations*). On Eulenspiegel in England, *see* C. H. Herford, *Studies in the Literary Relations of England and Germany in the Sixteenth Century* (1888), pp. 242 ff., and F. Brie's work referred to.
(J. G. R.)

EULER, LEONHARD (1707–1783), Swiss mathematician, was born at Basel on Apr. 15, 1707. His father, a good mathematician, was a Lutheran pastor. In 1723 he graduated at Basel, where he studied geometry under Jean Bernoulli, at that time one of the first mathematicians in Europe, and became a close friend of his sons, Daniel and Nicolas. He then took up theology and oriental languages, and medicine. In 1727 on the invitation of Catherine I., Euler joined his friends in St. Petersburg, where he became professor of physics in 1730 and three years later of mathematics, in succession to Daniel Bernouilli. The severity of the climate and close application to study affected his health and in 1735 he lost the sight of one eye. In 1741 Euler went to Berlin at the command of Frederick the Great, and during the next 25 years contributed many memoirs to the Prussian Academy. During this period he continued to contribute memoirs to the academy of St. Petersburg, and in 1766 he obtained, though with difficulty, permission to return to Russia. Soon afterwards a cataract formed in his left eye, which left him almost blind; with the help of his sons and of Krafft and Lexell, however, he continued his labours. In the next seven years he sent in 70 memoirs to the Academy, and left in his papers some 200 more. He died of apoplexy on Sept. 18, 1783.

Importance of His Work.—Euler's greatest work was done in pure mathematics, and he must be regarded as one of the founders of the modern science. In his *Introductio in analysin infinitorum* (1748), of which a full analysis is given in Cantor's *Geschichte der Mathematik* (vol. iii.), he provided an introduction to pure analytical mathematics. In the first part he gave the bulk of the matter to be found in treatises on algebra, the theory of equations and trigonometry; the second was devoted to analytical geometry. "In the algebra he paid particular attention to the expansion of various functions in series, and to the summation of given series; and for the first time we find the rule laid down that an infinite series cannot be safely employed unless it is convergent" (W. W. R. Ball, *Short History of Mathematics*). Euler treated trigonometry as a branch of analysis. He introduced (at the same time as Thomas Simpson) the abbreviations now used for the trigonometric functions and made use of the symbols ϵ and π. In the second he made many investigations which were new in his time; he discussed the general equation of the second degree in three dimensions, and classified the surfaces represented by it; he showed that the conic sections were represented by the general equation of the second degree in two dimensions.

His next important works were the *Institutiones calculi differentialis* (1755) and the *Institutiones calculi integralis* (1768–70), which may be said to be the first complete and accurate treatises on the calculus of that time. Beta and Gamma Functions and other original investigations were contained in these works. His *Methodus inveniendi lineas curvas maximi minimive proprietate gaudentes* (1744) is an earlier attempt to elaborate the calculus of variations afterwards perfected by Lagrange. His *Anleitung zur Algebra* (1770; translated and extended by Lagrange 1795) is in two parts, the first treating of determinate and the second of indeterminate algebra.

But though Euler's most important work was done in pure mathematics he was a man of wide culture, interested in many branches of applied mathematics and science. He made important contributions to astronomy, hydrodynamics and optics. His *Theoria motuum lunae* (1772) was based on earlier work of his on the subject. It was completed under terrible difficulties. His house had been burned down and some of his papers destroyed; he was nearly blind, and had to carry all the elaborate computations involved in his head. The complicated work on lunar motion in this treatise formed the basis of the lunar tables subsequently constructed by Mayer. His researches in optics were collected by him in the three vols. of his *Dioptrica* (1771).

A general view of the principal facts of mechanics, optics, acoustics and physical astronomy is provided in his *Lettres a une princesse d'Allemagne sur quelques sujets de physique et de philosophie* (1768–72), written for the use of the princess of Anhalt-Dessau.

A catalogue of Euler's works was drawn up by Fuss, the secretary of the St. Petersburg Academy, which issued some of his papers under the title *Opera Postuma* in 1862. A complete edition of his works was begun in 1926. *See* M. Cantor, *Geschichte der Mathematik* (1906).

EULER NUMBERS or **EULERIAN NUMBERS,** are the coefficients of the expansion:

$$\sec x = \frac{1}{\cos x} = 1 + A_1x^2 + A_2x^4 + A_3x^6 + \cdots.$$

They were so named by the German mathematician Scherk after the man who first discovered their significance in analysis. Although not of such wide application as the Bernouilli numbers, they are interesting on account of their intimate connection with the former, and of their various theoretical properties. They are also used in the summation of certain series. The first nine of these numbers were computed by Euler (*q.v.*). The ninth was found to be erroneous by Rothe, who gave the correct value. H. F. Scherk (1825) computed six more, Glaisher extended the list to 27, and S. A. Joffe computed 23 more, making 50 in all.

Euler used the recurrent formula

$$\frac{A_n}{1} - \frac{A_{n-1}}{2!} + \frac{A_{n-2}}{4!} - \frac{A_{n-3}}{6!} + \cdots = 0,$$

and independent representations in the form of determinants have been given by Glaisher:

$$E_n \quad \begin{vmatrix} \frac{1}{2!} & 1 & \cdots & 0 & 0 \\ \frac{1}{4!} & \frac{1}{2!} & \cdots & 0 & 0 \\ \cdot & \cdot & \cdots & \cdot & \cdot \\ \cdot & \cdot & \cdots & \cdot & \cdot \\ \cdot & \cdot & \cdots & \cdot & \cdot \\ \cdot & \cdot & \cdots & 1 & 0 \\ \cdot & \cdot & \cdots & \frac{1}{2!} & 1 \\ \frac{1}{2n!} & \frac{1}{2n-2!} & \cdots & \frac{1}{4!} & \frac{1}{2!} \end{vmatrix}$$

and by Haussner as follows:

$$E_n = \begin{vmatrix} 1 & 1 & 0 & \cdots & 0 \\ 1 & \binom{4}{2} & 1 & \cdots & 0 \\ 1 & \binom{6}{2} & \binom{6}{4} & \cdots & 0 \\ \cdot & \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdot & \cdots & \cdot \\ 1 & \binom{2m-2}{2} & \binom{2m-2}{4} & \cdots & 1 \\ 1 & \binom{2m}{2} & \binom{2m}{4} & \cdots & \binom{2m}{2m-2} \end{vmatrix}$$

The following formula does not seem to have been given in the memoirs on the subject,

$$E_n = 2n! - B_1(2n-2)! + B_2(2n-4)! + \cdots.$$

where B represents the sum of the products of the squares of the first $n-i+1$ odd numbers taken as products i at a time with repetitions, *e.g.*,

$$\begin{aligned} E_n = 8! &- 6!(1^2+3^2+5^2+7^2) \\ &+ 4!(1^2\cdot 3^2 + 1^2\cdot 5^2 + 3^2\cdot 5^2) \\ &- 2!(1^6 + 1^4\cdot 3^2 + n^2 3^4 + 3^6) + 1. \end{aligned}$$

Binet made the very interesting observation that the nth Eulerian number is equal to the number of permutations that can be formed of $2n$ elements, $a_1, a_2, a_3 \ldots a_{2n}$, such that the index of any element is either larger or smaller than each of the two adjacent indices, *e.g.*, out of the 24 permutations of the four elements, a_1, a_2, a_3, a_4, the following satisfy the above condition:

$$\begin{matrix} a_2 & a_3 & a_1 & a_4 \\ a_3 & a_1 & a_4 & a_2 \\ a_4 & a_2 & a_3 & a_1 \\ a_1 & a_4 & a_2 & a_3 \\ a_2 & a_1 & a_4 & a_3 \end{matrix}$$

totalling 5 distinct permutations, and hence $E_2 = 5$.

Of the theoretical properties of the Eulerian numbers the following are of interest:

1. Every Eulerian number is a positive odd integer.
2. The sum of any two successive Eulerian numbers is divisible by 3.
3. When n is even, $E_n + 1 \equiv 0 \pmod{3}$
4. When n is odd, $E_n - 1 \equiv 0 \pmod{3}$
5. E_n always ends in 1 or 5.

The first 10 Euler numbers are 1, 5, 61, 1385, 50521, 2702765, 199360981, 19391512145, 2404879675441, 370371188237525; and E_{50} is a number of 127 figures.

EUMENES, the name of two rulers of Pergamum.

1. Eumenes I. succeeded his uncle Philetaerus in 263 B.C. The only important event in his reign was his victory near Sardis over Antiochus Soter, which enabled him to secure possession of the districts round his capital. (*See* Pergamum.)

2. Eumenes II., son of Attalus I., was king of Pergamum 197–159 B.C. During the greater part of his reign he was a loyal ally of the Romans. He materially contributed to the defeat of Antiochus of Syria at the battle of Magnesia (190), and as a reward for his services the Thracian Chersonese and all Antiochus's possessions as far as the Taurus were bestowed upon him. Although he supported the Romans in the war against Macedonia, he displayed so little energy and interest that he was suspected of intriguing with the enemy. Nothing, however, came of these negotiations, whatever may have been their real object; and Eumenes, in order to avert suspicion, sent his congratulations to Rome by his brother Attalus after the defeat of Perseus (168). Attalus was received courteously but coldly; and Eumenes in alarm set out to visit Rome in person, but on his arrival at Brundusium was ordered to leave Italy at once. He never regained the good graces of the Romans, who showed especial favour to Attalus on his second visit to Rome, probably with the object of setting him against Eumenes; but the ties of kinship proved too strong. The last years of his reign were disturbed by renewed hostilities against Prusias of Bithynia and the Celts of Galatia, and probably only his death prevented a war with Rome. Eumenes, although physically weak, was a shrewd and vigorous ruler and politician, who raised his little state from insignificance to a powerful monarchy. During his reign Pergamum became a flourishing city, where men of learning were always welcome, among them Crates of Mallus, the founder of the Pergamene school of criticism. The greatest monument of his liberality was the foundation of the library, which was second only to that of Alexandria.

See Livy xxxix. 51, xlii. 11–16; Polybius xxi.–xxxii.; Appian, *Syriaca;* Livy, *Epit.* 46; Cornelius Nepos, *Hannibal,* 10.

EUMENES (*c.* 360–316 B.C.), Macedonian general, was a native of Cardia in the Thracian Chersonesus. He was employed as private secretary by Philip II. of Macedon, and later by Alexander the Great, whom he accompanied into Asia. In the

division of the empire on Alexander's death, Cappadocia and Paphlagonia were assigned to Eumenes; but as they were not yet subdued, Leonnatus and Antigonus were charged by Perdiccas to put him in possession. Antigonus, however, disregarded the order, and Leonnatus in vain attempted to induce Eumenes to accompany him to Europe. Eumenes joined Perdiccas, who installed him in Cappadocia. When Craterus and Antipater, having reduced Greece, determined to pass into Asia and overthrow Perdiccas, their first blow was at Cappadocia. Craterus and Neoptolemus, satrap of Armenia, were defeated by Eumenes (321); Neoptolemus was killed, and Craterus died of his wounds. After the murder of Perdiccas in Egypt by his own soldiers, the Macedonian generals condemned Eumenes to death, and charged Antipater and Antigonus with the execution of the order. Eumenes fled to Nora, on the confines of Cappadocia and Lycaonia, where he defended himself for more than a year. Antipater left the regency to his friend Polyperchon over the head of his son Cassander, who entered into an alliance with Antigonus and Ptolemy against Polyperchon, supported by Eumenes, who had escaped from Nora. In 318 Antigonus marched against him, and Eumenes withdrew east to join the satraps of the provinces beyond the Tigris. After two indecisive battles in Iran, Eumenes was betrayed by his own soldiers to Antigonus and put to death. He was an able soldier, who did his utmost to maintain the unity of Alexander's empire in Asia; but his efforts were frustrated by the generals and satraps, who hated and despised the "secretary" and "foreigner."

See Plutarch, *Eumenes;* Cornelius Nepos, *Eumenes;* Diod. Sic. xviii., xix.; Arrian, *Anabasis,* vii.; Quintus Curtius x. 4. 10; Justin xiii. 8; also MACEDONIAN EMPIRE.

EUMENIDES, ancient goddesses, also called *Semnai* ("reverend ones") worshipped at the foot of the Areiopagus at Athens, at Colonus, and in places outside Attica. Their cult closely resembled that of Gē (earth), and they were probably earth-spirits, largely concerned with fertility, but having also certain moral and social functions. By and after Aeschylus (q.v.) they were generally identified, although wrongly, with the Erinyes (q.v.). (From Gr. εὐμενής, kindly.)

See L. Farnell, *Cults of the Greek States,* v., p. 440.

EUMENIUS (*c.* A.D. 260–311), one of the Roman panegyrists, was born at Augustodunum (*Autun*) in Gallia Lugdunensis. He was of Greek descent. He became *magister memoriae* (private secretary) to Constantius Chlorus. In 296 Chlorus determined to restore the famous schools (*scholae Maenianae*) of Autun, and appointed Eumenius to the management of them. There is no doubt that Eumenius was a heathen, not even a nominal follower of Christianity. Nothing is known of his later years; but he must have lived at least till 311, if the *Gratiarum Actio* to Constantine is by him. Of the 12 discourses included in the collection of *Panegyrici Latini* (ed. E. Bährens, 1874), the following are probably by Eumenius: (1) *Pro restaurandis* (or *instaurandis*) *scholis,* delivered (297) in the forum at Autun before the governor of the province. Its chief object is to set forth the steps necessary to restore the schools to their former state of efficiency, and the author lays stress upon the fact that he intends to assist the good work out of his own pocket. (2) An address (297) to the Caesar Constantius Chlorus, congratulating him on his victories over Allectus and Carausius in Britain. (3) A panegyric on Constantine (310). (4) An address of thanks (311) from the inhabitants of Autun to Constantine for remission of taxes and other benefits. (5) A festal address (307) on the marriage of Constantine and Fausta. All these speeches, with the exception of (1), were delivered at Augusta Trevirorum (Trèves), whose birthday is celebrated in (3). Eumenius was far the best of the orators of his time, and in his restraint and moderation superior to most of the writers of imperial panegyrics.

There are treatises on Eumenius by B. Kilian (Würzburg, 1869), S. Brandt (Freiburg-im-Breisgau, 1882), and H. Sachs (Halle, 1885); *see* also Gaston Boissier, "Les Rhéteurs gaulois du IVe siècle," in *Journal des savants* (1884).

EUMOLPUS. The priestly clan of the Eumolpidae at Eleusis (*see* MYSTERY) claimed descent from a certain Eumolpus ("good or strong singer;" *i.e.,* priest who can chant his litanies clearly and well), an obvious personification of their hereditary functions. As might be expected in the case of so shadowy a figure, his legend fluctuates greatly, so much so that three Eumolpi have been assumed, quite unnecessarily, however. (1) Being a "sweet singer," he is naturally connected with Thrace, the country of Orpheus (*q.v.*). He is son of Poseidon and Chione ("Snow-girl"), daughter of Boreas; after sundry adventures he becomes king in Thrace, is invited to help the Eleusinians in their war with Erechtheus (*q.v.*), and is killed in the war. (2) As one of the originators of the Eleusinian mysteries, he is an Eleusinian, a son of Earth, father of *Kērux,* the mythical ancestor of the *Kērukes* (*see* MYSTERY), taught the mysteries by Demeter herself. (3) Since Orpheus and all his following were closely connected with mysteries of all sorts, Eumolpus is son, father or pupil of Musaeus. Further confusion is introduced by his being sometimes called son, not father, of *Kērux,* possibly a reflection of some old dispute over precedence between the two clans. As a priest, he purifies Heracles from the blood of the Centaurs, and also initiates him; as connected with the Orphic circle, he is a culture-hero, maker of various advances in the useful and fine arts. His tomb was shown both at Eleusis and in Athens.

See Engelmann in Roscher's *Lexikon s.v.* (authorities).

EUNAPIUS, Greek sophist and historian, was born at Sardis, A.D. 347. At Athens he became a favourite pupil of Proaeresius the rhetorician, and later taught rhetoric. Initiated into the Eleusinian mysteries, he was admitted into the college of the Eumolpidae and became hierophant. He was the author of *Lives of the Sophists* (Βίοι φιλοσόφων καὶ σοφιστῶν), still extant, and a continuation of the history of Dexippus (*q.v.*). Of the latter only excerpts remain, but the facts are largely incorporated in the work of Zosimus. It embraced the history of events from A.D. 270–404. The *Lives of the Sophists* is valuable as the only source for the history of contemporary neo-Platonism. Both works are marked by hostility to Christianity.

The *Lives* was edited by J. F. Boissonade (1822), with notes by D. Wyttenbach and by W. C. Wright with an Eng. trs. in Loeb series (1922); history fragments in C. W. Müller, *Fragmenta Hist. Graecorum,* iv.; *see* also Uberweg, *Grund. der gesch. der phil.* pt. I. (1926).

EUNOMIUS (d. *c.* 393), a leader of the extreme or "anomoian" Arians, sometimes called Eunomians, was born at Dacora, Cappadocia, early in the 4th century. He studied at Alexandria and was ordained deacon at Antioch. Through Eudoxius he was appointed bishop of Cyzicus in 360, but Eudoxius was compelled, by command of the emperor, Constantius II., to depose him from the bishopric a year later because of his extreme Arian views. Eunomius went to Constantinople and then to Chalcedon, whence in 367 he was banished to Mauretania for harbouring the rebel Procopius. He was recalled, however, before he reached his destination. In 383 the emperor Theodosius banished him to Halmyris in Moesia. He afterwards resided at Chalcedon, at Caesarea in Cappadocia, from which he was expelled by the inhabitants for writing against their bishop Basil, and lastly at Dacora. The influence of his writings was so much dreaded by the orthodox, that more than one imperial edict was issued for their destruction (*Cod. Theod.* xvi. 34). Consequently his commentary on the epistle to the Romans, mentioned by the historian Socrates, and his epistles, mentioned by Philostorgius and Photius, are lost. His first apologetical work (Ἀπολογητικός) written *c.* 360 or 365, has been recovered from the celebrated refutation of it by Basil, and is in J. A. Fabricius, *Bibl. Gr.* viii. Of a second apology written before 379 (Ὑπὲρ ἀπολογίας ἀπολογία), there are only quotations in a refutation by Gregory of Nyssa. The exposition of faith (Ἔκθεσις τῆς πίστεως), demanded by Theodosius, has been edited by Valesius in his notes to Socrates, and by Ch. H. G. Rettberg in his *Marcelliana.*

The teaching of the Anomoians, led by Aetius and Eunomius, starting from the conception of God as ὁ ἀγέννητος, argued that between the ἀγέννητος and γέννητος there could be no *essential,* but at best only a *moral,* resemblance. According to Socrates (v. 24), Eunomius, instead of baptizing in the name of the Trinity, baptized in the name of the Creator and into the death of Christ. The Eunomian heresy was formerly condemned by the council

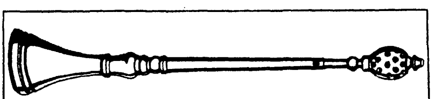
of Constantinople in 381.

See C. R. W. Klose, *Geschichte und Lehre des Eumonius* (Kiel, 1833); F. Loofs in Hauck-Herzog, *Realencyk.*; Whiston's *Eunomianismus redivivus* contains an English translation of the first apology. *See* also ARIUS.

EUNUCH, a castrated human male. From remote antiquity among the Orientals, as also at a later period in Greece, eunuchs were employed to take charge of the women, or generally as chamberlains. Their confidential position in the harems of princes frequently enabled them to exercise an important influence over their royal masters, and even to raise themselves to stations of great trust and power (*see* HAREM). Hence the term eunuch came to be applied in Egypt to any court officer, whether a *castratus* or not. The common idea that eunuchs are necessarily deficient in courage and in intellectual vigour is amply refuted by history. Herodotus states that in Persia they were especially prized for their fidelity; and they were frequently promoted to the highest offices. The capacity of eunuchs for public affairs is strikingly illustrated by the histories of Persia, India and China; and considerable power was exercised by the eunuchs under the later Roman emperors. The hideous trade of castrating boys to be sold as eunuchs for Muslim harems has continued to modern times, the principal district whence they are taken being north-central Africa (Bagirmi, etc.). The Italian practice of castrating boys in order to train them as adult soprano singers ended with the accession of Pope Leo XIII. Voluntary eunuchs who emasculated themselves, or caused the operation to be performed on them, for the avoidance of sexual sin or temptation, appeared in early Christian ages, its votaries acting on the texts Matt. xix. 12, v. 28–30. Origen's case is the most celebrated example, and by the 3rd century there had arisen a sect of eunuchs, of whom Augustine says (*De haeres.* c. 37), "*Valesii et seipsos castrant et hospites suos, hoc modo existimantes Deo se debere servire.*" (The Valesii castrate themselves and their guests, thinking thereby to serve God.) A sect of the kind exists in Russia, whose practice is expressed in their name of Skopzi.

EUNUCH FLUTE or ONION FLUTE, a wind instrument in use during the 16th and 17th centuries, producing music akin to the comb-music of the nursery, and still manufactured as a toy (*mirliton*). It consists of a wooden tube widening out slightly to form a bell and closed at its upper end by means of a very fine membrane. The mouthpiece, a simple round hole, is pierced a couple of inches below the membrane; into this hole the performer sings, his voice setting up vibrations in the membrane, which thus intensifies the sound and changes its timbre to a bleating quality.

EUONYMUS, in botany, a genus of deciduous or evergreen shrubs or small trees of the staff-tree family (*Celastraceae*). It comprises upwards of 100 species, widely distributed in the north temperate zone, and represented in Great Britain by *E. europaeus*, the spindle-tree. It is a shrub or small tree growing in copses or hedges, with a grey smooth bark, four-angled green twigs, opposite



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

EUNUCH FLUTE, A 16TH CENTURY INSTRUMENT, THE MOUTHPIECE OF WHICH WAS CLOSED BY A PIECE OF PARCHMENT OR SKIN, GIVING IT A CURIOUS BLEATING TIMBRE

leaves and loose clusters of small greenish-white flowers. The ripe fruit is a pale crimson colour and splits into four lobes exposing the bright orange-coloured seed. Besides the spindle-tree, which has become naturalized in the eastern United States, the genus is represented in North America by *E. americanus* (strawberry bush), *E. obovatus* (creeping strawberry bush), *E. atropurpureus* (wahoo), and *E. occidentalis* (western wahoo). Numerous species are in cultivation, among which are *E. japonicus*, a handsome evergreen often with variegated leaves, and *E. repens*, a hardy climber for walls, especially the var. *vegetus*, which bears profuse persistent fruits. The flowering was said to foretell plague.

EUPALINUS, of Megara, a Greek architect, who constructed for the tyrant Polycrates of Samos a tunnel under a hill to bring water to the city. This aqueduct still exists, and is one of the most remarkable constructions in Greece. (*See* AQUEDUCTS.)

EUPATORIA, a seaport on the west coast of the Crimean A.S.S.R., 20 m. north-west of Simferopol, on a sandy promontory on the north of Kalamita Bay, in lat. 45° 15′ N., long. 33° 23′ E. The town is also known as Kozlov. Pop. (1926) 23,341. This number includes many Jews, the Karaite sect having their principal synagogue here. Of its numerous ecclesiastical buildings three are of interest—the synagogue of the Karaite Jews; one of the mosques, which has fourteen cupolas and was built (1552) after the plan of St. Sophia in Constantinople; and the Greek Catholic cathedral (1898). The roadstead has a sandy bottom, and is exposed to violent storms from the north-east. It is connected by a branch line with the main north to south railway. The trade is principally in cereals, skins, cow-hair, felt, tallow and salt. Its industries include the making of machines and chemical products, and the preparation of salt and of dried fish. Eupatoria has some repute as a sea-bathing resort.

According to some authorities it was near this spot that a military post, *Eupatorium*, was established in the 1st century A.D. by Diophantus, the general of Mithridates the Great, king of Pontus. Towards the end of the 15th century the Turks built the fortress of Gezleveh on the present site, and it became the capital of a khanate. It was occupied by the Russians under Marshal Münnich in 1736, and in 1771 by Prince Dolgorukov. Its annexation to Russia took place in 1783. In 1854 the Anglo-French troops were landed in the neighbourhood of Eupatoria, and in February 1855 the town was occupied by the Turkish forces.

EUPATORIUM, a numerous genus of plants of the family Compositae, comprising more than 500 species, nearly all American and found chiefly in tropical South America, the West Indies and Mexico. They are mostly perennial herbs, a few are annuals, and many tropical species are shrubby or tree-like. The leaves are usually opposite and the flowers are borne in rayless heads disposed usually in flat-topped clusters. Of the few Old World species, one, *E. cannabinum*, the hemp-agrimony, occurs in Great Britain. Upwards of 60 species are found in the United States and Canada, widely distributed but mostly in the eastern, southern and south-western States, very few occurring on the Pacific coast. Representative North American species are *E. perfoliatum*, boneset (*q.v.*); *E. purpureum*, Joe-Pye weed; *E. urticaefolium*, white snake-root; and *E. coelestinum*, mist-flower. Various tropical forms are in greenhouse cultivation and several hardy species are grown as border plants.

EUPATRIDAE, the ancient nobility of Attica (the Greek word means "sons of noble fathers"). Tradition ascribes to Theseus, whom it regards as the author of the *synoecism* (συνοικισμός), the union of Attica round Athens as a political centre, the division of the Attic population into three classes, *Eupatridai*, *Geōmoroi*, and *Dēmiourgoi*. The Eupatridae are described as the autochthonous population (*see* AUTOCHTHONES), the dwellers in the city, the descendants of the royal stock. After the time of the *synoecism* the nobles were obliged to reside in Athens, now the seat of government; and at the beginning of Athenian history the noble clans form a class which has the monopoly of political privilege. It is possible that in very early times the Eupatridae were the only full citizens of Athens.

The exact relation of the Eupatridae to the other two classes has been a matter of dispute. It seems probable that the Eupatridae were the governing class, the recognized nobility, the *Geōmoroi* the country inhabitants of all ranks, and the *Dēmiourgoi* the commercial and artisan population. It seems certain from the little known of the early constitutional history of Athens that the Eupatridae represented the only nobility that had any political recognition in early times. The political history of the Eupatridae is that of a gradual curtailment of privilege. They were at the height of their power in the period during the limitation of the monarchy. They alone held the two offices, those of polemarch and archon,

which were instituted during the 8th century B.C. to restrict the powers of the kings. In 712 B.C. the office of king (βασιλεύς) was itself thrown open to all Eupatrids (*see* ARCHON). They thus had the entire control of the administration and were the sole dispensers of justice in the State. At this latter privilege, which perhaps formed the strongest bulwark of the authority of the Eupatridae, a severe blow was struck (*c.* 621 B.C.) by the publication of a criminal code by Draco (*q.v.*), which was followed by the more detailed and permanent code of Solon (*c.* 594 B.C.), who further threw open the highest offices to any citizen possessed of a certain amount of landed property (*see* SOLON), thus putting the claims of the Eupatridae to political influence on a level with those of the wealthier citizens of all classes. By the middle of the 6th century the political influence of birth was at an end.

The name Eupatridae survived in historical times, but the Eupatridae were then excluded from the cult of the *Semnai* at Athens, and also held the hereditary office of "expounder of the law" (ἐξηγητής) in connection with purification from the guilt of murder. Isocrates says of Alcibiades that his grandfather was a Eupatrid and his grandmother an Alcmaeonid, which suggests that in the 5th century the Eupatrids were a single clan, like the Alcmaeonids, and that the name had acquired a new signification. This "Eupatrid" clan seems to have traced its origin to Orestes, "the benefactor of his father." *See* also AREOPAGUS, ARCHON.

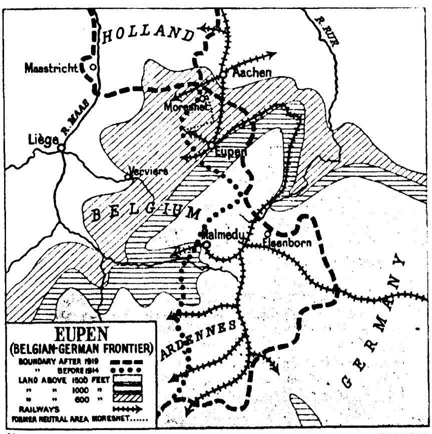
EUPEN AND MALMÉDY, two districts acquired by Belgium from Rhenish Prussia in 1919, with the small district of Moresnet. The latter, by an oversight in the Treaty of Vienna in 1815 was not assigned to either Belgium or Prussia, and part of it



MAP SHOWING BELGIAN-GERMAN FRONTIER BEFORE 1914 AND AFTER 1919

therefore remained neutral territory between the two countries. It comprised little over 3,000 inhabitants (census of 1910).

Prior to 1914 the boundary of Germany overlooked the valley of the right bank tributaries of the Meuse. The cession of Malmédy took the frontier eastward to the watershed between the feeders of the Meuse and those of the Moselle and Rhine, while the cession of Eupen removed the frontier from the vicinity of Verviers to that of Aachen. These changes transferred to Belgium important sections of the German railway system which had been developed near this frontier.

Eupen and Malmédy contain some 60,000 persons of whom less than one-sixth are Walloon and French-speaking, and five-sixths German. It was contended at the Peace Conference that these inhabitants had been systematically Prussianized since 1815. It seems true that the majority spoke French before that date, and were, in origin, Walloons. The conference therefore declined to sanction a plebiscite, but the inhabitants were permitted to express their opinions in registers for six months after the ratification of the treaty, Jan. 10, 1920. The League of Nations, to which the case was referred, ultimately assigned the areas to Belgium. By a decree of March 6, 1925, Eupen and Malmédy were joined to the province of Liége.

The Allied Powers (reply to the German observations on the draft treaty, June 16, 1919) based the fate of these areas on grounds other than those of self-determination. Eupen and Malmédy had been made a basis for German militarism, and had a close economic connection with Belgium. Moresnet, which had valuable woods, was assigned to Belgium "in partial compensation for the destruction of Belgian forests."

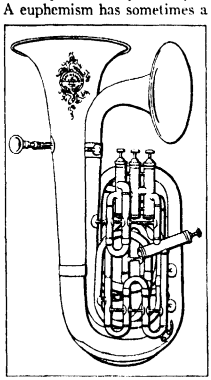
EUPHEMISM, a figure of speech in which an unpleasant or coarse phrase is replaced by a softer or less offensive expression. A euphemism has sometimes a metaphorical sense, as in the substitution of the word "sleep" for "death."



BY COURTESY OF CARL FISCHER
THE EUPHONIUM, THE HIGHEST PITCHED MEMBER OF THE FAMILY OF BRASS WIND-VALVE INSTRUMENTS KNOWN AS TUBAS

EUPHONIUM, a modern brass wind instrument, known in military bands as euphonium and in the orchestra as tuba. The euphonium consists of a brass tube with a conical bore of wide calibre ending in a wide-mouthed bell; it is played by means of a cup-shaped mouthpiece. The sound is produced as in the bombardon, which is the bass of the euphonium, by the varied tension of the lips across the mouthpiece, whereby the natural open notes or harmonics are obtained. The intervening notes of the chromatic scale are obtained by means of valves or pistons. The quality of tone is rich and full, blending well with that of the trombone. (*See* BOMBARDON.)

EUPHORBIA, in botany, a large genus of plants from which the family Euphorbiaceae takes its name. It includes about 750 species and is of almost world-wide distribution. It is represented in Great Britain and North America by the spurges—small, generally smooth, herbaceous plants with simple leaves and inconspicuous flowers arranged in small cup-like heads (*cyathia*). The cyathium is characteristic of the genus, and consists of a number of male flowers, each reduced to a single stamen, surrounding a central female flower which consists only of a stalked pistil; the group of flowers is enveloped in a cup formed by the union of four or five bracts, the upper part of which bears thick, conspicuous, gland-like structures, which in exotic species are often brilliantly coloured, giving the cyathium the appearance of a single flower (*e.g.*, the so-called Poinsettias). Another characteristic is the presence of a milky juice, or latex, in the tissues of the plant. In one section of the genus the plants resemble cacti, having a thick succulent stem and branches with the leaves very small or reduced to a small wart-like excrescence, with which is generally associated a tuft of spines (a reduced shoot). These occur in the warmer parts of the world and are essentially dry country or desert vegetation.

EUPHORBIACEAE, in botany, a large family of flowering plants, containing 220 genera with about 4,000 species, chiefly tropical, but spreading over the whole earth with the exception of the arctic and cold alpine zones. They are represented in Great

Britain and North America chiefly by the spurges (*Euphorbia*, *q.v.*) (fig. 1), which are herbaceous, but the greater number are woody, often trees. The large genus *Euphorbia* shows great variety in habit; many species, like the English and most North American spurges, are annual herbs, others form bushes, while in the desert regions of tropical Africa and the Canary Islands species occur resembling cacti, having thick fleshy stems and leaves reduced to spines. Another large genus, *Phyllanthus*, contains small annual herbs as well as trees, while in some species the leaves are reduced to scales, and the branches are flattened, forming phylloclades. The leaves also show great variety in form and arrangement, being simple and entire as in the English spurges, or deeply cut as seen in *Ricinus* (castor-oil) and *Manihot* or palmately compound (*Hevea*). The majority contain a milky juice or latex in their tissues which exudes on cutting or bruising. In *Hevea*, *Manihot* and others the latex yields caoutchouc. The flowers are unisexual; male and female flowers are born on the same, as occurs in the spurges, or on different plants, as in dog's mercury. Their arrangement shows considerable variation, but the flowers are generally grouped in crowded definite partial inflorescences, which are themselves arranged in spikes or stand in the axils of the upper leaves. These partial inflorescences are generally unisexual, the male often containing numerous flowers while the female flowers are solitary. The partial inflorescence (*cyathium*) of *Euphorbia* (fig. 1) resembles superficially a hermaphrodite flower. It contains a central terminal flower, consisting of a naked pistil; below this are borne four or five bracts which unite to form a cup-shaped involucre resembling a calyx; each of these bracts subtends a small cyme of male flowers each consisting only of one stamen. Between the segments of the cup are large oval or crescent-shaped glands, often brightly coloured, forming petal-like structures.

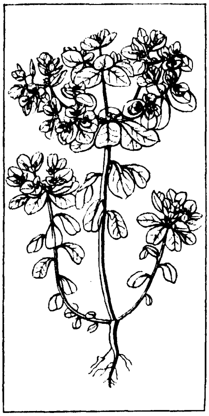


FIG. 1.—A SPURGE, EUPHORBIA HELIOSCOPIA, SHOWING GENERAL HABIT OF GROWTH
The cells of the plant contain latex, a milky-looking fluid

The form of the flower shows great variety. The most complete type occurs in *Wielandia*, a shrub from the Seychelles Islands, in which the flowers have their parts in fives, a calyx and corolla being succeeded in the male flower by 5 stamens, in the female by 5 carpels. Generally, however, only 3 carpels are present, as in *Euphorbia; Mercurialis* has minute apetalous flowers with 3 sepals, followed in the male by 8 to 20 stamens, in the female by a bicarpellary pistil. In many genera the corolla is absent. The most reduced type of flower is that described under EUPHORBIA. The stamens are sometimes more or less united (monadelphous), and in castor-oil (*Ricinus*) are much branched. The ovary generally contains three chambers, and bears three simple or more often bipartite styles; each chamber contains one or two pendulous ovules, which generally bear a cap-like outgrowth or *caruncle*, which persists in the seed.

As the stamens and pistil are borne by different flowers, cross-pollination is necessary. In *Mercurialis* and others with inconspicuous flowers pollination is effected by the wind, but in many cases insects are attracted to the flower by the highly-coloured bracts, as in many *Euphorbias* and *Dalechampia*, or by the coloured calyx as in *Manihot;* the presence of honey is also frequently an attraction, as in the honey-glands on the bracts of the cyathium of *Euphorbia*. The fruit is generally a capsule which splits into three divisions (*cocci*), separating from the central column, and splitting lengthwise into two halves. In the manchineel (*Hippomane Mancinella*) of Central America the fruit is a drupe like a plum, and in some genera berries occur. In the sandbox tree (*Hura crepitans*) of tropical America the ovary consists of numerous carpels, and forms when mature a capsule which splits with explosive violence into a number of woody cocci. The seeds contain abundant endosperm and a large embryo.

Several members of the family are of economic importance. *Manihot utilissima*, manioc or cassava (*q.v.*), is one of the most important tropical food-plants, its thick tuberous root being rich in starch; it is the source of Brazilian arrowroot. Caoutchouc or india-rubber is obtained from species of *Hevea, Mabea, Manihot* and *Sapium*. Castor-oil (*q.v.*) is obtained from the seeds of *Ricinus communis*. The seeds of *Aleurites triloba* and *Sapium sebiferum* also yield oil. Resin is obtained from species of *Croton* and *Euphorbia*. Many of the species are poisonous; *e.g.*, the South African *Toxicodendron*, one of the most poisonous plants known. Many, such as *Euphorbia, Mercurialis, Croton, Jatropha, Tragia*, have been, or still are, used as medicines. Species of *Codiaeum* (*q.v.*), *Croton, Euphorbia, Phyllanthus, Jatropha* and others are used as ornamental plants in gardens.

The box (*Buxus*) and a few allied genera, formerly included in Euphorbiaceae, are now generally regarded as forming a distinct family, Buxaceae, differing from Euphorbiaceae in the position of the ovule in the ovary-chamber and in the manner of splitting of the fruit.

EUPHORBIUM, an acrid dull-yellow or brown resin, consisting of the concreted milky juice of several species of *Euphorbia*, cactus-like perennial plants indigenous to Morocco. It dissolves in alcohol, ether, and turpentine; in water it is only slightly soluble. It consists of two or more resins and a substance euphorbone, $C_{20}H_{36}O$ or $C_{15}H_{24}O$. In former times euphorbium was valued in medicine for its drastic purgative and emetic properties.

EUPHORBUS, son of Panthus, a Trojan hero, slain by Menelaus (*Iliad*, xvii. 1–60). Pythagoras, in support of his doctrine of the transmigration of souls, declared that he had once been this Euphorbus. (Horace, *Odes*, i. 28. ii.; Diog. Laert. viii. i.)

EUPHORION, Greek poet and grammarian, born at Chalcis in Euboea about 275 B.C. He spent much of his life in Athens, where he amassed great wealth. About 221 he was invited by Antiochus the Great to the court of Syria. He assisted in the formation of the royal library at Antioch, of which he held the post of librarian till his death. He wrote mythological epics, amatory elegies, epigrams and a satirical poem (Ἀραί "curses"). Prose works on antiquities and history are also attributed to him. His elegies were esteemed by the Romans; they were imitated or translated by Cornelius Gallus and also by the emperor Tiberius.

Fragments in Meineke, "De Euphorionis Chalcidensis vita et scriptis," in his *Analecta Alexandrina* (1843); for another fragment of about 30 lines see *Berliner Klassikertexte*, v. i. (1907).

EUPHRANOR, of Corinth (dated by Pliny in 364 B.C.), a Greek artist who excelled both as a sculptor and as a painter. In Pliny we have lists of his works; among the paintings, a cavalry battle, a Theseus, and the feigned madness of Odysseus; among the statues, Paris, Leto with her children Apollo and Artemis, Philip and Alexander in chariots. Unfortunately we are unable among existing statues to identify any as copies from works of Euphranor (for attempts to do so *cf.* Six in *Jahrbuch*, 1909, 7 ff., and Furtwängler, *Masterpieces* pp. 348 ff.). He appears to have resembled Lysippus, in his preference for bodily forms slighter than those usual in earlier art, and in his love of heroic subjects. He wrote books on proportion and colour.

EUPHRATES (Shatt al Fara, Frat su) the largest river of western Asia, and the western of the two streams which flow through Mesopotamia into the Persian gulf. It may be divided into three divisions, an upper, middle and lower, the first extending as far as Samsat, the second to Hit, and the third to its junction with the Tigris at Kurna, the united stream thus formed being known as the Shatt al Arab (*q.v.*). Pliny writing in the first century A.D. says that the Euphrates originally had its own mouth (*see* MESOPOTAMIA: *Geology*) and within historical times the lower course of the river has changed considerably. The shore line at the end of glacial times appears to have been near Hit. Below this point the river has tended to move westwards, the old channel

in Sumerian times corresponding more or less to modern Shatt al Nil, while to-day the river shows a tendency, so far more or less overcome, to desert its bed which passes the ruins of Babylon, the Hilla branch, and to follow a yet more westerly channel, the Hindiya branch. The importance of these changes to human history have been very considerable (*see* MESOPOTAMIA: *Ancient Geography*). Owing to the fact that the Euphrates floods in spring, just before the burning heat of the summer, it has been necessary to use it for perennial irrigation. The tendency has been to dig canals at low water; during flood the river has tended therefore to carry silt into the irrigation canals and often to desert its bed with disastrous results. Most of the changes in the stream appear to have been the result of man's action, followed by the natural flooding of the river. The history of the river has gradually resulted in its becoming less useful to man as it moved westwards from the Tigris, and made the emptying of the canals supplied by the Euphrates (but running into the Tigris) more and more difficult. Measures of conservation have been undertaken since Sumerian times, but these measures have been continually frustrated by the action of riparian owners, who disregarding the efforts alike of Rim-sin and Alexander, have persisted in raising the water level by dikes and have neglected to keep the minor channels deep.

In addition to this westward movement the river since glacial times has been continually pushing its delta southward, combining with other streams, to form first lakes, then marshes and finally dry land (for further details, *see* MESOPOTAMIA: *Geography*).

The Upper Division.—The upper Euphrates consists of two arms, the Kara su (Western Euphrates), the more northerly branch, and the Murad su (Eastern Euphrates). These two streams flow from the Armenian plateau along shallow valleys uniting west of Arabkir, and after cutting through the Taurus flow down from the foothills into Mesopotamia. The *Kara su,* considered by the Arab geographers as the main stream, and formerly the eastern boundary of the Roman Empire rises in Dumlu Dagh, north-north-west of Erzerum at an altitude of 8,625 ft., and flows south-east to the plain of Erzerum. From this point it flows west-south-west through a narrow valley to Erzingan, being joined by the Ovajik su on the right bank, the Tuzla su on the left, and the Merjan and the Chanduklu on the right. From this point the river flows south-west through a rocky gorge to Kemakh, at which point it is crossed by a bridge and receives the Kumur su. Between Avshin and Pingan, where it is crossed by a bridge, it flows through a canyon about 1,000 ft. deep. Below it is joined on the right bank by the Chalta Irmak. From this point its gorge, until it joins the Murad su, is famous for its wild scenery and precipitous walls. The Kara su is a rapid stream of considerable size and is navigable downstream for rafts below Erzingan. It communicates by a low and easy pass with the Aras (Araxes) valley and from this point westwards a road runs which has formed both an ancient trade route and a ready means of access for invading barbarians from the east.

The *Murad su,* although longer and of greater size, has never formed a highway of communication, owing partly to the smallness of its valley below Mush, and has acquired less historical fame. It rises at a height of 11,500 ft. on the northern side of Ala Dagh, south west of Diadin. From this point it flows west to the Arishkerd plain, where it is joined by the Sharian su. Through the trough formed by the two valleys passes the trade route from Erzerum to northern Persia. The river then runs through the mountains to the south and has two tributaries, the Patnotz on the left bank and the Khinis su on the right. It flows in a double bend in a general southwesterly direction through the plain of Bulanik to the plain of Mush, where it is joined by another river usually known as Kara su (the name means black water and is applied to several rivers) which rises near Lake Van. Below Mush its valley is much contracted; it runs west-south-west through a rocky gorge into which flows the Gunig su (on its right bank) as far as Palu. From this point the valley is more open. About ten miles east-north-east of Kharput the Peri su, which drains the Dersim, a mountainous region between the two main branches of the Euphrates, and is the most important tributary of the Murad su, falls into it.

The length of the Murad su to its junction with the Kara su is 415 miles, the length of the latter being 275 miles. From this point the Euphrates flows in a southwesterly direction past the lead mines at Keban Maden, where it is crossed by a ferry, 120 yd. across, on the road from Kharput to Sivas. It then runs in a great bend round the Musher Dagh, and is joined by the Kuru Chai, down whose valley the road from Malatia to Sivas runs, and the Tokhma su. Shortly below the ferry it enters a deep gorge and runs through the Taurus range in a rapid fall, the course of the river being much interrupted by rapids. It runs south east, close to the source of the western Tigris, and then turns at right angles and flows south-west leaving the mountains a few miles above Samsat (Samosata), the distance from the junction of the main two rivers to the latter town being 115 miles.

The Middle Division.—The middle division of the river, from the mountains above Samosata to the old shore line at Hit, is a little over 700 miles. The valley bed here is a few miles wide and covered with a bed of alluvium. The country is treeless and open and though sparsely populated it is to a certain extent irrigated, within the actual zone of the valley itself. Two methods of irrigation are used, the more modern is the draw well, where a skin is lowered into the water and raised by oxen. The more ancient method is however of greater importance because of the obstacles which it sets to navigation. The method used is the construction of great wheels, like those used on some of the rivers of China. These wheels carry earthen vessels which pick up a small proportion of the water and discharge into aqueducts carried on arches, which form a serious obstacle in the path of the stream. Much of the valley is to-day desolate and the desert approaches to the rocky edge of the valley sides. In ancient times the valley appears to have been inhabited as far as the mouth of the Khabur, the principal towns being on the left bank. To-day however from Birijik southwards the river is very desolate and little known, the principal towns, which are Samsat, Birijik, Kalaat en Nidjin, Meskene, Rakka, Madan, Dier ez Zor, Ana and Hit, being all on the right bank except Birijik and Rakka, the latter however is at the confluence of a tributary stream. A caravan road runs along this bank, and there are posts along the road, but the whole scenery is one extremely desolate. This feeling of desolation is enhanced by the geological strata through which the river has cut its valley. They consist of marls and gypsum, overlaid with sandstone and topped with breccia or conglomerate. In places the erosion has produced curious flat-topped hills, sometimes rising a hundred or more feet above the river. Above Deir ez Zor the river has cut through a dike of basalt, along the south side of the extension of which the road runs west from Deir to Tadmor.

This now desolate stretch of the river was of great importance historically. It separated for long the Assyrian and Hittite empires, and was the dividing line between the western and eastern satrapies of the Persian Empire, while at various times it formed the boundary of the Roman Empire. During the Mongol tenure of Mesopotamia it formed a fortified frontier against the Mongols. The ancient ruins along this frontier are numerous and important. Samsat is built on the site of Samosata, the capital of the Seleucid kings of Commagene; it is situated at an old crossing point of the river, and the old road from Susa to Sardis probably passed through it. A little lower down the river, at the point where the Sanjeh (Σίγγας) joins the main stream, stands the Rum-Kaleh, an ancient castle on a high rock defending another ancient crossing; 25 m. south of this point is Birijik (ancient Birtha, the Apamea Zeugma), the point at which the main road from east to west crosses the river, as it has done for many centuries. The point is only just over a hundred miles from the Mediterranean at an altitude of 628 feet. From this important caravan centre the river runs sluggishly southwards past Jerablus (Carchemish), which lies close to the junction of the Sajur (Sagara), to Meskene, close to which are the ruins of Barbalissus, now a short distance from the river, but formerly a river port for the overland trade with Aleppo. At this point the river road turns westwards and crosses the desert to Aleppo. Six miles below this again is another important crossing point Thapsacus (modern Kalaat Dibse). This was

probably the most important of all the passages of the river in this region. It formed the point for the starting of caravans in ancient times. Cyrus here crossed the river and it was this passage which was used by Alexander. At this point the river takes a sharp bend to the east. From here onwards there are a succession of ancient towns. A few miles below Thapsacus there lies on the west bank the Kalaat Jaber (Dausera), while on the opposite bank is the more ancient Siffin (Roman Sephe). Below this again is another Roman frontier post, Sura, on the west bank, and 20 m. south of this, but away from the river, the ruins of Reseph. Below Sura (but on the other side of the river) are the ruins of Heraklea (Haragla). At the point where the Belikh, an important tributary joins the Euphrates, is the site of Nicephorum (modern Rakka) called Callinicus in Seleucid and Roman times and at one time the capital of Harun al Raschid. The Belikh (Bilechas) is a river of some importance in antiquity, on whose banks are Urfa (Edessa *q.v.*) and Harran (Carrhae). Below Rakka, at the point already mentioned where the river cuts through a basaltic dike, are two great ruins: on the left bank Zelebiya, on the right Halebiya (Zenobia), which are situated about 26 m. above Deir-ez Zor. Below Deir the river opens out into a large plain and runs through two channels. This point has also been a ford of considerable importance and today is the meeting point of the western road, which goes by Palmyra, and the eastern road to Mosul, in addition to the up and down river road. The site is one of great antiquity and there are numerous ancient mounds. Below Deir the Khabur joins the left bank of the Euphrates, flowing from the foothills to the north. This stream, which has one important tributary the Jaghijagh (Mygdonius) was the frontier of the Roman empire from the time of Diocletian. At this point are the ruins of the Roman Circesium (Assyrian Sirki), modern Al-Buseira. The fortress on the opposite bank, Salahiya (Ad-Daliye of Arab times) lies a little below. Between this point and Deir, on an old canal are the ruins of the Arab fort of Rahba.

Although some doubts have been raised there seems every probability that the Khabur is identical with the Araxes of Xenophon (called Saccoras by Ptolemy) and the distance given by Xenophon, of fifty parasangs between Thapsacus and Araxes, is a fair estimate of the actual distance. All this northerly region must have been until the time of the Mongols, or even later fairly highly populated and prosperous, both on the evidence of archaeology and the statements of ancient authors. It seems probable that the change is due entirely to the devastating effect of the Mongol invasion.

Below this point the region has always been desolate, although along the river in ancient and modern times there were a series of small towns and villages. Below Salahiya on the eastern side of the river are the ruins of Al Irsi and below this again, at a point where two great wadis mark the course of a former tributary from the Syrian plateau, is an unidentified town built of unbaked brick. At this point there is a sharp bend to the east as far as Ana, above which town are a series of rapids. Ana is an ancient town, probably originally Sumerian; it lay on islands of the stream, where there are today a series of ruins, mostly of Persian and Arab date. The whole nature of the river changes at this point, the valley is very constricted, leaving very little alluvial ground for cultivation, while there are numerous islands in the stream. The vegetation also changes. Although the date palm grows as far north as Deir, here it becomes common and in favoured spots palm groves are found, while the olive, characteristic of the Mediterranean regions, entirely disappears. Side by side with the change in flora the presence of one ruin at least of crude brick, shows that we are definitely approaching the true Mesopotamian zone.

Between Ana and Hit there are four ancient sites, possibly old river guard posts. Haditha, in ancient times Baia Malcha, was an important town under the Abbasids; Al Uzz may probably be identified with the ancient Auzura (Uzzanesopolis) and Jibb Jibba, a site whose ancient name has not been identified. Olabu lies on the now uninhabited island of Telbeis. The neighbourhood of Hit is remarkable for the bitumen lakes, which supplied material for cementing bricks in ancient times and was and is still used for caulking boats. The region has been known from time immemorial as a place where there was an ooze of petroleum and it is possible that it may prove a fertile oil field.

The whole of the region of the middle Euphrates is marked by a long series of ancient sites. In classical times it was comparatively thickly populated and the descriptions of Xenophon suggest that the country was fertile and contained much game. Until the Mongol invasion this prosperity continued, and indeed there is reason to believe that it attained its greatest prosperity under the Abbasid caliphs.

The Lower Division.—The lower division of the Euphrates extends from Hit to the junction with the Tigris, just below Kurna. Throughout this region the river runs through bare flat alluvium in a south-easterly direction, with little traces of any rock except just above Hilla and at Warka. At Hit the river is about 250 yd. across. From this point onwards the river decreases in size, as it receives no tributaries and much of its water is used for irrigation or dissipated in swamps. The speed of the main stream is slow, not normally exceeding a mile per hour and often falling to a quarter of this velocity except where the stream is held up by floating bridges, as at Ramadi, Feluja, Mussaib, Hilla, Diwaniya and Samawa. From Hit to Museyib there is a single channel. Between the latter town and Samawa the Euphrates divides into two branches: the more westerly, which carries most of the water, the Hindiya branch; the more easterly the Hilla branch. At Feluja the river approaches most closely to the Tigris, but from that point onwards the two streams are widely separated and enclose the great alluvial plain of ancient Sumeria.

All this region is extensively irrigated and the canals supplied by the river form an important part of its topography. Of these canals the largest is the Cherra Saaheh (Khandak Sabur). This great canal ran all along the edge of the alluvial plain from below Hit to the Persian gulf. It was protected by a series of guard posts and is of great antiquity; it was reconstructed in the time of Nebuchadrezzar, but its original date is unknown. The majority of the canals however are on the left bank, and originally tailed into the Tigris. Above Ramadi, a small town which forms the crossing place of the modern mail service across the desert, the Dujail flows across the plain and into the Tigris between Ukbara and Baghdad. Below this the Sakhlawiya, which follows closely the course of an ancient canal, leaves the Euphrates near Anbar and joins the Tigris at Baghdad. This canal had within the last sixty years been navigable for steamers. Below this again the Abu-Ghuruayb (Sarsar) crosses the plain and tails into the Tigris between Baghdad and Ctesiphon. The Nahr al Mali, sometimes called to-day the Radhwaniya canal, a little lower down joins the Tigris below Ctesiphon. Below this the Cutha canal Harl Ibrahim crosses the narrow strip between the rivers. It will be seen from an enumeration of this series how important to Mesopotamia the close position of the two rivers is and what profound changes have been effected by the alteration of the bed of the Euphrates lower down the stream.

Below Museyib the river has from ancient times divided into two branches, the Hindiya and the Hilla branch. The ancient channel however seems to have flowed still more to the east, past a series of ancient sites of which the most important are Kish and Nippur, below which it again divided into two channels. (*See* MESOPOTAMIA: *Ancient Geography.*) The two modern branches join again near Samawa, 110 m. lower down. Between 1865 and 1890 the main stream shifted its course into the western branch. The Hilla branch was threatened with complete desiccation. A new Hindiya barrage was erected and a regulator was built on the Hilla branch to ensure a proper distribution of the water. Considerable progress is being made in this region in restoring the ancient irrigation system. The Shatt al Nil, a canal which probably followed more or less the ancient stream bed, is once more in use and is irrigating a large amount of land; it runs quite close to the ancient city of Kish. Near Diwaniya there is also another large canal.

On the Hindiya branch there are no important towns, on the Hilla branch is Hilla itself, lying on both sides of the river, the

two banks being connected by a bridge of boats; below is Diwaniya. At Samawa the two branches reunite and flow to Nasariyeh. From this point onwards the Euphrates is lower than the Tigris. Nasariyeh probably marks the spot where at one time the two rivers joined. The Shatt al Hai, which flows along the old bed of the Tigris, even to-day carries a good deal of Tigris water into the Euphrates and was carrying the main stream certainly down to 2000 B.C. From this point onwards it flows through marshy land and eventually joins the Tigris at Kurna. From this point onwards the united streams are known as the Shatt al Arab (*q.v.*).

From Hilla onwards there are no ancient sites on the present course of the Euphrates, though Ur is close to the stream. Considerable discussion has taken place concerning the place where the Euphrates flowed into the sea in ancient times. There is absolutely no doubt that the ancient texts definitely state that Eridu was on the edge of salt water. If it be argued that it was on the edge of a lake this lake must have been salt, unless we are to disregard the ancient statements. Campbell Thomson's discovery of fresh water mussels has been put forward as proving that the ancient texts must be disregarded. His account however does not disprove that the mussels in the earliest stratum were in situ and had not been used for food. Some sea shells were also found, which may equally well have been used for food. In later times the abundance of fresh water shells on the surface shows that the area must have been a large lake. There is further evidence of numerous lacustrine lakes along the Euphrates; in classical times there was one as high up as Karbala. To-day such lakes as exist have become marshes. The river is however still young and has not yet firmly established itself in its channel. The deposition of silt will probably in time accomplish this. The point however is an important one, for naturally on the amount of silt which the river can deposit on its way to the sea will greatly depend its power of adding to its delta at the mouth.

Navigation.—Although high water may be said to extend from Dec. to June, the river does not begin to rise high till the end of March, attaining its maximum about the end of May, and its minimum at the end of November. In ancient times there seems to have been considerable traffic on the river, practically all down stream. Much of the modern traffic, both in the forms of the boats and in methods of navigation, does not differ very much from the ancient methods. From Meskene to Hit the local traffic is carried downstream in flat bottomed boats. Much of the river is interrupted by rapids and navigation is difficult except at high water. Below Hit the river can be navigated by steamers with a draught of under 5 feet. The width of the stream varies between 150 and 500 yd., with a current of 5 m. an hour, draining to 1½ at low water. The discharge at Hit varies from 4,000 cu. metres a second to as low as 270. The observations on the Hindiya branch are too few to furnish a just estimate; no continuous navigation can be carried on in the Hilla branch. In the Hindiya branch there are locks planned to take vessels drawing 5 ft. at low water, but at the barrage and Samawa at certain times only 2 ft. is available. South of Samawa, between this town and Nasariyeh the river flows in a firm bed and a minimum of 5 ft. is always available and there are no obstacles to navigation. Below this point the river is no longer navigable except in flood time.

The main channel below Suk esh Sheyuk no longer carries any large amount of water and the Euphrates discharges through the Hammar lake to the Shatt al Arab at Kurmat Ali. During the World War certain efforts were made to dredge the old channel and to cut through the bar at Chubaish, but these were discontinued and a large expenditure would no doubt be necessary to make navigation possible along the whole stream. Sir W. Willcocks proposed to use the river purely as a drain for the water used for irrigation from the Tigris. Considerable divergence of opinion has been expressed on this point, and some authorities have considered that the river might be used for both purposes, although considerable works might have to be undertaken. In the lower reaches of the river no doubt considerable maintenance charges would be needed. It has been considered that, if the obstacles up stream were removed and a different method of irrigation employed, the upper reaches could be used for up stream as well as down stream navigation, which in time might be commercially profitable.

(L. H. D. B.)

EUPHRONIUS, a distinguished Athenian potter and vase painter of the end of the sixth and beginning of the fifth century B.C. (*see* GREEK ART and CERAMICS). Several vases with his signature are preserved. The name of the artist who decorated the vases which Euphronius signed as potter is not known, but he has been named the Panaitios painter from the inscriptions "fair Panaitios" which occur on his works. Among the best known vases decorated by Euphronius as painter are the crater with Heracles and Antaeus (Louvre) and the Kylix with Heracles and Geryon (in Munich). (*Cf.* J. D. Beazley, *Attische Vasenmaler,* pp. 58 ff. and 165 ff., 1925.)

EUPHROSYNE (*fl. c.* 470), a virgin of Alexandria, who, to escape marriage, disguised herself as a man and became a member of a monastic community. In his grief her father came to her for religious instruction, but she did not reveal her identity until just before her death. Her feast is celebrated in the Roman Church on Jan. 16, and in the Greek Church on Sept. 25.

EUPHUISM, the peculiar mode of speaking and writing brought into fashion in England towards the end of the reign of Elizabeth by the vogue of the fashionable romance of *Euphues,* published in 1578 by John Lyly. As early as 1570 Ascham in his *Schoolmaster* had said that "Euphues" (*i.e.*, a man well endowed by nature, from the Gr. εὖ, φυή well, growth) is "he that is apt by goodness of wit, and applicable by readiness of will, to learning, having all other qualities of the mind and parts of the body that must another day serve learning." Lyly adopted this word as the name of the hero of his romance, and it is with him that the vogue of Euphuism began. He addressed himself to "the gentlewomen of England," and he had the audacity, in that grave age, to say that he would rather see his books "lie shut in a lady's casket than open in a scholar's study." Lyly was 26 when he published in 1579 the first part of *Euphues: the Anatomy of Wit:* a second part, entitled *Euphues and his England,* appeared in 1580.

For a comprehension of the nature of Euphuism it is necessary to remember that the object of its invention was to attract and to disarm the ladies by means of an ingenious and playful style, of high artificiality, which should give them the idea that they were being entertained by an enthusiastic adorer, not instructed by a solemn pedagogue. For 50 years the romance of *Euphues* retained its astonishing popularity. As late as 1632 the publisher, Edward Blount (1560?–1632), recalling the earliest enthusiasm of the public, wrote of John Lyly, "Oblivion shall not so trample on a son of the Muses, and such a son as they called their darling. Our nation are in his debt for a new English which he taught them. *Euphues and his England* began first that language. All our ladies were then his scholars, and that beauty in Court, which could not parley Euphuism, was as little regarded, as she which, now there, speaks not French." Among those who applied themselves to this "new English," was Queen Elizabeth herself, styled by J. R. Green "the most affected and detestable of Euphuists."

Euphuism did not attempt to render the simplicity of nature. On the contrary, in order to secure refinement, it sought to be as affected, as artificial, as high-pitched as possible. Its most prominent feature was an incessant balancing of phrases in chains of antitheses, thus:— "Though the tears of the hart be salt, yet the tears of the boar be sweet, and though the tears of some women be counterfeit to deceive, yet the tears of many be current to try their love." Another of the main characteristics of Euphuism was the incessant use, for purposes of ornament, of similes taken from fabulous records of zoology, or relating to mythical birds, fishes or minerals. This was a feature which was excessively admired. That lady was considered most proficient in Euphuism who could keep up longest these chains of similes taken out of fabulous

natural history. Alliteration was also a particular ornament of the Euphuistic style, as: "The bavin, though it burn bright, is but a blaze," but the use of this artifice by Lyly himself was rarely exaggerated; for instances of its excess we turn to his imitators.

The earliest instance of the word "Euphuism" which has been traced occurs in a letter written by Gabriel Harvey in 1592, when he speaks of a man, who would be smart, as talking "a little Euphuism." Dekker, in the *Gull's Hornbook* of 1609, uses the word as an adjective, and denounces "Euphuised gentlewomen." When the practice was going out of fashion we find it thus severely stigmatized by Michael Drayton, a poet who had little sympathy with the artificial refinement of Lyly. In an elegy, printed in 1627, Drayton refers to the merit of Sir Philip Sidney, who recalled English prose to sanity, and

"did first reduce
Our tongue from Lyly's writings then in use,
Talking of stones, stars, plants, of fishes, flies,
Playing with words and idle similes,
As th' English apes and very zanies be
Of everything that they do hear and see,
So imitating his ridiculous tricks
They spake and writ, all like mere lunatics."

This severe censure of Euphuism may serve to remind us that hasty critics have committed an error in supposing the *Arcadia* of Sidney to be composed in the fashionable jargon.

Lyly found in Greene, Lodge, Dickenson, Nicholas Breton and others, enthusiastic disciples who had learned all the formulas of Euphuism, and could bring them forth as fluently and elegantly as he could himself. Nevertheless the trick wore out, with the taste that it had created, by the close of the reign of James I.

Critics have not failed to insist, on the other hand, that a species of Euphuism existed before *Euphues* was thought of. It has been supposed that a translation of the familiar epistles, or, as they were called, the "Golden Letters," of a Spanish monk, Antonio de Guevara, led Lyly to conceive the extraordinary style which bears the name of his hero. Between 1574 and 1578 Edward Hellowes (fl. 1550–1600) translated into a very extravagant English prose three of the works of Guevara. Earlier than this, in 1557, Sir Thomas North had published a version of the same Spanish writer's *Reloj de Principes* (The Dial of Princes), a moral and philosophical romance not without a certain likeness in plan and language to *Euphues*.

See Landmann, *Der Euphuismus* (1881); Arber's edition of *Euphues* (1869); R. W. Bond's *Complete Works of Lyly* (1902).

EUPOLIS (*c.* 446–411 B.C.), Athenian poet of the Old Comedy, flourished in the time of the Peloponnesian War. He is said to have been drowned by Alcibiades, whom he had attacked in one of his plays, but it is more likely that he died fighting for his country. He is ranked by Horace (*Sat.*i.4.1) along with Cratinus and Aristophanes, as the greatest writer of his school. He was reputed to equal Aristophanes in the elegance of his style and Cratinus in his command of satire. Although he was at first on good terms with Aristophanes, their relations later became strained, and they accused each other of plagiarism. Of the 17 plays attributed to Eupolis, with which he won the first prize seven times, only fragments remain. Of these the best known were: the *Kolakes*, directed against the spendthrift Callias (*q.v.*); *Marikas*, an attack on Hyperbolus, the demagogue; the *Baptai*, against Alcibiades and his clubs. The *Demoi* and *Poleis* were political, dealing with the desperate condition of the state and with the allied (or tributary) cities.

Fragments in T. Kock, *Comicorum Atticorum fragmenta*, i. (1880).

EUPOMPUS, the founder of the great school of painting which flourished in the 4th century at Sicyon in Greece. He was eclipsed by his successors, and is chiefly remembered for the advice which he is said to have given to Lysippus to follow nature rather than any master.

EURASIAN, a term originally used in India to denote children born of Hindu mothers and European (especially Portuguese) fathers. Following the geographical employment of the word Eurasia to describe the whole of the great land mass of Europe and Asia, Eurasian is used of persons born of parents representing the races of the two continents.

EURE, a department of north-western France, formed in 1790 from a portion of the old province of Normandy, together with the countship of Evreux and part of Perche. Pop. (1926) 308,445. Area, 2,330 sq.m. It is bounded north by the department of Seine Inférieure, west by Calvados, south-west by Orne, south by Eure-et-Loir, and east by Seine-et-Oise and Oise. Eure is a dissected plateau sloping from a height of 800 ft. in the south-west to the Seine in the north. Forests cover about one-fifth of the department. The rivers include a portion of the Seine in the north-east, receiving the Andelle and the Epte on the right, and the Eure with its feeders the Avre and the Iton, and the Risle with its tributary the Charentonne, on the left. The Eure and the Risle rise in Orne. The climate is mild, but moist and variable. The soil is for the most part clayey, resting on a bed of chalk, and is, in general, fertile and well tilled. Wheat, oats, colza, flax and beetroot are grown. There is much pasturage, supporting numbers of cattle and sheep, and especially of the celebrated Norman horses. Fruit is very abundant, especially apples and pears, from which much cider and perry are made. The mineral products of Eure include freestone, marl, lime and brick-clay. The chief industries are the spinning of cotton and wool, and the weaving, dyeing and printing of fabrics of different kinds. Turnery, cotton-bleaching, metallurgy, tanning, and the manufacture of glass, paper and wind instruments are also carried on. Coal and raw materials for its industries are the chief imports of Eure; its exports include cattle and horses, poultry, eggs, butter, grain and manufactured goods. The department is served chiefly by the Ouest-État railway; the Seine, Eure and Risle provide 87 m. of navigable waterway. Eure is divided into the following arrondissements (containing 36 cantons, 700 communes):—Evreux, Les Andelys and Bernay. The capital of the department is Evreux, which is the seat of a bishopric of the ecclesiastical province of Rouen. The department belongs to the III. Army Corps (Rouen) and to the *académie* (educational division) of Caen. Its court of appeal is at Rouen.

Evreux, Les Andelys, Bernay, Louviers, Pont-Audemer, Verneuil, Vernon and Gisors are the principal towns of the department. At Gaillon there are remains of a celebrated château of the archbishops of Rouen (*see* LOUVIERS). Pont de l'Arche has a fine Gothic church, with stained-glass windows of the 16th and 17th centuries; the church of Tillières-sur-Avre is a graceful specimen of the Renaissance style. The churches of Conches (15th or 16th century) and of Rugles (13th, 15th and 16th centuries), and the château of Beaumesnil (16th century) are also of architectural interest.

EURE-ET-LOIR, an inland department of north-western France, formed in 1790 of portions of Orléanais and Normandy. Pop. (1926) 255,213. Area, 2,293 sq.m. It is bounded N. by the department of Eure, W. by Orne and Sarthe, S. by Loir-et-Cher, S.E. by Loiret, and E. by Seine-et-Oise. The Perche in the south-west and the Thimerais in the north-west are districts of hills and valleys, woods, lakes and streams. The level cornland of Beauce occupies the east and south. The department is drained northward by the Eure (tributaries Vègre, Blaise and Avre), and southward by the Loir (tributaries Conie and Ozanne). The air is pure, the climate mild, dry and not subject to sudden changes. The soil is either clay intermixed with sand or porous calcareous earth, and is on the whole fruitful. Wheat and oats are highly cultivated on the Beauce. Barley, beetroot and other vegetables, including good asparagus, are grown. Cider apples are produced abundantly in the Perche. A large number of cattle and sheep are raised and also draught horses in the Perche. Bee-farming is commonly carried on. The department produces building-stone, lime, grindstones and brick-clay. The manufactures are not extensive; but there are flour- and saw-mills, tanneries and leather-works, copper and iron foundries, starch-works, dye-works, distilleries, breweries and potteries; and agricultural implements, cotton and woollen goods, and yarn, hosiery, boots and shoes, sugar, felt hats and paper are made. Eure-et-Loir exports the products of its soil and live-stock; its imports include coal, wine and wearing apparel. It is served by the railways of the Ouest-Etat, the Etat and the Orléans company, but it has no navigable waterways. The department has Chartres for its capital, and is divided into the

arrondissements of Chartres, Châteaudun and Dreux. There are 24 cantons and 426 communes. Eure-et-Loir forms the diocese of Chartres (province of Paris), and belongs to the académie (educational division) of Paris and the region of the IV. Army Corps (Le Mans). Its court of appeal is at Paris.

Chartres, Dreux, Châteaudun, Nogent-le-Rotrou and Anet are the more noteworthy places in the department. At Bonneval the lunatic asylum occupies the 18th century buildings of a former Benedictine abbey. The abbey church belonged to the 13th century, but only a gateway flanked by two massive towers is left. The château of Maintenon, 16th and 17th centuries, was presented by Louis XIV. to Madame de Maintenon, by whom additions were made. St. Lubin-des-Joncherets has a handsome church of the 11th century, in which there are 16th century stained-glass windows.

EUREKA, a city of California, U.S.A., 294m. N. by W. of San Francisco, on Humboldt bay, 2m. from the ocean; a port of entry, the county seat of Humboldt county and the most western city in the United States. It is on the Redwood highway; is served by the Northwestern Pacific railway; and is a division point for the Pickwick stages, operating over the highway from San Francisco to Grant's Pass, Oregon. The population was 12,923 in 1920 (24% foreign-born white), and was estimated locally at over 19,000 in 1928. Eureka is in a magnificent stand of redwood timber. Enormous quantities of redwood lumber are made in the saw-mills, and shipped largely to San Francisco, Hawaii, Australia and the Orient. Humboldt bay is the largest landlocked harbour between San Francisco and the Columbia river. Its traffic in 1927 amounted to 670,540 tons, valued at $24,927,773. At Arcata, on the northern arm of the bay, is the Humboldt State teachers' college. The Hoopa Valley Indian Reservation is 53m. N.E. by highway. When Humboldt county was organized (1853) Eureka was already the centre of an important lumber trade, chiefly in spars. The city was incorporated and became the county seat in 1856.

EUREKA SPRINGS, a city of north-western Arkansas, U.S.A., in the Ozark mountains, 1,500–2,000ft. above sea-level; one of the county seats of Carroll county. It is served by the Missouri and North Arkansas railway. The resident population was 2,429 in 1920, but there is a transient population averaging 3,500 daily in summer, and half as many throughout the year. Eureka Springs is one of the oldest health and pleasure resorts of the Ozarks. It is built on the slopes and crests of several mountains, streets and buildings rising terrace-like one above another. There are two bath-houses, a well equipped hospital, numerous hotels, apartment houses and furnished cottages. The springs are held in trust by the city for the free use of the public. The water is radio-active; varies in temperature from 57° to 64° F; contains 28·5 cu.in. of gaseous matter per gallon and 6 to 9 grains of solids held in solution, and is especially beneficial in diseases of the kidneys. There is good fishing in the neighbouring streams, and Lake Lucerne, fed by springs, is a beautiful resort 2m. distant. The first settlement here was made in 1879 and the city was chartered in 1880.

EURHYTHMICS is the term applied generally to the use of harmonious bodily movement as a form of artistic expression, and specifically to Dalcroze's system of musical education which is founded on a rhythmical discipline of bodily movements for the expression of time values. The present article is restricted to the latter sense. (*See* DANCING.)

History.—Émile Jaques Dalcroze (b. 1865) studied music at the Geneva Conservatoire and under Delibes in Paris and Bruckner and Fuchs in Vienna. In 1892 he was appointed professor of harmony at Geneva Conservatoire. His experience as a teacher suggested to him that the conventional professional training of musicians was radically wrong in that it ignored the relation of technical training to the inner consciousness of the student. He argued that the student should begin not by specializing on any instrument, but by developing his musical faculties as a basis for specialized study. Such a training could only be secured by awakening the sense—natural, though often latent—of the ultimate bases of music, viz., tone and rhythm.

As the sense of tone can be developed only through the ear, Dalcroze gave special attention to vocal work; and then, noticing that when the students themselves beat time to their singing the work became much more real, he wrote a series of "gesture songs," which were performed by his pupils with surprising ease. This suggested the idea which is the essence of the Dalcroze method, viz., the training of the body in such a way as to make movement not merely an accompaniment of music, but a means of expressing it.

About 1905 Dalcroze began to consider the possibility of applying his method not only to the special education of musicians but as part of the general elementary education of children. Accordingly he worked out a system of pedagogic eurhythmics, which has been widely adopted in schools throughout Europe and America.

Outline of the Method.—The Dalcroze method consists of three parts: (*a*) rhythmic movement, (*b*) ear training and (*c*) improvization (practical harmony). Of these the first is the essence of the Dalcroze method and is fundamentally new. The second is closely linked with the first and necessary to the pupil. The third is necessary to the teacher.

In the system of exercises upon which the method is based, *time* is shown by movements of the arms, and *time-duration, i.e.,* note-values, by movements of the feet and body. In the early stages of the training this principle is clearly observed; later it may be varied in many ingenious ways—for instance, in what is known as plastic counterpoint the actual notes may be represented by movements of the arms, while the counterpoint in crotchets, quavers or semiquavers is given by the feet.

In the series of movements to represent note-values the crotchet is taken as the unit—this is represented by a step; higher values, from the minim to the note of 12 beats, are represented by a step with one foot and a movement or movements with the other foot or with the body, but without progression; *e.g.,* a minim by one step and a knee bend, a dotted minim by a step and two movements without progression, a note of 12 beats by a step and 11 movements. Thus for each note in the music there is one step, one progression in space, while at the same time the note, if of greater length than a crotchet, is analysed into crotchets. Notes of shorter duration than a crotchet, *i.e.,* quavers, triplets, etc., are expressed also by simple steps.

The whole training aims at developing the power of rapid physical reaction to mental impressions. These latter are more commonly obtained through the ear, chiefly from the music played; naturally, however, the teacher needs at times to give commands during an exercise. For this purpose he generally uses the word "hopp," chosen for its clear incisiveness. Before each exercise it is clearly stated what the word is to represent in that particular case, *e.g.,* omit one beat, omit one bar, beat time twice as fast as with the arms, etc.; often the word will be used in series in an exercise, each "hopp" meaning some additional change. As the command generally falls on the second half of the beat preceding the one in which the change is to be made, very rapid intellectual and physical response is necessary, especially if the music be at all quick. Exercises of this class soon give the power of rapid muscular innervation and inhibition, and are of extraordinary value in education, quite apart from their purely rhythmic side. (P. B. I.)

EURIPIDES (*c.* 484–407), the third of the great Greek tragedians, apart from his success as a playwright—he held the stage for 600 years—is a figure of much significance in human history. The date of his death can be fixed. He produced the *Orestes* in 408 B.C., but was dead before Aristophanes began writing the *Frogs* (produced Jan. 405 B.C.) and before the Dionysia of March 406, when we hear that Sophocles, in the Proagon, brought his Chorus on without garlands in mourning for his great rival. His year of birth, however, as usual with famous men in antiquity, seems to have been a matter of conjecture. One tradition groups the three tragedians round the battle of Salamis in 480 B.C.: Aeschylus fought in the ranks, Sophocles danced in the Boys' Chorus, Euripides was born. This has the air of a Hellenistic literary "combination," more convenient to the memory than strictly historical. More authentic perhaps is the date given by

the Parian Marble, 484 B.C.; though, since that chronicle (inscribed 264 B.C.) puts for 484: "Euripides born; Aeschylus' first victory," and for 455 "Aeschylus' death; Euripides' first production," this dating also may be a "combination." At any rate he must have been over 20 by the time of that first production; and this may be the ground of the statements of Philochorus that he was "more than 70," and Eratosthenes that he was "75" when he died.

Euripides has had always a chequered fate. During his life he was famous throughout Greece, but won only four first prizes out of 22 competitions. He was incessantly assailed by the comedians, especially by Aristophanes in the *Acharnians* (423), the *Thesmophoriazusae* (411), which is largely made up of parodies of Euripides, and the *Frogs* (405), which contains an elaborate comparison of his art with that of Aeschylus. Yet an obvious liking and admiration enter into the ridicule, and the attacks are not quite consistent with one another. He is too realistic, dressing his exiled kings in rags; he is too romantic, with his disguised princes and inspired princesses. His heroes talk the language of common life: his diction is all tragic tags. He is an unbeliever, rejecting the gods and worshipping Aether or Intelligence; he is an unintelligible mystic with his doctrine that "Life is not life." He is too austere; he is dangerously immoral. His lyrics are parodied—and beautifully parodied—partly for metrical licences, partly for their extreme melodiousness. The fact is that Euripides, as Aristophanes repeatedly says, was essentially σοφός, and σοφία was a word of wide range. His intellect broke the bounds of custom not in one direction but in many.

Similarly in modern times he is apt to be treated almost as a personal enemy by the type of scholar which dreads unorthodoxy or which dislikes elaborate clarity (σαφήνεια) of style: while by another he is idealized for the most various and contradictory reasons: as a rationalist, a realist, a mystic; as the inventor of romance; as a dramatist who ought to have written in prose, as a great lyric poet who cared little for drama. Elmsley remarks that he is "marvellously addicted to contradicting himself"; Swinburne calls him "a botcher"; Schlegel treats him as the wrecker of Greek classic poetry; while Aristotle, in spite of serious criticisms in detail, calls him "the most tragic of the poets." Milton profoundly admires him, and Goethe asks indignantly whether all the nations of the world since his time have produced one playwright worthy to hand him his slippers.

This striking discord of opinion goes back to a discord in the poet himself. Euripides was a child of that great intellectual awakening which made 5th century Athens a new era in the history of mankind. There arose after the Persian War a widespread realization of the value of σοφία, "wisdom" or "knowledge," with its companion ἀρέτη, "virtue," and concomitantly a whole generation of "educators" or *Sophistae,* ready to make men wise in all the varieties of wisdom: science, music, art, poetry, history, philosophy or politics. Euripides is said to have been a pupil of Anaxagoras, who had proved the existence of air as a substance, taught that the sun was not a god but a mass of incandescent metal, incredibly large; that the order in the universe was produced by Mind or Thought (Νοῦς). He was a close friend of Protagoras who confessed that he knew nothing about the gods; studied the principles of language and of human society; emphasized the distinction between Nature (Φύσις) and Custom (Νόμος) and the extreme relativity of all human judgements. And we are told that Socrates himself never went to the theatre unless there was a play by Euripides; then he would walk as far as the Pairaeeus to see it.

Thus Euripides belonged to the *sophoi,* and his *sophia* startled the old-fashioned Athenian now in one way and now in another. At the same time the art at which he worked was the most rigid and old-fashioned of all the great arts. A painter or sculptor or lyric poet was, comparatively speaking, free. But a tragedian could choose neither his form nor his subject. He must compose in a traditional pattern, based on a religious ritual and exhibited on the festival of Dionysus under the presidency of his priest; his subject is always some traditional story of heroes or gods, and is mostly a representation of the origin of some religious rite, the Torch-race at the Prometheia, the Burial of Ajax at the Aianteia, the mourning service for Hippolytus, etc.

The clash is obvious. Indeed to an Englishman there is danger of overemphasizing it. For we must remember that questions of personal belief or unbelief mattered little in the ancient world. Religion was chiefly a matter of ritual or practice, and Euripides himself held, probably as an ancestral privilege, the positions of "fire-bearer" and "cup-bearer" in the worship of the Delian Apollo. Nevertheless there was evidently a certain conflict between the poet's audacious questioning and original mind and the stately and antique art-form in which he laboured.

Qualities of his Art.—As an artist he seems to have liked formality. In Sophocles we can see a movement towards naturalness in language and composition. There is sometimes elision at the end of the verse; there is variety in the length of speeches in dialogue; there is much colloquial idiom. In Euripides there is a return to formality. With all his variety of invention and his resolute sincerity in the treatment of character, he keeps more closely even than Aeschylus to the art-form imposed by the ancient Dionysiac ritual (*see* DRAMA: *Greek*). His matter, so to speak, is not conventionalized, but his form is. Each play, as a rule, opens with one solitary figure, generally supernatural or half-supernatural, in the darkness before dawn, speaking a prologue. One thinks of the *prorrhesis* spoken by the hierophant before a sacred ceremony. Artistically this serves an important purpose. It makes the atmosphere and starts the play in extreme dignity and quiet. Thereafter carefully, by set stages, the action quickens, rises to climax after climax, and then sinks again to calm in the last scene. That last scene is often like the first. In about half the plays it contains the epiphany (generally on a *machina* in the air) of a god or goddess who calms the strife, explains or half-explains the mystery, reconciles the combatants, of the play itself, and by foretelling the future fates of the characters gradually brings the performance down from the stir of drama to the calm of narrative. This peaceful end, or καταστροφή, was almost essential in Greek art. Later ages, which liked a bustling first scene and a "strong curtain" have been puzzled by the prologue and *deus ex machina,* and have imagined that they were mere mechanical expedients by which an unskilful dramatist contrived to "cut the knots" of his story. The view is unhistorical and untenable; in scarcely any case is the theophany really used to "cut a knot": in some cases (e.g., *Iph. Taur.* 1,394 ff.) a difficulty is invented in order to give an excuse for the theophany.

Another element in the ritual of the dying Year God, is highly developed in Euripides, viz., the messenger who announces the πάθος. His entrance is carefully prepared, so as to keep us hanging on his words. His speech is a formal recitation, constructed on rhetorical principles and highly effective on the stage, but with no attempt at "naturalness." The scenes of dialogue, again, are formal. There is seldom any ordinary conversation. (The one fragment of prose from the blinded Thracian in the Hecuba [1,091 ff.] seems to aim not at realism but at an artistic shock.) There are scenes in which long speech answers long speech, each closed by two formal lines of Chorus with an effect like a chord of music; and there are scenes in which single line answers single line, like the clashing of swords. This highly wrought form was part of the poet's σοφία.

Most significant of all, the Chorus, which in Aeschylus' earliest plays occupied half the performance and was reduced by Sophocles in the *Oedipus Rex* to less than one-fifth, increases again in the later plays of Euripides, both in length and in importance. In the *Troades* and *Bacchae* the Chorus is practically protagonist. By realistic standards of course the Chorus is grotesquely undramatic, and Sophocles had tactfully minimized its obtrusiveness. By other standards it is not only the rock out of which tragedy was hewn, it has a beauty and dramatic power which are all its own. Euripides uses it for all it is worth, casting aside verisimilitude for the sake of something greater.

The Chorus is sometimes described as "an ideal spectator." This means that it is there to express, in music and yearning of the body, an emotion which is not the emotion of one particular person at one moment of the play but something more impersonal

and eternal. Examples would be the Ocean Spirits in Aeschylus' *Prometheus,* expressing the anguish of the world; the Bacchae of Euripides with their mystic worship; the Trojan women, like "half-heard voices of an eternal sorrow"; or the Old Men who dream dreams in the *Heracles.* The Chorus in Euripides often seems to float, as it were, between earth and heaven. Sometimes they bring comfort to us from that world of music where "metaphor, as we call it, is the very stuff of life"; at times by some intensity of emotion they are shaken into personal life and feeling: as when at the child-murder in the *Medea* they beat vainly against the barred door.

This strictness of convention in part emphasizes the conflict of which we have spoken, in part it lifts the poetry above it. The conflict is by no means all to the bad. The artistic flaw was often compensated by a gain in depth, in observation and in passion. Euripides' revolt against custom took various forms. At one time he would make a strangely ingenious and adventurous plot (*Telephus**, *Ph. Aul.*); at another he would raise problems of morality or religion (*Bellerophontes**, *Cressae**, *Heracles*); he would make use, austere by our standards but fuller than any previous dramatist, of the motive of love (*Andromeda**, *Hippolytus*), sometimes in abnormal forms (*Cretes**, *Aeolus**); he would study the intrigues and vindictiveness of political strife (*Orestes, Andromache*); or again he would deal with the wrongs and revenges of woman, or the madness of war (*Medea, Troades*). Sometimes he would take a heroic story as it stood, and show not its heroic quality but its barbarity (*Electra*).

This variety of creative imagination explains, so far as it needs explanation, the great variety of philosophic statements or *gnomae* which can be found in Euripides, and which cause him to be such a frequent source of quotations. There is of course no inconsistency in making one hero, when staggered by the injustice of the world, exclaim: "There are no gods!" (frag. 286), and another, in a different situation, comment on the folly of the man who denies the gods. But Euripides does seem to take the full licence of a dramatist in letting his thoughts run strongly first in this direction and then in that. A dramatist illustrates his problems; he is not bound to commit himself to a decision about them.

His Life.—An anonymous and shapeless *Life and Race of Euripides* is found, in varying forms, in some of the mss. It is derived from earlier sources, notably from a *Life* by Satyrus, an Aristotelian of the later 3rd century B.C., and an *Attic Chronicle* by the rather earlier antiquarian, Philochorus. A considerable fragment of Satyrus discovered on a papyrus in 1911 enables us to see how unhistorical most of the anecdotic tradition is. Much of it is made up simply of the inventions of comedy treated as facts. Thus, the plot of the *Thesmophoriazusae* (in which the women at their secret festival plot to murder Euripides, because he has so "shown them up" on the stage and he sends his hirsute father-in-law disguised among them as a spy) is seriously repeated as history by Satyrus, Gellius, and the *Life.* Equally fictitious must be the story that he had two wives, like his own Neoptolemus, and that both deceived him, like his own Aerope. In the *Thesmophoriazusae,* produced when he was 73, he is still married to his first wife, Melitê, and there is no hint of matrimonial trouble. Neither need we believe that he was torn in pieces by hounds, like Actaeon, or by wild women, like Pentheus. We know from Philochorus that his mother Cleito, was "of very high family"; but for some reason it was a recognized joke to say she was a greengrocer and sold inferior greens. This may come from a much-quoted line in *Melanippe the Wise**: "It is not my word but my mother's word," the said mother being an authority on magic herbs and simples. Turn the heroine's mother into the poet's mother, and the potent herbs into "wild cabbages," and the fable is made.

For reliable information even Philochorus, our best authority, must have been poorly off. He had no collection of letters and papers, like a modern biographer. He would have the public records of the plays performed at Athens year by year; he might find a few mentions of Euripides in odd inscriptions. If he wrote about 300 B.C. there was no one living who could remember a man who died in 406 B.C. There might at most be men of 70 whose fathers had spoken to Euripides and whose grandfathers had known him well. Such memories as we have are all about the poet's old age, and all very external. He wore a long beard and had moles on his face. He lived much alone and hated society. He had crowds of books and did not like women. He lived in Salamis, in a cave with two openings and a beautiful sea view, and there you could see him "all day long, thinking to himself and writing, for he simply despised anything that was not great and high."

*An asterisk denotes a lost play.

He was the son of Mnesarchus or Mnesarchides, a merchant, and born at Phlya, a village in the centre of Attica, a seat of temples to Demeter, Dionysus and the Dread Goddesses, and a mystery cult of Eros. If born in 484, he would be about eight when the ruined walls of Athens were rebuilt after the Persian invasion; at 12 he may have seen Aeschylus' *Persae;* at 17 he pretty certainly saw that poet's *Seven against Thebes* and was much influenced by it. In 466 he began his military service with garrison duty in frontier forts, and while his spear and shield were still new received the news of the massacre of 10,000 Athenian settlers by the Thracian tribes of the Strymon. No wonder one of his earliest plays was about *Rhesus,* the Thracian hero.

His First Plays.—We hear that he was an athlete; he won prizes both in Athens and Eleusis. He also painted; and paintings by his hand were found by later antiquarians in Megara. His first play was performed in 455 B.C., on the *Daughters of Pelias**, who were led by Medea to kill their father when trying to rejuvenate him. His first victory was in 442 with a play of unknown name. Two plays, however, have come down to us which seem to belong to an earlier date. The *Cyclops* is a satyr-play and the only complete specimen of its class, though we may now compare it with the papyrus fragments of Sophocles' *Ichneutae.* A satyr-play is neither tragedy nor comedy: it has the general tone, form and diction of tragedy, but the Chorus are satyrs and one of the characters must belong to the "comic" rather than the "tragic" tradition —*i.e.*, to the Kômos, or revel, rather than the Lament—like the Cyclops himself, or the drunken Heracles, or the thief Hermes. The *Cyclops* is a gay and fantastic piece, based on Homer's story of Odysseus' escape from the Cyclops' cave. Shelley's translation well catches the spirit of it.

The *Rhesus* has come down to us in a peculiar condition and is generally considered spurious. However it is known that Euripides did write a *Rhesus,* and tradition says he was "very young" at the time, which might account for the peculiarities of style in the extant play and particularly for its imitation of Aeschylus. It is a young man's play, full of war and adventure, spies in wolf-skins and white chargers and chivalry. On the other hand there are marks of lateness in the use of four actors and the free treatment of the Chorus; and something very like the later Euripides in the exquisite final scene, where the Muse weeps for her slain son. The *Rhesus* cannot possibly be a work of the late or middle period of Euripides; the style proves that. But it might be a youthful play, as tradition says, worked over by one or more later hands. The working-over indeed is certain from the fact that we know of three versions of the opening scene.

Alcestis.—In the year 438 appeared the romantic tetralogy *Cressae** (or *Women of Crete*), *Alcmaeon in Psophis**, *Telephus** and *Alcestis.* The *Alcestis,* still extant, took the place of a satyr-play as fourth in the tetralogy, and may be called pro-satyric in style and plot. Admetus has been granted the right, when his day of death comes, to escape if he can find a willing substitute. His old parents refuse to die for him; his young wife Alcestis consents and dies. Heracles passing the house on his travels is given hospitality, and is already revelling and crowned with flowers when he learns what has happened. He goes out into the night to wrestle with Death and rends his prey from him. We have here one "comic" character, the revelling Heracles, and a touch of the fantastic in the scenes between Thanatos and Apollo, Admetus and Pheres. The death of Alcestis is an obvious poetic theme, and most tenderly treated, but it is like Euripides to raise pointedly the question of Admetus' conduct in asking her to die. His self-satisfaction is broken down in a biting scene between him and the

*An asterisk denotes a lost play.

old father who had refused to die for him, but at least had not shifted his own fate on to another. As he returns to his empty house he cries: "At last I understand."

The other plays of this tetralogy also show the romantic style—*i.e.*, an admixture of adventure, variety and love interest with the strict theme of tragedy. The hero of the *Alcmaeon** is the son of that Eriphyle who had betrayed her husband to death for the sake of a magic necklace with a curse upon it. Alcmaeon kills his mother, seeks purification from the king of Psophis and is betrothed to his daughter Arsinoë, to whom he gives the necklace. But the whole earth is polluted by his mother's blood, and he wanders on till he comes to the alluvial islands at the mouth of the Achelous, which are untainted because they had not existed at the time of his sin. He settles there and marries Achelôus' daughter. She demands the necklace, and he returns to get it from Arsinoe, who discovers why he wants it, and has him murdered on his road back.

In the *Cressae** the princess Aërope secretly loved a young soldier; her angry father cannot bring himself to kill her, but gives her to a Greek sailor to throw into the sea. The sailor helps her to escape to Greece. The story itself is a common ballad motive and offends no one as long as it is not made too real. But it seems that Euripides did make it too real, and Aërope's songs of love were remembered against him even after his death. The *Telephus** was apparently seen by Aristophanes, then a boy of 16, and made an impression on him which he never forgot. Telephus, king of Mysia, had been wounded by Achilles and, when the wound would not close, was told by an oracle "the wounder shall heal." Consequently he goes disguised as a beggar to the enemy's country, to the heart of the Greek army and Agamemnon's palace. He is discovered; but snatches the baby Orestes from the cradle and threatens to dash him on the ground unless the Greeks will hear him. They consent; and he pleads the cause of himself and his country, and convinces them. The parodies in Aristophanes, *Acharnians* lay stress on the "gift of the gab" possessed by Telephus, on his hair-breadth escapes, and, curiously enough, on the rags and wallet of his beggar's disguise. It is hard to see how else he could have been dressed, if he was to be disguised at all, but apparently the treatment was a little more realistic, or less purely symbolical, than the audience of 438 B.C. expected. Later we find even Sophocles dressing the outcast Philoctetes in rags.

Medea.—Up to this time the chief notes of Euripides' work were variety, invention, romance and scenic effect; his analytic and destructive power of thought had hardly shown itself. The next play that we possess is the *Medea*. It appeared in 431 B.C. with the *Philoctetes**, *Dictys** and a satyr-play *The Reapers**. The *Medea* was placed by the judges at the bottom of the list, and thereafter took its place as one of the consummate masterpieces of Greek tragedy. It begins where the *Daughters of Pelias** ended. Jason has fled with Medea to Corinth, which is ruled by an old king, Creon, with a daughter but no son to succeed him. The famous Jason will exactly do as a son-in-law, if only he will discard the mad barbarian woman who is ruining him. Jason consents. Creon orders Medea to instant exile, but she obtains one day's grace . . . to make arrangements for her children. She uses it for her revenge. There is a wonderful scene with Jason, the man still held back by some conventional courtesy from telling the woman how he hates her, and offering to provide her generously with everything in the world except the one thing she needs, and she torturing him because he will not love her. Eventually she sees that the way to break him is to make him childless. She sends her two children to bear a gift to the new bride. It is a crown and robe, a gift from her divine ancestor, the Sun, which she has steeped in burning poison. The bride dies in agony together with her father who has tried to save her. Medea kills her two children behind the barred door of her house, against which the women of the Chorus beat in vain. Jason finds her laughing over the bodies. She loves her own pain since it means that he shall have happiness no more, and the daughter of the Sun sails away on her dragon chariot.

*An asterisk denotes a lost play.

The play is remarkable not merely for its concentrated passion, but for its daring and realistic psychology. The case for barbarian against Greek and for woman against man, with all its madness as well as its reason, is marvellously stated. More than one woman now in Broadmoor has killed her child for the same motive as Medea. The Aristotelian Dicaearchus says that Euripides based his play on the *Medea* of Neophron, a writer of unknown date. There would be nothing improbable in this. All heroic or legendary subjects were treated again and again. But the lines that are quoted from Neophron's *Medea* seem clearly to be modelled on Euripides, and not vice versa.

Hippolytus.—The *Hippolytus*, produced in 428 B.C., did win the first prize, besides establishing itself in permanent fame and inspiring Seneca and Racine to some of their finest work. The plot is a variant of a theme found in an ancient Egyptian "novel" and in the Pentateuch; the wife who falls in love with the chaste youth, and, when rejected, slanders him. Theseus—not here the ideal democratic king, but the stormy adventurer of the poets—had in his youth conquered the Amazons and ravished their virgin queen. She died leaving a son like herself, Hippolytus, who rejects the love of woman and lives in mystic communion with the virgin goddess, Artemis. Some 20 years later Theseus wedded Phaedra, daughter of Minos, and she by the evil will of Aphrodite against Hippolytus, fell in love with him. She concealed her love and was trying to starve herself to death, when her old nurse discovered the secret and told Hippolytus under an oath of secrecy. He contemptuously rejected her. Phaedra, in a rage of fear, writes a false accusation against Hippolytus and hangs herself; Hippolytus, charged by Theseus with the crime, will not break his oath, and goes out to exile and death under his father's curse.

The story is treated by Euripides with wonderful power and purity. The strife of superhuman forces in the background, Aphrodite speaking the prologue and Artemis bringing peace at the end, seems to make the human beings more sympathetic and their fate typical of an eternal conflict. The play, as we have it, is said to have been re-written. The first version seems to have told the story of the "novel" straightforwardly, with a shameless heroine who personally declares her love to Hippolytus, and, to judge from Seneca's imitation, with other strong theatrical effects. In the extant play Phaedra never speaks a word to Hippolytus. It looks as if we had here a rare phenomenon; a second treatment of a theme which, instead of keying everything higher and adding to the stage effects, deliberately aimed at restraint and *Sophrosyne*. To Comedy, however, any stick was good enough to beat Euripides with. We find repeated attacks on one phrase: spoken by Hippolytus: *ἡ γλῶσσ' ὀμώμοχ', ἡ δὲ φρὴν ἀνώμοτος* ("'Twas but my tongue, 'twas not my heart that swore"). The line is a passing flash of indignation at the trap in which he has been caught, and when the time comes he keeps his oath at the cost of his life. Yet it is cited as a wicked sophistry! The extant play has the second name of *Stephanêphoros*, "The Wreath-bearer," from the wreath which Hippolytus lays on the altar of Artemis; the first was called ὁ Καλυπτόμενος, "who veils himself," though as a matter of fact Hippolytus does that in our play also (l. 946).

Andromache.—The *Andromache* is said by the scholiast to have been produced "about the beginning of the Peloponnesian War," a date which would suit the style and metre. No "*Andromache* of Euripides" was recorded in the official Lists of Performances at Athens, and Callimachus found the play inscribed with the name of "Democrates," a person otherwise unknown. It would seem, therefore, that for some reason Euripides gave his play to another man to produce, as Aristophanes sometimes did. The situation is moving, and some scenes and lyrics effective; but the play, as a whole rather unsatisfactory. (The scholiast's phrase *τὸ δρᾶμα τῶν δευτέρων* is obscure.) Neoptolemus, son of Achilles, who had taken Andromache, the widow of Hector, as his concubine, has put her away on his marriage to Hermione, daughter of Helen, but still likes and trusts her. Hermione is childless and suspects Andromache of bewitching her. Her old betrothed, Orestes, still loves her; and her father, Menelaus—represented as a villain—is possibly in league with him. Neoptole-

mus being away at Delphi, Andromache and her child are about to be murdered by Menelaus, but are saved by the old Peleus. Menelaus retreats, leaving Hermione in despair, when Orestes, who has been waiting on the borders for this moment, suddenly appears and gets her to fly with him. "She need never fear Neoptolemus again!" The meaning of these words presently appears, when a Messenger comes from Delphi announcing the murder of Neoptolemus by Orestes and his men. Old Peleus, broken with grief, is comforted by the appearance of Thetis *ex machina,* one of the most beautiful of these divine epiphanies.

Hecuba.—Before Aristophanes' *Clouds* in 423, and perhaps after the purification of Delos in 426 (l. 455 ff.), came the *Hecuba.* The play shows the transformation of Hecuba, by the cruelties and treacheries of war, from a stately barbarian queen into a sort of devil. Her daughter Polyxena, the most beautiful of all Euripides' virgin martyrs, is sacrificed on Achilles' tomb to satisfy a superstitious mob. (It shows the beginning of a new note of bitterness in Euripides that the two Athenian heroes, the sons of Theseus, amid all these horrors, did what? They quarrelled, but both were for the murder!) Her other daughter, Cassandra, the virgin prophetess, has been taken for Agamemnon's slave. But the worst is that her youngest son, Polydorus, whom she had sent for safety away from the war to her guest-friend Polymestor, king of Thrace, has been murdered by the Thracian for his gold. Having persuaded Agamemnon to stand aside, Hecuba inveigles Polymestor and his two children into her room among her women: they kill the children and then blind the father, and the eyeless barbarian crawls back shrieking to Agamemnon for help. Legend told that Hecuba, maddened with suffering, was transformed into a sort of hell-hound with fiery eyes, whom sailors saw at night round the hill where she was stoned. The prophesies of the dying Thracian speak of this, and in the fury of the scene it seems credible, just as Medea's dragon-chariot does.

Two Patriotic Plays.—As against the bitterness of the *Hecuba* we may note two patriotic plays, the *Heraclidae,* dating early in the war and the *Suppliant Women,* about the Peace of Nicias (421 B.C.). In the *Heraclidae* the children of Heracles hunted by the tyrant Eurystheus, and led by Heracles' old companion, Iolaus, take refuge in Athens. The king, Demophon, son of Theseus, defies the overbearing Argive herald and undertakes to protect them. An oracle, however, has declared that a virgin of royal birth must die if they are to be saved. One of the daughters of Heracles, Macaria, overhears the discussion of this and offers herself. Iolaus says, "No: lots must be drawn," but she prevails on him. She is led out to die, and Iolaus, despairing and unarmed, takes down the sacred armour hanging in a temple, and prays to be made young for one day. The prayer is granted and the battle won. (The *Heraclidae* seems to have come down to us in a mutilated condition. It is very short: there is no account of Macaria's death, and some passages quoted from it by ancient writers are not found in our text.)

The *Suppliant Women* also opens with a scene of supplication. The mothers of the Seven Argive Chieftains slain before Thebes, led by Adrastus, have found Aethra, King Theseus' mother, at her prayers beside the altar of Eleusis, and have surrounded her with a chain of suppliant branches which she dares not break. They ask that Theseus shall recover for burial the bodies of their sons, whom the Thebans have flung out to dogs and birds. Theseus at first refuses. The Argives did wrong to make war; he will not risk war for their sake. At last: "Women in sorrow call thee, and men dead," says Aethra, and he yields.

Patriotic plays are generally too shallow and boastful to make good literature. But it is interesting to see what qualities the patriot boasts about. Euripides idealizes Athens as the helper of the oppressed, the champion of Hellenism and true piety; but also as the city of enlightenment. For when the putrefying bodies are recovered from the field, the old practice would have been, first, to treat them as polluted and let only slaves tend them, and next to lay them before their mothers so as to increase the weeping; Theseus tends them and "shows them love" himself, and he keeps the mothers away from the hideous sight. It is the Hellenism or humanity of Athens that Euripides loved, and her failure in that is the cause of his quarrel with her. It is strange to observe that he seems at this time to have favoured Alcibiades as a leader. A phrase about "a shepherd young and noble" in the *Suppliant Women* (l. 190) may be meant to suggest him: the play commends his pro-Argive policy, and the ode for his Olympian victory in 420 B.C., which Plutarch read, was said to be the work of Euripides.

Heracles.—The same note is struck in the later part of the *Heracles* (called in the Aldine edition Ἡρακλῆς Μαινόμενος, *Hercules Furens*). That play opens with a suppliant scene: in the absence of Heracles his wife and children are left in Thebes in the power of the tyrant Lycus ("Wolf"), who is determined to extirpate the whole race. They have fled to an altar, hoping to stay there till Heracles' return, but Lycus proceeds to burn them out. They get leave to perform the funeral rites for the children, and have done so—a terrible omen—when at last Heracles appears. He saves them; but the deliverer is strangely excited and boastful and unlike himself. The Elders of the Chorus see in a dream a vision of Madness descending upon him. It comes: he murders his wife and children, and then, finding what he has done, is about to kill himself, when Theseus arrives. He hides his face and warns Theseus to keep away and avoid the pollution; but in a moment his friend's arms are round him and the shrouding mantle drawn off. Theseus persuades him that the great Heracles, the saviour of Hellas, must not die, but fulfil in spite of suffering whatever further tasks life may have in store. The scene is remarkable both in its treatment of the problem of suicide and in showing again Euripides' conception of the "wisdom" of Athens, typified as usual by Theseus.

The *Heracles* is noteworthy in two other ways: for its plain and outspoken denial of current myths:

> Say not there be adulterers in heaven,
> Nor prisoner gods and gaoler. Long ago
> My heart hath known it false and will not alter.
> God, if he be God, lacketh naught: all these
> Are dead unhappy tales of minstrelsy.
> (*Her.* 1341 ff.; *cf. I. T.* 385 ff.)

(*ἀοιδῶν οἵδε δύστηνοι λόγοι*). And secondly for a wonderful lyric about youth and age, claiming that, while all else passes, poetry does not. The poet had now, it seems, reached the age of 60 and was a *Geron,* relieved of military service. "I care not to live if the Muses leave me; may their garlands be about me for ever! Even yet the age worn minstrel can turn Memory into song." *Ἔτι τοι γέρων ἀοιδὸς κελαδεῖ μναμοσύναν.* The prayer was granted, but granted at a heavy price. His poetry remained with him undimmed, but it was a cause of strife with the city he loved and a proclamation of his broken hopes. Thucydides and all our other authorities testify to the growing corruption of life wrought by the Peloponnesian War, and the increasing savagery of the democratic war-party.

Ion.—The *Ion* is sometimes described as a glorification of Apollo and of Athens. If so, why is Apollo the villain of the piece, why are the legends of Athens made barbaric, her shrines unclean and her legendary princess a polluted woman? Why does the hero explain that he would sooner be a slave at Delphi, where one is not jostled off the pavement by the scum of the earth, than a free man in Athens "a city full of terror," where good men dare not speak?

The princess Creusa, ravished by Apollo, had laid her babe in the cavern where she had met him. She came again and the child was gone. Later she married a foreigner, Xuthus. Having no children the pair went to Delphi to consult the god. There Creusa meets the foundling Ion—really her own son whom Apollo had saved—and the two are strangely attracted to one another. She intends to ask Apollo what he has done with her child, but in the meantime Xuthus has questioned the god and is made to believe that Ion is his own illegitimate son. He proposes inventing some lie to deceive his wife and adopting the boy. An old household slave, devoted to Creusa, tells her of this plot. Betrayed by god and man, she cries out her story against the Holy Place. She may be disgraced for ever, but at least she will drag down this devil who sits crowned with flowers and singing to the lyre, while the

woman he has ravished goes mad and his child is torn by wild beasts! In the horror-stricken silence which follows there is none to advise her but the old slave. He wrings from her the whole story, and then calls for revenge. "Burn down the god's temple!" She dare not. "Poison Xuthus!" No; he was good to her when she was so unhappy. "Kill the bastard!" Yes; she will do that. The attempt is made but fails; Ion is revealed as Creusa's own son and the general confusion more or less satisfactorily cleared up, not by Apollo, who dares not show his face, but by Hermes who comes on his behalf. The Ion is the most ironic of the extant plays, and perhaps the most blasphemous. Many heroes in Greek legend were born of the love of a god for a mortal woman and their stories could be beautiful in the hands of Aeschylus or Pindar; but they were generally treated by Euripides in anything but a sympathetic spirit: *e.g.,* in the *Auge**, *Melanippe**, *Danae**, *Alope**.

The year 416 was to bring to a head the discord between Euripides and his city. In that year occurred an event of very small military or political importance, to which nevertheless Thucydides devotes 26 closely written chapters: the unprovoked siege of the small neutral island of Melos followed by massacre and enslavement. The whole case is argued out in Thucydides; its utter wickedness clearly exposed, and cynically justified by the Athenians. The next chapter begins the Sicilian expedition and the ruin of Athens.

The Trojan Women.—Euripides, apparently stirred by the same indignation as Thucydides, produced in the following spring an extraordinary tragedy, the *Trojan Women.* It represents the capture of Troy, the proudest triumph of legendary Greece, seen through the eyes of those who knew most about it, the conquered women. We see first, in the darkness, the gods of Troy, re-inforced by the offended Athena, waiting their hour. The captured women creep out from their huts; the Greek herald comes to announce how the slaves are to be distributed and to take Cassandra, the mad priestess, to Agamemnon's bed. Hecuba and the other women are filled with horror, but Cassandra herself is happy, seeing everything through a mist of vision, including her own ghastly death and that of "her bridegroom." Meantime Andromache, made slave to Neoptolemus, is planning how to win favour with her masters so that her child Astyanax may be allowed eventually to return and re-build Troy, when the herald comes back. He must take the child. The Greeks have decreed its death. The scene is perhaps the most harrowing in Greek tragedy. A scene between Menelaus and Helen, whom he longs to kill, and yet dares not, shows the conqueror as miserable as the conquered, and more contemptible. The body of Astyanax is brought back and decked for burial by his grandmother, the dead child and the very old woman being all that is left of the great city. In the finale come scenes of almost mystical grandeur. Hecuba cries first to the gods, who care not at all. Then to the dead, who did at least care and love, but cannot help. With no hope, no illusion anywhere, Hecuba faces That-Which-Is, and finds somewhere in the very intensity of Troy's affliction a splendour that cannot die. She looks on the burning city and tries to hurl herself into the flames, but is held back. With a crash the great tower falls; the Greek trumpet sounds through the darkness calling the women to the ships; and they go forth to their slavery.

The two plays that were produced with this tremendous tragedy seem to have led up to it: *Alexandros**, showing the curse upon Troy that came through sparing the fire-brand, "the seed of wrath"; and *Palamedes**, showing the curse upon the Greeks, who believed the liar and slew the innocent.

Two Romantic Plays.—The *Troades* is sometimes spoken of as introducing a period of gloom or pessimism in Euripides, but this is an exaggeration. One result of the "bad years" of the Sicilian expedition was a turn towards fantasy and romance, of which the most famous example is Aristophanes' *Birds.* In 414–412 comes the *Iphigenia in Tauris,* a delightful play in which the tragedy lies largely in exile and homesickness and the romance in lyrics of the sea. Iphigenia, about to be sacrificed at Aulis, was saved by Artemis and carried off to be her priestess among the savage Tauri, who sacrifice strangers. After many years two Greek youths are found on the shore and brought to the Priestess to be consecrated for death. (They are really her brother Orestes with his friend Pylades, who have been sent by Apollo's command to bring to Athens the statue of the goddess.) Much moved, she questions the strangers about Greece, and tries vainly somehow to show pity for them. She can save the life of one, if he will bear a letter for her to Greece; Orestes in a beautiful scene constrains Pylades to go. But to whom is the letter to go? "To Orestes." So the truth is revealed, but the danger remains. Eventually a plot is made for the three to deceive the king, get the statue to sea, and fly together. They have practically escaped when the wind changes and drives them back. But Athena, *ex machina,* makes Thoas forgive them and institutes the ritual connected with Iphigenia at Brauron.

*An asterisk denotes a lost play.

The *Iphigenia* seems to have had such a success that, since there was no opportunity for a long "run," the poet used a similar plot again next year in the *Helena.* He follows the old story of Hesiod that it was not Helen herself who was taken to Troy, but only her *eidolon* or image. (Helen was the Spartan marriage-goddess; and the rape of an image of the marriage-goddess was a known ritual in places where the marriage ceremony consisted in a carrying-off of the bride, as in Sparta.) The real Helen, an innocent and devoted wife, has been all the time in Egypt. First there was a good king who kept her for her husband, then came a bad king who wanted her for himself. She takes refuge at an altar. Meantime Menelaus, having taken Troy and suffered shipwreck, comes to the Palace. He and Helen meet; there are explanations and mutual amazement; and eventually the two escape by a plot very similar to the plot in the *Iphigenia.* There are charming lyrics in the *Helena* and the plot is ingenious; but as a whole it is unsatisfactory. It looks as if Euripides had been groping, with inadequate resources, towards a style of fanciful and unreal play—something like *Twelfth Night* or *A Midsummer Night's Dream*—for which the form of Greek tragedy was not suited. It is hard where it should be tender, and strikes us as absurd when it is meant to be miraculous or astonishing.

Much more successful, apparently, was the *Andromeda**, a romantic story of the rescue of the heroine by Perseus, when she was exposed to be devoured by the sea-monster. The fragments have a rare charm, and Lucian has a pleasant story of a tragedy fever that fell on the folk of Abdera and set them walking as if in a dream muttering verses of the *Andromeda**, by that time 500 years old!

Electra.—About the same date, or slightly earlier, came a play of a very different sort, the *Electra,* dubbed by Schlegel "the meanest of Greek tragedies." It treats the same theme as Aeschylus' *Choephoroe* and Sophocles' *Electra,* but in a different spirit. It may be described as a study of a heroic bloodfeud from the point of view of a civilized man. The vengeance of Orestes and Electra upon their mother and her paramour had been treated by Aeschylus as a problem of clashing duties. His hero obeys the god's command, but the horror of it unseats his reason. Sophocles treats the story in a Homeric or "heroic" spirit, with no qualms of conscience and no madness. Euripides studies closely what sort of children they could have been who would so nurse their hatred for years and at last work out their mother's murder. His Electra is a mixture of heroism and broken nerves, a lonely woman eating her heart in ceaseless broodings of hate and love, both unsatisfied. Orestes is a youth bred among the false dreams of exile and now swept away by his sister's more passionate will; haunted also, as Orestes traditionally was, by the shadow of madness. The same psychological study is applied to Clytemnestra. Most remarkable is the scene after the mother-murder when the brother and sister reel out from the house "red-garmented and ghastly" and break into an agony of remorse. The play ends with an appearance of the heavenly horsemen, Castor and Polydeuces, who definitely pronounce the deed of vengeance to be evil, speak words of pity for mankind and go forth on their eternal duty, which is not to punish but to save.

*An asterisk denotes a lost play.

Phoenissae.—The *Phoenissae*, or *Women of Tyre* (?410 B.C.) is an experiment of a different kind. It is the longest Greek tragedy and covers the longest stretch of story. Some critics have described it as "a whole trilogy in one play"; others as "epic rather than dramatic." It is written in a large and heroic style; but, in the manner of this period, it shows a background of clashing hatreds, ambitions and revenges, against which we see standing out one man's self-sacrifice and a mother's and a sister's love.

Polynices is besieging Thebes. Eteocles is king: the blind Oedipus lives imprisoned in the vaults of the palace. Jocasta speaks the prologue. After a scene in which Antigone looks from the wall on the enemy host, as Helen did in the *Iliad*, a disguised man with drawn sword enters looking for Jocasta. It is Polynices, whom she has begged to come and be reconciled with his brother. The brothers meet, but part in increased anger, and the battle begins. Creon consults the prophet Teiresias, who says that Thebes will be saved if Menoiceus, Creon's son, dies. Creon desperately arranges for Menoiceus to escape; the boy feigns consent, but as soon as his father's back is turned, rushes up a tower of the city and throws himself into the dragon's den. A messenger comes to Jocasta with news of the battle. The Argives are repulsed. Her sons are safe, but—the truth is forced from him—just about to engage in single combat. The mother, with Antigone, makes her way out through the army to separate the brothers, but too late. They have already slain each other in a "meadow of wild lotus," where she too kills herself with one of the swords. Creon, who takes over the government, proclaims that the body of Polynices shall be left unburied, that the accursed Oedipus shall be cast out of the land, and that the princess Antigone shall marry his son Haemon. Antigone defies him, and goes out to exile with her blind father, away from the brutalities of men, to the untrodden mountain.

Orestes.—The *Orestes* (408 B.C.) is a strangely violent play. Orestes, a few days after his matricide, lies mad and sick, nursed by his sister. They are prisoners in the palace, and the Assembly of Argos is debating their fate. Meantime safety dawns on their despair. Menelaus, with Helen and an army of veterans, has arrived in the harbour. He will of course save his nephew! Unfortunately he is the next heir to the kingdom and he behaves ambiguously. The sick man blazes into rage and Menelaus becomes an open enemy. All is lost, when the faithful Pylades breaks into the palace to share his friend's fate. The decision of the assembly is announced: the prisoners must die. But at least they can strike first: kill Menelaus—or, better, kill Helen and then die. Better still, capture Hermione, and threaten to kill her unless the villain Menelaus will save them! The madness of Orestes infects the whole play. Helen escapes, being divine; but Hermione is captured. Menelaus rushes up only to find the gate barred and the madman on the roof shrieking derision and holding a sword at his daughter's throat. Menelaus rejects all terms. Orestes' party sets fire to the palace, Menelaus batters at the burning gate, when suddenly with a crash of thunder Apollo speaks and strikes all beholders into a trance. They awake from their trances with the fury gone out of them and the immediate past forgotten. Finding Hermione in his arms Orestes draws her to him, and thus it happens that, as all Greeks knew, she became his wife! Apollo tells them of their future lives and charges them to forgive one another. This violent epiphany of a god, changing at a word the whole course of action, is unique in our remains of tragedy (*cf.*, however, the *Iphigenia in Tauris*). The success or failure of the effect would probably depend on the audience and the stage-management.

Estrangement from Athens.—The *Orestes* was the last play which Euripides produced in Athens. We hear much of his increasing isolation. In 412 indeed he had been invited to write the national epitaph on the soldiers slain in Sicily; but that short-lived Government of "intellectuals" was soon swamped again by the war party. This was the time when, as Thucydides says, "men tried to surpass all records by the ingenuity of their plots and the enormity of their revenges." The old poet was doubtless considered half a traitor for being against the war party. He was anyhow a dangerous sophist; and we hear that he was prosecuted for impiety. He was not convicted, but other charges remained. He had written plays to deny the gods, to advocate perjury, to defend adulteresses and worse. What must his personal life be? No wonder he lived so secretly, he and his black-avised secretary Cephisophon. Perhaps he was a miser with secret wealth? An action was brought by one Hygiainon to make Euripides perform some liturgy instead of himself as being richer. The result is not known, but the line "My tongue has sworn" was brought up in court to show how little the defendant could be believed. There may have been some darker cloud (not the infidelity of his wife; *see* above). The *Life* tells us that "he lost patience with the ill-will of his fellow-citizens"; Philodemus says he left Athens "in grief, because almost all people were maliciously rejoicing over him." Whatever the cause, at the age of 76 he struck off into voluntary exile. He went first to Magnesia, probably the Magnesia near Ephesus, where he had already some connections, having been *proxenus*—a sort of consul—to Magnesians resident in Athens; soon however he went on to the court of Archelaus of Macedon, where he produced a tragedy, *Archelaus*, called after his host's legendary ancestor. The king was anxious to Hellenize his semi-barbarous court by collecting "wise men" from all parts of Greece, and must have heard the story how some of the Athenian prisoners in the quarries of Syracuse had been granted their freedom for teaching their captors choruses of Euripides.

There are several stories of the poet's adventures with these wild Macedonians, among whom a youth could not dine with grown men till he had killed a boar, nor put off a leathern girdle till he had killed a man; but if he had really been eaten by the king's hounds or caught in some sensational intrigue, Aristophanes would certainly have mentioned it in the *Frogs*. We only hear that he was dead before the Dionysia of 406, leaving behind him three plays *Iphigenia in Aulis, Alcmaeon in Corinth** and *Bacchae*. The first and third are still extant.

Last Plays.—The *Iphigenia in Aulis* presents many problems. It is incomplete in our mss., to which an unmetrical last scene was added at the time of the Renaissance. But it must also have been seriously incomplete at the time of the poet's death and been finished by another hand. The plot deals with the trapping of Iphigenia to Aulis to be sacrificed; the mental struggles of Agamemnon, the intrigues of Menelaus, the discovery of the plot by Clytemnestra, the bewilderment and indignation of Achilles and the acceptance of her doom by Iphigenia. She was probably rescued at the altar by Artemis, but the last scene is lost. The play shows a transition from the style of tragedy proper to that of the New Comedy. Its metre deviates from the tragic, permitting for example the elision of -αι; the messenger, instead of being formally announced, rushes in and begins his speech in the middle of a line; there are two different opening scenes inartistically combined (*cf.* the *Rhesus*), and great variety of incident, including one scene closely akin to Menandrian comedy—where Achilles thinks that Clytemnestra is making overtures to him. There is much psychology: the brothers Agamemnon and Menelaus quarrel and fiercely analyze one another's faults, but by the end each wishes to give way to the other. There are fine studies of Clytemnestra still young and innocent, of Achilles and above all of Iphigenia herself, at first utterly crushed, but, on reflection, exalted by the thought of dying for Hellas.

The *Iphigenia* is all invention, entertainment, psychology; it is full of informalities and interruptions: its Chorus is insignificant. Curiously different is the *Bacchae*. The *Bacchae* takes an old ritual story with fixed characters: God, Old King, Young King, Prophet, Mother. It is formal throughout and its Chorus is its very soul. In this extreme of formality and faithfulness to ancient tradition Euripides seems to have found his greatest originality and freedom.

The plot is little more than the regular sequence of scenes belonging to the cult of the Year Daemon: the Daemon and his Enemy, who is exactly like himself: the Contest, the *sparagmos* or Rending, the Messenger, the Lamentation mixed with Joy-cries, the Discovery of the scattered members, and the Epiphany

*An asterisk denotes a lost play.

of the God. The god Dionysus comes with his inspired Bacchanals to his own land of Thebes and is rejected by his kindred. He sends his divine madness upon them. The king, Pentheus, persecutes and imprisons the god and the holy women; then yielding in spite of himself to the divine power, agrees to go, disguised as a Maenad to watch the secret worship on Mt. Cithaeron. He is discovered and torn to fragments. His mother returns in triumph, dancing, with her son's head, which she takes for a lion's. It is too much. The Chorus of Maenads, hitherto wildly devoted to Dionysus, are transfixed with horror. Dionysus appears in glory pronouncing judgment on all who have rejected him. The mortals go forth to their dooms, still faithful, still loving one another, while the ghastly and triumphant god ascends to heaven.

The marvellous power of the *Bacchae* is beyond doubt. The spell of Dionysus affects the reader and makes the world seem mad. But the meaning of the play, for it certainly seems to have a meaning, is much disputed, and may perhaps be helped out by an analogy. Imagine a free-minded modern poet composing for some local anniversary a rhymed play in the style of the Mysteries on the legend of some mediaeval saint, persecuted by a wicked emperor, whom he threatens with hell-fire. Imagine the emperor brutal and despotic, the saint very saintly and the songs of the persecuted Christians very beautiful; and at the end the emperor writhing in hell-fire and the saint in glory saying "Hallelujah! What did I tell you?" Neither the exquisite beauty of the Bacchanal poetry nor the savage cruelty of the god can be denied. Both are true. After all, Euripides, with all his lucidity, never professes to be lucid about the ultimate mystery of the world. He sometimes denies, sometimes asserts, the rule of divine justice, or the existence of some "Great Understanding" and some life beyond the grave "dearer to man than this" (*Hipp.* 191 *ff.*). He is never apparently exercised by the problem whether God, or "the divine," is one or many, but, with all his passionate belief in "wisdom," he seems to have a strong sense of man's comparative unimportance in the presence of unknown powers: δουλεύομεν θεοῖς, ὅτι ποτ' εἰσὶν οἱ θεοί (*Or.* 418).

BIBLIOGRAPHY.—The Alexandrians possessed of Euripides 67 tragedies and 7 satyr-plays *plus* 3 tragedies and one satyr-play which were considered spurious. They believed him to have written altogether 92 plays, *i.e.*, 23 tetralogies; but it is not clear whether they took into account one or two plays, like the *Andromache* and the *Archelaus*, which were not recorded in the *didascaliae* (Wilamowitz, *Analecta Euripidea*, p. 145). Nauck's collection of the *Fragmenta* (2nd ed. 1889) gives 1,132 fragments, the last 26 being doubtful, from 55 lost plays. Papyri and other sources (esp. Johannes Logothetes, see *Rhein. Mus.* 63) have added passages from the *Antiope*, the two *Melanippae*, *Oeneus*, *Stheneboea*, *Phaethon* and above all the *Hypsipyle*. *See* Hunt, *Fragmenta Tragica Papyracea* (1910) and von Arnim, *Supplementum Euripideum* (1913).

The mss. of Euripides fall into two classes: one with scholia and one without. The former represents a collection of ten plays (*Hecuba, Orestes, Phoenissae, Medea, Hippolytus, Alcestis, Andromache, Troades, Rhesus* and originally *Bacchae*) selected for the use of the schools about the 4th century A.D., with a commentary compiled from earlier sources; the latter, comprising 18 or more plays, seems to represent some odd volumes of a complete edition of Euripides, with arguments, dramatis personae, and variant readings but no commentary. Its archetype was doubtless the edition by Aristophanes of Byzantium (*c.* 200 B.C.) of which we can form an adequate picture from the papyrus of the *Hypsipyle* (*Pap. Oxyrh.* 852). A further selection was made in Byzantine times of three plays, *Hecuba, Orestes, Phoenissae,* which occur in a vast number of mss.

The scholia-plays are all found in Vat. 909 (V.), *saec.* xiii., and some in the better mss. Marc. 471 (M) and Paris 2712, 2713 (A, B). The uncommented plays depend on Laurentianus xxxii. 2 , *saec.* xiv. (L or C), which contains all the plays except the *Troades*, and one on a ms. (P) of which half is in the Vatican (Pal. 287) and half (formerly called G) in the Medicean library (Laur. 172): this contains all the plays. There are many inferior Byzantine mss., while some 32 papyrus fragments and other ancient remains are useful in testing the soundness of the texts (Oldfathers *Greek Literary Texts*, Madison, Wis., 1923). Of similar value is the curious Byzantine tragedy, *Christus Patiens*, a cento attempting κατ' Εὐριπίδην τὸ κοσμοσωτήριον ἐξειπεῖν πάθος. It bears the name of Gregory of Nazianzus, but is attributed by Krumbacher to the 11th century. The scholia may be divided into those belonging to the 4th century edition (*Sch. Vetera*) and containing much knowledge from the best periods of Alexandrine and Roman scholarship, and those added afterwards (*Sch. Recentia*). There are great masses of late Byzantine scholia, especially on metres (editions by Dindorf, 4 vols., 1863; rather promiscuous; better selected and arranged by E. Schwartz, 2 vols., 1887, 1891).

Editiones principes: J. Lascaris (Florence, 1496), *Medea, Hippolytus, Alcestis, Andromache.* M. Musurus (Aldus, Venice, 1503), all the extant plays except *Electra*, which was first published by P. Victorius in 1545.

Of the older commentaries we may note especially: Valckenaer's *Phoenissae* (1755) and *Diatribe in Eur. perditorum dramatum relliquias* (1767); Markland, *Supplices* and *Iphigeniae* (1763–71); Porson, valuable for establishing metre and diction, *Hec., Or., Phoen., Med.* (1797–1801); Elmsley (similar) *Med., Bac., Hclid., Suppl.* (1813–21); Weil, *Sept Tragédies d'Euripide* (1879); Paley, the whole, oldfashioned but thoughtful (1872–80). In recent times may be mentioned the numerous commentaries of Wecklein; Bruhn, *Bacchae, Iph. in Tauris;* Sandys, *Bacchae,* with archaeological notes (4th ed. 1900) and above all Wilamowitz-Moellendorff, *Herakles* (1889, reprinted 1895, with epoch-making introduction), *Hippolytus* (1891), *Ion* (1926). Also J. U. Powell, *Phoenissae* (1911).

Among the numerous essays on Euripides may be mentioned A. W. Verrall, *Euripides the Rationalist* (1895), *Four Plays of Euripides* (1905), *The Bacchants of Euripides* (1910); G. Norwood, *The Riddle of the Bacchae* (1908); Gilbert Murray, *Euripides and His Age* (1914), and introduction to his translations. P. Décharme, *Eur. et l'esprit de son Théâtre* (1893); P. Masqueray, *Eur. et ses Idées* (1908); Nestle, *Euripides der Dichter der Gr. Erklärungzeit* (1901); Steiger, *Eur. Dichtung und Persönlichkeit* (1912). The article by Dieterich in Pauly-Wissowa's *Encyclopädie* is excellent. Invaluable for the poet's works as a whole is Welcker's *Griechischen Tragoedien mit Rücksicht auf den Epischen Cyclus geordnet* vol. ii. (1839); interesting, though uncritical; Hartung's *Eur. Restitutus* (1843).

Critical editions: Matthiae (1829); Kirchhoff, important (1855); Wecklein (1898–1901) from Prinz's collations; Gilbert Murray, with help from Wilamowitz and Verrall (1902–09).

Translations: In English verse by Way (the whole, 3 vols., 1894–98): Gilbert Murray (*Hippolytus, Bacchae, Trojan Women, Electra, Medea, Iphigenia in Tauris, Rhesus, Alcestis*). Verrall, *Ion.* In German *Hippolytus* and other plays by Wilamowitz.

Some interest attaches to Browning's "transcript" of the *Alcestis* in *Balaustion's Adventure*, and to Goethe's reconstruction of the lost *Phaethon* in his *Sämmtliche Werke*, vol. 33 (1840). (G. G. A. M.)

EUROCLYDON, a stormy wind blowing from the north-east or north-north-east in the eastern Mediterranean (Gr. εὖρος, east wind; κλύδων, wave). Where the Authorized Version of the Bible (Acts xxvii. 14) mentions *euroclydon*, the Revised Version, taking the reading εὐρακύλων, has *euraquilo*, or north-easter. The word is sometimes incorrectly used for the Bora (*q.v.*).

EUROPA (or EUROPE), in Greek mythology, according to Homer (*Iliad*, xiv. 321), the daughter of Phoenix or, in a later story, of Agenor, king of Phoenicia. The beauty of Europa fired the love of Zeus, who approached her in the form of a white bull and carried her away from Phoenicia to Crete, where she became the mother of Minos, Rhadamanthys and Sarpedon. She was worshipped under the name of Hellotis in Crete, where the festival Hellotia, at which her bones, wreathed in myrtle, were carried round, was held in her honour (Athenaeus xv. p. 678). She apparently is a personification of the continent of Europe.

See Apollodorus iii.; Ovid, *Metam.* ii. 833; Helbig in Roscher's *Lexikon;* Hild in Daremberg-Saglio.

EUROPE, the smallest of those principal divisions of the land-surface of the globe which are usually distinguished by the conventional name of continents.

INTRODUCTORY

Individuality of the Continent.—The earliest mention of Europe is in the Homeric *Hymn to Apollo*, but there Europe is not the name of a continent, but is opposed to the Peloponnesus and the islands of the Aegean. The distinction between Europe and Asia is found, however, in Aeschylus in the 5th century B.C., but there seems to be little doubt that this opposition was learnt by the Greeks from some Asiatic people. On Assyrian monuments the contrast between *asu* "(the land of) the rising sun," and *ereb* or *irib* "(the land of) darkness" or "the setting sun," is frequent, and these names were probably passed on by the Phoenicians to the Greeks, and gave rise to the names of Asia and Europe. Where the names originated the geographical distinction was clearly marked by the intervention of the sea, and this intervention marked equally clearly the distinction between Europe and Libya (Africa). The difficulty of fixing the boundary between Europe and Asia where there is land connection has always caused uncertainty in the application of the two names, but never obscured the necessity for recognizing the distinction. Even in

the 3rd century B.C. Europe was regarded by Eratosthenes as including all that was then known of northern Asia. But physical features and climate finally determined that what we know as Europe came to be occupied by more or less populous regions in intimate relation with one another, but separated on the east by sparsely peopled areas from the countries of Asia, and the boundary between the two continents has long been recognized as running somewhere through this area. Within the limits thus marked out on the east and on other sides by the sea, the climatic conditions are such that inhabitants are capable of and require a civilization of essentially the same type, based upon cultivation of grain. Those inhabitants have had a common history in a greater measure than those of any other continent, and hence, however divided among themselves, are more thoroughly conscious of their dissimilarities from, than of their consanguinity with, the peoples of the east and the south.

Officially the crest of the Caucasus and that of the Urals were formerly regarded in Russia as the boundaries between Europe and Asia on the south-east and east respectively, although in the Urals it is impossible to mark out any continuous crest, though they form a boundary to some extent in climate and vegetation (*v. inf.*).

Extent.—The following calculations in English square miles (round numbers) of the area of Europe, within different limits, were given in Behm and Wagner's *Bevölkerung der Erde*, No. viii. (Gotha, Justus Perthes, 1891), p. 53:—Europe within the narrowest physical limits (to the crest of the Urals and the Manych depression, and including the Sea of Azov, but excluding the Caspian steppe, Iceland, Novaya Zemlya, Spitsbergen and Bear island) 3,570,000 square miles. The same, with the addition of the Caspian steppe up to the Ural river and the Caspian sea, 3,687,750 square miles. The same, with the addition of the area between the Manych depression and the Caucasus, 3,790,500 square miles. The same, with the addition of territories east of the Ural mountains, the portion of the Caspian steppe east of the Ural river as far as the Emba, and the southern slopes of the Caucasus, 3,988,500 square miles. The same, with Iceland, Novaya Zemlya, Spitsbergen and Bear island, 4,093,000 square miles. In all these calculations the islands in the Sea of Marmora, the Canary islands, Madeira, and even the Azores, are excluded, but all the Greek islands of the Aegean sea and the islands of Thasos, Lemnos, Samothrace, Imbros, Hagiostrati or Bozbaba, and even Tenedos, are included.

The most northern point of the mainland area is Cape Nordkyn in Norway, 71° 6′ N.; its most southern, Cape Tarifa in Spain, in 36° 0′ N.; its most western, Cape da Roca in Portugal, 9° 27′ W.; and its most eastern, a spot near the north end of the Ural mountains, in 66° 20′ E. A line drawn from Cape St. Vicent in Portugal to the Ural mountains near Ekaterinburg has a length of 3,293 m., and finds its centre in the west of Russian Poland. From the mouth of the Kara to the mouth of the Ural river the direct distance is 1,600 m., but the boundary line has a length of 2,400 miles.

Distribution of Land and Water.—Europe is unique among the continents in that no other is so deeply penetrated by the sea; the result is that it is composed of two compound peninsulas on the west flank of the Russian plain. The present relations of sea and land have obtained, with minor but important variations, during the historic period. Aquileia and Ravenna have been separated from the sea by a process of silting and the Rhone delta has grown (*see* R. D. Oldham, *Geog. Journ.*, London, lxv., 1925, p. 403); the North sea coasts have been attacked by the sea in several places but locally land has been added here and there; the opinion has been strongly held that land is rising out of the sea (or the sea level sinking) in Scandinavia; local tradition emphasizes attacks of the sea in the Gulf of Avranches, and there have been many changes in the volcanic zones of the Mediterranean. Earthquakes are reported for all Europe save the very stable Russian plain; there is thus no indication of finality in the form of Europe and it has certainly altered considerably since the beginning of the human period. The opinion is held by many that the land stood higher during the maximal ice-phases of the Pleistocene glaciation, and, however this may be, there is abundant evidence of the fact that the last conspicuous movement has been at the expense of the land, and archaeological hints suggest that such movements may have been important in western Europe towards the end of the 3rd millennium B.C. as well as earlier. It is thus a feature of Europe that detached fragments of one-time continental land now form islands in great profusion along its coasts and in its penetrating seas, and these islands have played a great part in the early development of maritime commerce and of the general development of civilization. The coasts of south Spain, Italy and North Africa lie parallel to the great curves of fold mountains and are not rich in islands save near the volcanic zone of south Italy. Though the east coast of the Adriatic is in the main parallel to the line of mountains, yet that line is really a group of lines which bend successively westwards from the general north-westward direction with the result that the broken and partly sunken ends form numerous islands set obliquely or sub-parallel to the coast. The northern Aegean has islands which may be mainly unsubmerged remnants of a sunken old block, but many islands of this area are in chains that show them to be emergent hilltops of a partially drowned mountain line. Sicily, Corsica and Sardinia and the Balearic isles belong to the systems of fold mountains and old blocks of the western Mediterranean basin, Sicily being largely fold mountain and volcanic material, the Balearics also a part of one of the fold mountain-arcs, and Sardinia and most of Corsica surviving fragments of a Hercynian block.

Whereas, in the Mediterranean, coast and mountain-fold are often, but not always parallel, this occurs but rarely in any direct way in Atlantic Europe, in which Hercynian and other blocks variously broken project into the sea and give a coast that usually cuts across the grain of the land and is characterized by large numbers of drowned valleys in Spanish Galicia, Brittany, western Britain and Ireland and Norway, the northern ones being heavily modified by ice-action. Whereas the St. George's and English Channels seem to be essentially drowned valleys, it is possible to describe the North sea as having coasts along which the European plain shelves down gently under water, and much the same can be said of the Baltic, large areas of which are very shallow indeed. The islands of Denmark and the Estonian coast as well as the Aland islands are merely unsubmerged fragments as on a larger scale are the British Isles, the Orkneys and Shetlands. As the coasts of Norway and Scotland are in part at least fracture-lines of an ancient land block, though the original directives (N.E.-S.W.) are the main ones still, these coasts are fringed with islands parallel or sub-parallel to the coasts, usually leaving channels along the coasts inside the islands (Vest Fjord, the Minch) that played a great part in the early centuries of navigation. The Black sea has a shelving north shore but its south shore is parallel to high structural lines and characteristically drops into deep water. This relation of deep water near coasts flanked by high structural lines is illustrated in the west Mediterranean and, to a certain extent, off the north coast of Spain as well as off the Norwegian coast, but not in the Adriatic, the shallowness of which contrasts markedly with the great depths of the Mediterranean basins. The White sea, Gulf of Finland and Gulf of Bothnia all have shelving shores and shallow water and represent portions of the European plain now covered by sea, the sea having within the human period also covered south central Sweden as well as a zone between the Gulf of Finland and the White Sea at times. These relations are important for the understanding of the distribution of European lakes (*v. inf.*).

PHYSICAL FEATURES

Mountains.—The most outstanding physical feature of Europe is the series of great mountain ranges of the Alpine system of Suess (*see* section on Geology), characterized by curved lines of heights in the Balkan peninsula, the Carpathians, the Alps and Apennines, the Atlas of North Africa and the Sierra Nevada, with the Pyrenees as a related range. To the south-west these mountain ranges enclose such basins as the shallow one of the Adriatic and the deep one of the western Mediterranean, to the south-east the sunken area of the Aegean, all with volcanic and earthquake zones of disastrous importance. Within the mountain

curves are rich lowlands such as those of Rumanian Wallachia, Hungary and the Po Basin. To the north and north-west of the Alpine system stand the remnants of the Hercynian and earlier chains (*see* section on Geology), mostly showing forms completely planed down and then uplifted afresh as blocks to be dissected afresh by wind, water and ice. The Spanish plateau, the central plateau of France, the Vosges and Black Forest, the Ardennes and Eifel, the hills of central Germany, Bohemia and much of its hill frame all illustrate the condition just described and some like the central plateau of France show striking irregularity of surface resulting from volcanic activities affecting these regions and probably related to the uprise of the Alps. This zone of old, round shouldered mountains stands out from the European plain which lies mainly to its north; the chief part of this plain may be said to stretch from south and east England, with the North sea covering a part of it, past the war-tried gate of Ypres in the gap west of the Ardennes, to Germany and Poland where it widens out into the vast Russian lowland. The Paris Basin (*see* FRANCE) is a portion outlying southwards.

North-westwards beyond the European plain as just defined we have mainly along south-west–north-east lines in Ireland, Scotland and Scandinavia, the old mountain masses of the Caledonian system of Suess (*see* section on Geology), with features showing that they were worn-down to a dead level and re-uplifted perhaps more than once; this topography is at any rate highly complex and owes some of its most striking features, such as the sharp coasts of Norway and west Scotland and Ireland, to the process of formation of the Norway sea and northernmost Atlantic mentioned in the Geological section. There is much evidence of vulcanicity in connection with the changes involved, and volcanoes are still active in Iceland at the end of the long ridge, now largely submerged, which extends north-westward by way of the Faröe islands. The Scandinavian highland is by far the largest highland structural unit in Europe unless the whole Balkan peninsula be counted as a unit. These broad topographical facts are complicated by influences of the Ice age which modified the valleys of Norway, west Scotland and Wales into their present steep-sided forms and, while exercising similar influences farther to the south-east, affected the Swedish side of the Scandinavian and the European plain to the east and south largely by deposition of immense moraines. These form lines of hills along the Prussian plain (*see* GERMANY and BERLIN) and are major topographical features in Denmark, central Sweden and south Sweden and Finland. Moraines also occur around the Alpine chains, but in a region of such striking topography they play a lesser part.

The Alpine system, broadly, forms in the west a dividing line between the region of marine basins with coastal hills and islands on the south and the broken hills and wide plains of the north. The former region, in which maritime intercourse and exchange began early, developed cities as a feature of its civilization long before the lands to the north. But the disposition of the Alpine system allows the oceanic westerly winds to penetrate far eastwards in summer however completely the dense cold air on the Russian plain may keep them out in winter. Thus oak, maples, elms, ashes, etc., are able to grow as far east as the Urals though hardly beyond. This climatic relation has permitted the gradual acclimatization of cereal cultivation and village-life and eventually the rise of trade and cities in northern Europe. The southern border of the Alpine system, apart from this line in the broken area of the Aegean, may thus be said to divide the civilization of Europe into two parts one in which cities are of immense antiquity, the other in which agricultural villages are a fundamental human characteristic, and no city existed until more than 2,000 years after Knossos in the south had become a metropolis.

Rivers.—The penetration of the seas into the land, the broken topography, and the openness of the land to oceanic influences give Europe a multiplicity of rivers of the most varied types. The Danube and Po are rivers of basins within mountain-fold curves, and their alluvial basins and multitude of tributaries are characteristic features. The rivers of the Mediterranean basin are often short, with torrent-sections followed by courses across flood-plains that have in many cases become malarious; many in the east cease to flow in dry summers. The Guadalquivir, Garonne, lower Rhone and in a measure the Ebro occupy troughs between fold ranges and Hercynian blocks (*see* section on Geology) and the mainstream is typically beneath the edge of the Hercynian block. The Guadiana, Tagus and Douro utilize weak lines in the Spanish plateau, called the Meseta, and the two latter have deep cut sections through the plateau edge on the way down to the Portuguese coast. The Rhine system depends on weak lines in the Alpine systems in its upper parts, on the syncline between the Alps and their Jurassic foreland, on fractures in Hercynian blocks and so on; the relations and characters of its regions and their feeders are thus most complex. This has contributed not a little, on the one hand, to make the Rhine a line of communication, on the other to make the problem of useful political boundaries in this region almost a hopeless one. Though the upper parts of Weser and Elbe are related to weak lines in the Hercynian blocks, their lower courses, and the Oder and Vistula are essentially rivers of the European plain with their courses and those of their tributaries affected by the west-to-east morainic lines mentioned above. Between these morainic lines are courses marked out for these rivers and their feeders and as these lines run for long distances, they have lent themselves to the construction of canal systems, almost without locks, which for example, played an important part in the rise of modern Germany. The Loire and Seine in France and the Thames in England drain basins that are essentially part of the European plain, modified by slight influences of the Alpine uplifts that have given hill frames around and thus have helped them to become distinct political units, which nevertheless have easy communications beyond their borders.

The rivers of the Russian plain are characteristically large with sluggish currents along great stretches though, as in the case of the Dnieper, there may be a more confined and rapid section where a low rocky barrier is cut through. Whereas apart from the Danube, which owes its special length (1,644 m.) to the fact that it drains a succession of basins, the rivers of western Europe are all less than 600 m. in length, save the Rhine (709 m.), Elbe (612 m.) and Vistula (estimates vary between 596 and 646 m.), there are on the Russian plain three rivers Volga, 1,977 or 2,107 m.; Ural 1,446 or 1,477 m.; Dnieper (estimates vary between 1,064 and 1,328 m.) well over 1,000 m. in length and the Kama, Don and Petchora near or above this limit with the Oka, Dniester and Viatka of the same length as the Rhine and Vistula. Flooding from melting snows in spring, and the long hard frosts of winter impart further peculiarities to these Russian rivers in their relations with man. The drainage system of Russia is however distinguished from that of Finland by the fact that though moraines affect their courses, yet, broadly, it may be said that the drainage system has re-established itself in Russia subsequent to the Ice age, while in Finland this is not the case and the country is an inextricable tangle of lakes behind moraines. In Scandinavia on the Norwegian side the slopes are so steep and coastal sinking has had such marked influence that the rivers are generally torrents falling into fjords which are submerged heavily-glaciated valleys; on the Swedish side the drainage from the highland runs mainly in direct (consequent) lines and glaciation has both scarped the valley sides and left moraines with the result that there are many parallel rivers and the upper courses of several are in the form of long lakes. There are many analogous lakes in Scotland.

Lakes.—Some points concerning lakes have just been made. An important fact is that every European lake with an area of more than 300 sq.m. (as usually calculated there are at least 17), belongs either to the Finland-Lapland region where moraines still dominate the topography or to structural low zones across from the White sea to the Baltic and across south central Sweden. These low zones have been under the sea in comparatively recent geological periods and their great lakes include Ladoga (7,004 sq.m.), Onega (3,765 sq.m.), Peipus (1,357 sq.m.), all in Russia and on its borders, and Vener (2,149 sq.m.), Vetter (733 sq.m.) and Malar (449 sq.m.) in Sweden. The largest of the Finnish system of lakes are Saima (680 sq.m.) and Pajane (608 sq.m.). The Swedish lowland-lakes, being between the Cattegat and the Baltic, have encouraged the development of water communications

across Sweden, and the journey from Göteborg to Stockholm across Sweden by boat is scenically one of the most remarkable on inland waters.

The lakes of the Alps and their foreland are of various types; some like those of north Italy are largely due to morainic dams across valleys formerly heavily glaciated; others have this origin in part but may occupy structural troughs as well. The largest lake of Europe apart from the northern region above discussed is however Lake Balaton (266 sq.m.) elongated parallel to and beneath the slopes of the Bakony Wald. Finland is unique in Europe in the matter of its lake system but regions of indeterminate drainage with abundant lakes and lakelets on a waterproof boulder clay cover occur in East Prussia, in Zealand (Denmark), in the Dombes region north-east of Lyons (France), and on a small scale in north Shropshire (England). The volcanic lakes of parts of the Apennines should be mentioned as also the tiny but characteristic corrie-lakes just beneath the ridges of the once heavily glaciated old mountain masses of Britain, with analogues in the Alps.

Marshes.—These are a feature of the geography of Europe especially on the Russian plain. From Leningrad eastwards to Vologda and the upper parts of the northern Dvina there stretch great areas of marsh more or less along the northern limit of the deciduous forest, and the marshes extend over large areas from Leningrad towards Moscow. The Peipus region on the Estonian-Latvian borders of Russia also abounds in marsh related to the distribution of boulder clay while farther south are the Pripet marshes. Here the Vistula-Dnieper low-zone north-east of the Carpathians crosses the European plain, and the Pripet marshes are the north-west part of the Dnieper basin towards the indefinite boundary between the drainage systems of the Black sea and the Baltic. These great areas of marsh have had great influence in isolating central Russia, especially from the west, and they determine to a large extent the historic ways of communication from the west into Russia, that of Vilna-Smolensk north of, and that of Lemberg-Kiev south of the Pripet marshes. The varied and broken topography of Europe farther west has prevented the occurrence of any marsh areas at all comparable with these but small patches occur in low alluvial basins and behind dunes on low shores and so on. The interior of Ireland is impoverished by large areas of bog land. There are great marshy areas in the European Arctic regions, in north Finland, the Kola peninsula and north Russia, nearly continuous eastwards beyond the northern Urals with the immense marshy lowland of the lower Ob.

CLIMATIC CONTRASTS

Europe is situated in the north temperate, and to a slight extent towards the north, in the arctic zone between lat. 35° N. (Crete) and lat. 71° N. (Norway), with islands of the Arctic ocean beyond this limit. It faces the North Atlantic ocean on the west and may receive from it at any time cyclonic disturbances which typically move eastwards especially along the belt between lats. 50° and 65° N. The prevalent wind is from the south-west and west-southwest, and the next most prevalent winds in western Europe are those blowing approximately from the south in the early phases of cyclones before those from the south-west set in; and those blowing from the north-west in the late phases of cyclones. The prevalence of the west-southwest winds brings a drift of water on the ocean surface moving with a northward component towards the coast, the Atlantic water is thus always relatively warm for its latitude and especially so during winter. The air over relatively warm water tends to be moist and at low pressure and the cyclonic systems of the north temperate zone are essentially systems of winds blowing in a counter clockwise curve into a low pressure centre. The warmth of the North Atlantic is so marked in winter that the cyclonic systems are very strong and the winds blow with a great fury, but another result is that the warming effect is carried far northward along the coast and even harbours along the north coast, like Alexandrovsk, can thus be kept open in winter. This mildness in winter, and in summer (for the neighbourhood of the ocean keeps summer temperatures down, and the moisture in the air promotes cloudiness), is of the utmost importance to man. He is able to maintain a good level of activity of body and mind and of intercommunication even in mid-winter provided that he is able to keep his standard of living high enough to ward off some of the ill-consequences of the small amount of sunshine.

The Russian plain in the matter of winter climate is, however, essentially an extension of the immense high-pressure system of north-central Asia and the cold dense air lying on it repulses sea-winds and cyclones, and causes long periods of steady intensity of cold which contrast strikingly with the variability of the west, that so often has mild temperatures with south-westerlies followed by a bracing day with north-westerlies. The steady severity of climate on the Russian plain, with fierce winds especially in the north, is not only a famous subject of folk tale and literature but also a crucial difficulty in the way of any scheme of government by consent, as it is difficult to maintain a good level of activity and vigilance under these conditions save among those fortunate enough to be able to create a more genial environment artificially. The social contrasts thus accentuated by climate have created bitter problems.

The Alpine system of mountains, instead of fronting the ocean as does the American Cordillera, is pointed westwards to the sea and the Russian zone of high pressure air in winter often spreads westward in a tongue along the highlands and may be continuous right across it to the highland of Spain, and may even thence reach the belt of oceanic high pressure which in winter lies over the mid-Atlantic about lat. 30°. The presence of this south-west to north-east zone of high pressure marks out a path for the Atlantic cyclones to the north of its habitual border. The severity of conditions gives six to eight months frost in a normal year on either side of the White sea, not diminishing below five months until one gets near a line from Leningrad to Moscow, and keeping above four months nearly as far south as Kiev, with the lower total of one to three months on the plain north of the Black sea. Approach to the sea westwards along the European plain is accompanied by reduction of the frost period from four months near the Baltic Dvina to three months near the lower Vistula, two months near Oder and one month along a line that approximately divides Danish Jutland (colder) from German Schleswig-Holstein (milder) and then runs southward from the neighbourhood of Kiel across the Weser to the Black Forest, *i.e.*, just east of the Rhine. To the west of this the cold is not only less but also much less continuous.

In summer the European parts, and especially the centre and south, of the Russian plain warm up so that regions which were at 20° F (average) in January, may be at 70° or more (average) in July. The expansion of air on the plain in summer promotes indraught from the sea, and the weak summer cyclones and westerly winds thus penetrate far in, and make the European plain and central Russia a region of summer-maximum in the matter of rain. As a result a broad wedge, with base from Uleaborg in Finland to the Bukovina and apex between Nizhniy Novgorod and Kazan, has more than 20 in. of rain per annum while the land north, east and south of this wedge has less, often much less. The broken topography in west Europe implies not only increase of total rainfall as compared with Russia but also variation of rainfall from place to place within relatively short distances. The total generally exceeds 60 in. per annum on several coastal patches from north Portugal via Ireland to South Norway. The summer rainfall of the Russian plain has its maximum in June in the south before the heating of the land has gone too far, in July in the centre, and in August north of the Gulf of Finland. Analogous relations hold good in east central Europe where the Danube basin generally has a June maximum, the north German plain and the east side of the Rhine basin a July maximum and the Baltic region except Denmark an August maximum.

These facts bring out the great contrast over against Atlantic Europe with its typical October maximum of rainfall and its December to January maximum in such regions as west Ireland and Iceland. The Netherlands are sufficiently influenced by the European plain to have their rainfall maximum in summer and like the Baltic lands they usually have it in August. Statements

concerning western Europe are however specially subject to reserve due to variability of seasons. Of recent years research upon the extent and date of melting of Arctic ice, especially in the north-west of the Atlantic area, has led to attempts to forecast seasons in a broad way and it seems clear that the contrast between the colder air over an ice-sheet and the warmer air over open water in winter is an important factor of air movements helping to settle the tracks of cyclonic storms and thus exercising great influence upon our seasons. The North Atlantic wedge of relative winter warmth, pointing north-eastwards and forming the main zone of cyclones, may thus be said to be bounded on the north by the influence of Arctic ice and on the south-east by the tongue of high-pressure reaching out from the Russian plain along the highland zone, often to the Spanish plateau and the subtropical high-pressure belt of the Atlantic. This wedge of relative warmth is in large measure the European region of agricultural-village civilization already mentioned, and it seems reasonable to say that the village in the apical part of that wedge has spread eastwards, *i.e.*, that the idea of the village has on the whole spread eastwards into the summer-rain wedge, the area of deciduous forest, in Russia, more probably via Kief than via Vilna (*see* above, *Marshes*). Nevertheless the wedge area has not had this type of penetration from base to apex; the agriculture of Europe owes a great debt to factors that have reached it via Asia Minor, south east Europe and the zone of European tongue of highland that is weak because of the basins of the Danube river that succeed one another in it; it was not only in the days of Islam that this zone brought disturbing influences into Europe's life. Before leaving the wedge area it is well to draw attention to the fact that a strengthening of the continental winter high-pressure conditions (such as would occur if the land lay higher) might well abolish this wedge which then, with its highlands and broken topography, would experience very severe conditions. The relation of these considerations to the glacial period is a matter that needs to be worked out still more critically.

The southern boundary of the wedge area is the tongue of winter high pressure that has been said to stretch, frequently, right out along the highlands from Russia to Spain and the Atlantic. That high pressure tongue generally separates off from the Atlantic influences the basin areas of the Mediterranean, though they may occasionally break through, either in South France with its deep tell-tale wedge of heavy rainfall having its base on the gulf of Gascony and its mistral wind blowing across the central plateau and down across Languedoc and the Rhone delta to the sea, or in the Adriatic farther east. In the Mediterranean region the relations of sea and land affect climate all the more deeply because of the strength of the mountain framework around the deep basins of the sea. High pressure on the highlands and low pressure over the sea, which long preserves much of the summer warmth appropriate to such latitudes, is a governing factor from October to March; and the cyclonic storms for which the Mediterranean is famous as well as winds down the mountains, *e.g.*, the bora, mistral and others, are natural consequences. In the western basin the contrasts develop most quickly in the north, giving a season of maximum rainfall in autumn as contrasted with a winter maximum along the coast of Algeria and Tunis. The configuration of south Italy facing the west Mediterranean basin gives it considerable rainfall in both autumn and early winter while the configuration of Sardinia gives it almost continental conditions in winter. Late-winter conditions with their diminution of differences of temperature between land and sea bring diminution of rainfall, and, then the seasonal increase of warmth in the lowlands before the Alpine snows have melted brings increased rain to the Alps in April and leads to the spread over the Alps of the low pressure areas that still tend to linger on the Mediterranean sea. The warming of the Sahara and North Africa changes these relations as summer advances and the sea is now cooler than the land and so is a high-pressure area. The set of the winds becomes southwards towards the deserts of North Africa, and probably the pull exercised by trade winds farther south is also felt; from June to September temperatures run high and rainfall is very low, the bay enclosed by south Italy and north Sicily being a little less dry even at this season thanks to its mountain frame facing the sea. The isotherm of 70° typically has the Mediterranean on its warmer side from early June to late September, and in July the averages in the western basin are as high as 75° to 78°. The general conditions just sketched need adjustment in detail for understanding of any particular region. Thus, the subtropical high pressure area over the Atlantic is markedly extended in summer and may spread into the Iberian peninsula but the mid-summer sun strongly heats the great plateau of that peninsula balanced about lat. 40° N. and correspondingly reduces atmospheric pressure which thus tends to be lower than would otherwise be the case.

The Adriatic region illustrates some of the conditions of the western Mediterranean in accentuated fashion, with its massive Dalmatian highlands closely fronting the sea. The rainfall along this highland edge is said to be the heaviest in Europe, it has an autumn maximum but its more southerly portions go on getting heavy rain well into the winter and April increase of rain is marked here as in the Alps. July and August are relatively dry. Summer temperatures are like those of the western basin but winter temperatures run lower. In the eastern Mediterranean, the Aegean, enclosed as it is by land, and subject to influences from the south Russian steppe, feels the cold still more than the Adriatic, and parts of it are a rain-shadow area of the Illyrian mountains. The early establishment of high-pressure conditions on the Russian plain in autumn (October) affects the Aegean region, which hence lacks heavy rainfall till contrasts between land and sea are thoroughly established in November, December and January. The summer is naturally very dry but the considerable early summer (June) rainfall of the Balkan land mass must not be overlooked. Summer conditions here include the southward set of the winds towards the heat of Africa and the Red sea, as already mentioned for the western Mediterranean, but here there seems to be a pull towards the great monsoonal air stream setting at this season on to India. The north or Etesian wind of the Aegean is famous in literature and history, rising with the day and calming towards night. Its regularity and the general predicability of the weather and the bright summer starlight were important factors, alongside of the multiplicity of sheltering islands, in the rise of navigation and maritime commerce in this their earliest home in the Mediterranean region.

Southern Asia Minor, the majority of the Aegean islands, Greece, Sicily, Corsica and Sardinia, south-east Spain and the North African coast have an average temperature above 68° F for four months and this period of heat is longer on the south-east side of the sea, where summer rainlessness is still more marked. The difficulties of summer heat affecting the health and well being of the general population and its participation in modern efforts towards government by discussion and consent should not be overlooked, nor their bearing on the social structure of classical Greece, for example, ignored. The more moderate climate of Italy and its greater rainfall are important facts. The Po Basin needs a short note. Its enclosure with a mountain frame makes the middle of the valley cold in winter, sometimes with temperature inversion (*i.e.*, the coldest air immediately above the surface of the land) and on the other hand the heat of summer in such a basin gives low pressure and a certain amount of rainfall. The special conditions in the Iberian peninsula with its spring rainfall in the northern half will be dealt with in the article on SPAIN.

THE STUDY OF SOILS

The study of soils is advancing quickly at the present time (1928), largely under the leadership of Russian men of science, of whom Glinka is one of the best known (*see* K. D. Glinka, *The Great Soil Groups of the World and their Development*, 1928). E. Ramann is contributing to this study (*Evolution and Classification of Soils*, 1928) and is also applying the views developed to the study of geographical distribution. It appears now that the direct influence of the composition of the underlying rock or deposit is by no means a determinant, and that climatic influences play the larger part, though their influence will work out differently

according as the rock or deposit is permeable or impermeable. Moreover the influence of the underlying material is far greater in a temperate climate than in a climate of extremes. As the newer classifications have been applied thus far in most detail in Russia the subject will be treated more particularly in the article RUSSIA, and this section of the article on Europe will be confined to an introductory statement.

Classification into transported soils such as loess, dunes, etc. (Aeolian formation), morainic, fluvioglacial, etc. (glacial formation), alluvial (fluvial formation), and sedentary soils has its utility but is applicable mainly locally rather than broadly over great regions and it is noted that the black earth appears over many different formations in eastern Europe, over loess, boulder clay, calcareous rock, etc. Temperature in its relation especially to rainfall and evaporation is one of the most important factors governing soil character. Surveying the soils of Europe broadly and using the new names as far as possible we have, according to Ramann the following classification:

(1) In the cold zone there are humid soils, because evaporation is slight, chemical weathering is slow and the soil may be water-logged in the open season and may thus be inclined to move or flow. Soils then are often tessellated by formation of great frost-crack patterns, and fine sandy material leaches out into the cracks. Many areas of the Tundra or Arctic zones are covered by hillocks said to arise from differential strains in freezing of the upper layers when the depth also is frozen but zones in between are not. Hillocks are also due to the form of moss-cushions which grow in the Arctic. On the heights rock splinters abound in the soils, which usually have the iron leached out of them by water and so are grey. In many places the depths of the soil may be permanently frozen though the surface may grow trees or even occasionally crops.

(2) In the temperate zone the soils are affected by the presence or absence of lime in the rock for, if lime is present, there will not be accumulation of acids from humus. The rock naturally affects the texture of the soil. In the north leaching by water which does not evaporate too quickly gives grey soils, generally poor in iron hydroxide but in sandy soils the iron hydroxide may not be got out of its combinations in the soil material and what little is got out is quickly carried away. Therefore grey soils are typical even fairly far south near sandy areas. Grey soils heavily leached are characteristic of north Scandinavia. Such soils in Russia are called *Podsol* and the humus here washes down into the subsoil and gives it higher iron-content, tending to form "a pan." Podsol is especially the soil of the northern coniferous forests of Europe but it occurs on mountains farther west. In the parts of Russia farther south, largely under deciduous forest, the bleaching is found again but the evaporation in summer is greater and "pan" is not generally formed; these soils are the *Forest Grey Earths*. The *Humid Brown Earths* develop where rainfall, temperature and evaporation are moderate and leaching is not taken to extremes. In dry summers lime in solution rises in the soil, humus content is low because organic matter decays quickly with moisture and moderate warmth, iron is present in fair quantity from decomposition of the soil material, but that quantity is much less if the underlying rock is poor in iron. The brown earths are coherent and do not powder easily; they need to be fed with organic matter if crops are to be grown year after year. They are the typical soils of the lowlands of central and western Europe and the surface does not differ much from the deeper layers, while the subsoil often contains fragments of the underlying rock. If the underlying rock be calcareous it dissolves away, and in extreme cases little soil is formed; but sometimes, as in central Europe where the summer is warm and dry, humus accumulates in some quantity and one gets a dark earth (reef soil) as for example on the Swabian Jura. The calcareous soils being dry through soaking away of the water become warm and evaporation is great. Moreover the humus acids combine with the lime and this prevents much accumulation of the humus acids in colloid form. The percolating water makes the surface poor in iron but the deeper layers may have more of it.

With more extreme climate as towards the south of central Russia the typical soil is black earth, rich in humus because it is decomposed less quickly than under wetter conditions. The factors of its formation are stated by Ramann to be high temperature and much evaporation in summer with, therefore, an ascending current of water that brings up salts from the subsoil; lasting soil frost in winter is also important as hindering decomposition of humus. Tchernosen occurs in patches in east Prussia and near Magdeburg, according to Ramann. Black earth grades northward in Russia into forest grey soil, and some of this is degraded black earth, being either due to increased leaching when forest was removed, or due to increased leaching with the advent of a moister climate after the hard conditions of the Pleistocene age passed. Black earth grades into chestnut brown soils on the warmer and still more arid regions of south Russia where plant growth and humus formation is less, and lime, etc., are brought at least as far up as the deeper layers.

In south Europe with its warm dry summers and strong evaporation the amount of hydroxides of iron, brought up by the upward current of water and formed by fairly rapid chemical action under the warm conditions, makes the soils reddish, while humus is quickly decomposed when there is moisture because the rainy season is not cold, and so the humus content is low. If, because of very strong evaporation, the soil contains soda and is alkaline it appears that colloidal humus compounds are maintained and leaching of iron compounds goes on, thus giving grey soils of a special character in steppe lands. These grey steppe-soils are characteristic of central Spain as well as of Turkestan, etc. They naturally grade into soils with a large content of salt, such as are found in south-east Europe and in some lands of the southern Mediterranean, and something of their type occurs in south and south-east Spain. The black earths are invaluable agriculturally because they need less organic food than the brown ones. The forest grey soils are distinctly poorer. The red earths need organic food if they are to grow crops with roots near the surface, but they rather lend themselves to the growth of deep-rooting plants which, again, are suited to the climate with its long dry season during which plant roots near the surface could not get enough water. The local sedentary red soils over the red sandstones of western Europe also give conditions highly suited to fruit trees and the like with deep roots. The local transported soil called loess, covered in large parts of Russia by black earth (Tchernosen), is highly porous with a good salt content from the upward current of water in it under dry conditions, and it often retains a fairly considerable humus content. Its looseness and porosity are not favourable to heavy growth of trees and it has been seized upon by man from early times for agricultural settlements.

VEGETATION ZONES

The vegetation of Europe is set in extensive zones which depend mainly on the zones of climate, partly in a direct fashion and partly through the influence of climate upon the soil (*see* above). Behind the influences of present conditions there are vestiges of the influences of former conditions of climate, discussed especially by C. E. P. Brooks in *Evolution of Climate*, (1915), and Gams and Nordhagen in *Postglaziale Klimaänderungen* (München, 1923).

The region of Mediterranean climate is characterized by the presence of the olive, the cultivation of which spread from coasts or islands of the eastern part of the sea. The distribution basin is wider and reaches farther from the coast around the western basin than around the eastern. Among limiting factors on the north is the cold of winter in the highlands, even near the coast; in the south-east the heat becomes too great for the olive as it becomes sufficient for the date palm. A noteworthy point is that northern Castile in Spain has very little if any olive, nor has the Garonne basin; but the Ebro basin and that of the lower Rhône below Pierrelatte have a great deal of it. Again the Po basin has very little olive save in certain districts beneath the Alps. It is very much of a coastal plant in the Balkan peninsula save to some extent in Greece. It occurs along the coasts of the south-east of the Black sea. It is important especially in the lowlands in Palestine and Syria.

The zone of western, oceanic or sub-oceanic climate, the zone of the humid brown earths, is just as strikingly characterized, at the present time, by the beech-tree (*Fagus sylvatica*). This lives in Castile and the Garonne basin, but, farther to the south-east, occurs only on mountains where the summer temperature, and consequently the evaporation, are not too great. The zone of beech has specially lent itself to agricultural improvement in recent centuries, with the development of root-crop feeding stuffs for beast and man (especially, now, the sugar-beet) and the spread of the potato which has done so much to increase the population of the European plain from Holland to Poland. The zone of oak-without-beech is in the main a fringe of the beech-zone northwards. It includes the lake zone of south central Sweden and the south-west corner of Finland, both regions which stand out as much more developed than those next farther north, for in this zone of Sweden is Stockholm and in this corner of Finland are Turlu (Åbo) and Helsingfors. The ash reaches a little farther north than the oak. Eastwards the oak spreads far beyond the beech especially on the forest grey earths north of the black earth, in the wedge of summer rain that has its base on the Vistula-Dniester line and its apex at the line of the Urals. The beech stops about the line from Königsberg to Kherson but it appears in the Caucasus. It is the Russian zone of oak-without-beech that is the essential "Great Russia" with its traditionalist agriculture; it is separated from western Europe not only by the fact that it lacks the beech and the humid brown earth, but also by the sheer physical obstacle of the Pripet marshes, and the marshes stretching southward from the region of Lake Peipus.

North of the zones of beech and oak is the region of *Pinus sylvestris*, the region of cold soils in which root action is necessarily slow, and of cold air in which evaporation is also slow. The pine forests are adapted to these conditions, the leaves are resin-protected and tough, and do not let water evaporate faster than the slow-working roots can absorb it from the soil. Often enough an area of pine forest in the north is not worth reclaiming for agriculture but sometimes barley and rye can be grown and it is to be remembered that the removal of forest raises the summer temperature of the soil very distinctly. The pine and birch dwarf gradually towards the north where the deeper layers of the soil rarely unfreeze, and in this way the forest grades into tundra and the mossy-hillocks of the Arctic, the former with quick growing herbaceous plants flowering in the short summer season. Many minor points might be discussed such as the creep up the west coast of Europe of the holly (*Ilex aquifolium*) which has spread right into mid Germany, of the evergreen oak which reaches as far north as Brittany save for specially sheltered spots beyond. The invasion of the Alpine mountain system by Asiatic species of *Cytisus* since the end of the Ice age is an interesting matter and the Alpine system is also characterized in a high degree by the larch (*Larix europaea*).

The Mediterranean region has many plants with tough or hairy drought-resisting leaves which develop, not in one burst, as farther north, but slowly at all times, being thus free of dependence on rain at a particular season. Olive, oleander, myrtle, laurel are characteristic and the woodlands include chiefly evergreen oaks, Aleppo and other pines and silver poplars. On the mountain ranges the plants of the "beech zone" of Europe penetrate southward. Bush covers large areas and includes large growing heather, arbutus, myrtles, laurels, pistachio and many strong scented labiate plants; in dry spots, as in Spain, this bush formation, called *Macchia* in Italy, grades into pure heath. The French word *Maquis* connotes a heath land with shrubs in its general acceptance. The Mediterranean regions which cannot support these tree and brush growths may be covered by a mat of grass and bulbous plants, plants which can maintain life underground when the dry season makes their leaves wither; in dry parts of Spain the alfalfa grass is an important feature. The Mediterranean has been famed for its fruit from the dawn of history. The vine, furnishing rich wines in the west and chiefly currants and raisins farther east, is an important plant save in the south-east in Asia where Islam and the unsuitability of the climate for maturation of wines combine to limit production. The citrous fruits introduced long ago from the monsoon lands occur in the more sheltered and better watered tracts and their presence is often an indication of a favoured locality. In the irrigated gardens of East Spain (Valencia) oranges are grown on a large scale. Almonds, figs and pomegranates are other notable fruits. The date palm grows in a few specially warm spots.

The beech and oak-without-beech regions of Europe became forested, apparently, first with pines and then largely with oak and elm, ash and thorn when the steppe conditions of the Pleistocene passed away, and the sinking of coasts in western Europe helped to bring in oceanic influences on climate. The beech may have lived near the Atlantic and Clement Reid speaks of beech leaves found in early post-Pleistocene deposits in England; it spread, apparently, during the last millennium or two, B.C., and is much mixed with these other characteristic trees in many parts. The region is thus one which was heavily forested before man cut the trees. But some areas of thin soil on porous rocks and the areas of loess in the Danube basin, under Carpathians, Czechoslovakian mountains, Thuringian hills and Harz, and in the Neckar, Alsace and Rhein-Hessen lowlands were apparently not at all densely wooded. In Belgium, northern France and East Anglia soils related to loess and described by the French as *limons de plateau* were also apparently fairly free. These areas thus became important early centres of settlement and have remained important agricultural areas ever since. The coastal dunes and marshes and the windswept coastal plateaux have also been free from forest since present conditions were established and among them heath plants, gorse (*Ulex*) and bracken (*Pteris*), the latter on the more rocky areas, are highly characteristic.

The steppe region of south Russia has trees for the most part only quite near rivers, and they are chiefly willows, alders and poplars. The period of growth after the passing of winter and before summer heat dries everything up is reduced to about three months (April 15 to July 15). Herbaceous quick growing plants and especially those with underground food stores are characteristic, and often one finds very large numbers of a particular plant together, offering a contrast to the rich mixture of species in many of the plant associations farther west. The chief plant is the grass *Stipa* with specially tough stalks and narrow rolled leaves, but labiates and composites are also widespread. Towards the Caspian, and in analogous spots elsewhere, salt-loving plants are a feature. There are a good many thorn shrubs mainly of the order of the leguminosae. The northern region of pines also has birches and willows among its trees, with grasses, ranunculaceae, heather plants, cruciferae and saxifrages conspicuous among its herbaceous plants. Mosses, liverworts and lichens are a marked feature.

Fauna.—Animals in Europe and the Mediterranean region are, or were until men reduced their numbers, of many kinds related to those of lands farther south or farther east, and the name Palaearctic has often been given to the region including Europe and most of Asia north of the Himalaya, as a region with a distinctive fauna of forest and steppe. The fauna of Pleistocene Europe is a matter of archaeological interest but it is useful to interpret certain features of the life of a few regions, still fairly wild or only recently adapted by man, as remnants of an ancient fauna. It is, for example, claimed that the truly wild steppe-horse survived in the Vosges until the middle ages and the Saiga antelope, a sheep-like animal lingers east of the Volga while the Urus has left some of his blood at least to wild cattle that were formerly widespread in forest glades and that still linger here and there. The Mouflon perhaps in part the ancestor of some breeds of sheep, survives in Corsica, Sardinia, Crete, Cyprus and the Taurus mountains. The brown bear, wolf, fox, otter and badger are the chief of the larger carnivores that survive in Europe but the wild cat still lingers. The deer of Europe are for the most part distinct from those of Asia and do not extend far into Russia. The chamois, a member of the antelope group, is peculiar to Europe and lingers in the high Alps and Caucasus, and the musk-rat and related desman are confined to the French Pyrenean slopes and the Don and Volga banks respectively. Moles are highly characteristic of the region and some genera are confined to it.

Boyd Dawkins and others following him have interpreted the present European fauna as the result of immigration both from the south across former landbridges, and especially a landbridge between Sicily and Tunis, and from the steppes of central Asia, and it is probable that both sets of migrants have contributed to the domestic animals of Europe. It has been suggested that the Soay sheep and the so-called Celtic pony are mainly southern in ancestry, while Asiatic races of sheep, cattle and horses have displaced almost completely the southern ones, presumably earlier immigrants along the west. Doubtless the intermixture with local wild forms, especially of cattle and swine, has had much to do with the evolution of existing types of these animals as domesticated in Europe and its borders. The spread of the rabbit from the Mediterranean as far north as Britain and Germany in the middle ages is a noteworthy feature of European animal life entirely due to man. The spread of the brown rat at the expense of the old European black rat is another feature of man's influence in recent centuries, this time an undesigned influence.

AGRICULTURE: EARLY AND MODERN

Settled life in Europe has for long been based primarily on the cultivation of cereals; and of these wheat and barley, at least in the forms in which they are cultivated, are believed to be introductions from south-west Asia and were spread in Europe in the third millennium B.C. largely by way of the Danube basin but possibly also by maritime communications along the Mediterranean and Atlantic coasts. Though wheat and barley are the older food plants, rye has become a crop of great importance especially north and east of the Rhine, the Austrian Alps and the Carpathians and in Russia north of a line running from lat. 44° N. in the west to lat. 55° N. in the Ural mountains. It is often said that a fundamental contrast in peasant life between France and Germany is that between wheat and rye, though much wheat is grown in Germany. The proportion of wheat to rye in France is 8¼ to 1, in Germany 1 to 2½, in Hungary more than 2½ to 1, in Poland 1 to 4. In both Austria and Czechoslovakia there is more rye than wheat. Rye is more tolerant of cold than is wheat, and is a food producing more bodily heat. Belgium on the wheat side of the Rhine produces more rye than wheat at present. Barley is a specially adaptable crop giving a good yield of straw in the south in some Mediterranean regions and yielding grain in some places too cold for useful wheat cultivation. Oats are cultivated in most European countries and are produced in greater quantity than wheat in the British Isles, Belgium, the Netherlands, Denmark, Norway, Sweden, Finland, Estonia, Latvia, Lithuania, Germany, Austria, Czechoslovakia and Poland. In most of these countries, however, except the British Isles, Denmark, Norway, Sweden and Finland, the amount of oats appears to be less than that of wheat and rye combined. It is thus a crop adapted to the cool moist north-west in which it gives a harvest earlier than does wheat, while in Poland the oats harvest is after that of wheat.

Archaeological studies have suggested that the earliest agricultural scheme was one which still prevails in some parts of Africa, in a few backward regions of India and in north Korea, etc., where a group of villagers cultivates a patch of soil until it is exhausted and then moves on. This was apparently quite early superseded by the more settled village with some scheme of rotation for use of the fields of the village. There is increasing probability that some areas especially on the loess have been continuously utilized in this manner for thousands of years. The fertility of the soil has been renewed by fallowing and by manure from stock as well as by the ploughing-in of leguminous crops which enrich the soil in nitrates formed from the atmosphere by root nodules of plants of this order.

Within about the last three centuries schemes of cultivation have been much modified by the spread of root-crops (parsnips, turnips, mangold wurzels, forage beetroots), which grow on into the autumn in western Europe and provide winter food for farm animals. The spread of these crops is generally held to have had a powerful influence in modifying traditional agriculture, one feature of which was the pasturing of cattle on the stubble of the fields after cutting of the corn harvests in order to manure the land. The root crops left in the ground for some time after the corn harvests prevented the use of the land in this way. Root crops gave additional food for man and beast and by increasing the number of animals helped to make more flesh food available for man, and also gave more leather.

The spread of the potato has made great changes in European life, it has become a great food crop in Norway, north Germany, Czechoslovakia, Poland, the lands of the south-east Baltic, in most of which countries the weight of the crop exceeds that of all the cereals combined. The potato has become important also in Russia where the weight of the crop is now nearly equal to the sum of the weights of the wheat and the rye crops. The potato is however tolerant enough to form a fairly important crop in France, Italy and Hungary as well. Its importance in Ireland is well known. It has clearly played a considerable part in promoting increase of population in Ireland, and on parts of the European plain, notably in Prussia, where the soil is cold and impervious. The sugar-beet has further increased European food supplies and is important in Italy, north France, Belgium, the Netherlands, Germany, Czechoslovakia, Hungary, Poland, Russia and Rumania. The introduction of maize from America, to be cultivated for the most part after the fashion of European cereals rather than as it was originally grown in America, has been important especially for south and east France, Italy, Hungary, Yugoslavia, Rumania, and parts of Russia.

The break up of traditionalist agriculture led to experiments in the direction of improvement of vegetables, and the growth of modern bulk-transport has further changed the situation by liberating countries from complete dependence on their own products, and by making available imported fertilizers such as chili saltpetre (nitrate of soda) and guano; while the rise of chemical industries, added to that of bulk commerce in palm products from the equatorial zone, has increased the variety of fertilizers and of animal foods which produce fertilizers. The present crop-production of a country may thus be far from a result of the soil and climatic features of the country concerned. In Britain the precariousness of wheat harvests in many parts has played a part along with other factors in the decline of the crops grown, while France with its more assured sunshine in summer has remained more substantially agricultural. Germany, industrialized later than Britain, has done more to maintain its agriculture, and in this effort the application of science to the making and using of manures, imported or manufactured, has been an important factor. All these modern changes in cultivation have tended to emphasize the independence of each farm and there has been a marked tendency among rural populations towards scattering of homesteads, towards the "single farm" rather than the "nucleated village" type of habitation or, in the French terminology, towards the *habitat disperse* as contrasted with the *habitat concentré*. Along with this however there have grown up schemes of co-operation among agriculturists which are well known in Denmark but are developed in various degrees in several other countries. Areas of specially high cultivation have developed in the last half century, notably in Holland, around Paris, in North Brittany and the Channel Isles, in Provence, Lombardy, etc. Among other food crops may be mentioned buckwheat grown in France, especially in the west, and northward to Denmark, as well as in South Russia, lentils in France and the adjacent parts of Germany and millet in Russia. Sugar cane is cultivated to a small extent in Spain and Sicily and rice is largely grown in the basin of the Po.

The vine is a plant the stock of which can withstand a certain amount of cold while its roots need a fair supply of water and well drained soil, and sunshine is important for growth of the fruit. Its effective northern limit is lat. 47½° on the Atlantic coast, 50°–52° in Germany and much farther south in Russia. The fruit, and the wines made from it, differ greatly in different regions, being rich in sugar and giving heavy wines in south Spain and Portugal, for example. Towards the effective limit, *i.e.*, in general north of the central plateau in France and north of the Jura in Switzerland, vineyards are for the most part highly specialized as it is now no longer worth while to make inferior wines on a large scale under the difficult conditions near the practical limit.

Thus Saumur, Champagne, Moselle, Hock, Tokay, are, in the main, "choice" wines, as are many of the Burgundian vintages. Formerly the vine was grown farther north and its importance for the Sacrament of Holy Communion promoted this; it can actually grow and even on occasion ripen as far north as sheltered spots of southern aspect in south Norway, thanks in part to the long duration of summer sunlight.

The zone north-westward beyond that of the vine in France, and the red soils in England have the cider apple, and in England, Belgium, Germany and Austria hops are cultivated for beer. Farther east the tendency is rather to distil spirit from grain or potatoes. The combination of stock-raising with crop growing varies in different parts of Europe but is on the whole far more characteristic of what may broadly be called north-west Europe than it is of Mediterranean lands or of Russia, *i.e.*, it is developed especially in those countries where rain falls at most seasons and pastures are rich and root crops thrive. The plateau lands of the Iberian peninsula are, however, famous for their sheep, which are moved over long distances from pasture to pasture as the seasons change (*transhumance*); and Greece has many sheep, and Italy a considerable number of cattle. Intensive methods give interesting results in certain cases.

	Horses (per square mile)	*Cattle* (per square mile)	*Swine* (per square mile)
Denmark	31	176	225
Netherlands	29	164	120
Belgium	21	150	97

Only Hungary and Germany rival these figures as regards horses and they are far behind these countries in cattle and swine. Germany has 120 swine and is rapidly increasing their number, and 21 horses, but only 96 cattle per square mile. England and Wales are interesting in this respect with 19 horses and 107 cattle but only 38 swine; they have, however, 289 sheep as against 22 in Germany and 50 in France and only a very few in Denmark. Switzerland has a high average for cattle but stands relatively low in pigs and quite low in horses and sheep. The Irish Free State also stands high in the matter of cattle, but is far behind the countries listed above in pigs and horses; it has however a considerable number of donkeys which are also a feature in Italy and Spain and Portugal and Greece. The breeds of these animals vary from country to country, sheep for wool and sheep for mutton, cattle for draught, for dairying or for beef, horses for riding or for draught and so on. The cattle for dairying and those for beef are chiefly those of the rich pastures favoured by Atlantic rains and among dairy breeds Frisians, Jerseys and Guernseys have wide renown. The buffalo is used in Rumania and southern Italy. The pig is important in the old kingdom of Serbia though the statistics for the whole of Yugoslavia do not give quite 30 per square mile. The goat is important in Greece, Italy and Spain and Portugal and also abounds in the hilly parts of Germany.

Reference has been made above to fruits and it is necessary only to summarize by mentioning the olive, grapes, figs, apricots, peaches, pomegranates, and citrous fruits of Mediterranean lands, the plums and cherries of France and central Europe, with a special mention of Yugoslavia here, as well as the specialized vineyards of central and north-eastern France, the Rhine and Hungary, the apples and pears of France and parts of Britain. The fibre-crops cultivated in Europe were formerly more widespread than now that exotic fibres are imported and artificial ones made. Flax, however, remains important in Flanders and is still grown in northern Ireland, in north Italy and in Russia towards the north. Hemp is fairly widely grown in Russia and in parts of central Europe and France. (H. J. F.)

GEOLOGY

The geological history of Europe is, to a large extent, a history of the formation and destruction of successive mountain chains. Four times a great mountain range has been raised across the area which now is Europe. Three times the mountain range has given way; portions have sunk beneath the sea, and have been covered by more recent sediments, while other portions remained standing and now rise as isolated blocks above the later beds which surround them. The last of the mountain ranges still stands, and is known under the names of the Alps, the Carpathians, the Balkans, the Caucasus, etc., but the work of destruction has already begun, and gaps have been formed by the collapse of parts of the chain. The Carpathians were once continuous with the Alps, and the Caucasus was probably connected with the Balkans across the site of the Black Sea. There was, however, a large area which was not involved in the folding that produced these ranges, except, perhaps, the earliest. In the eastern part of Scandinavia and throughout the greater part of Russia even the Cambrian beds are nearly horizontal and there has been no folding since archaean times. This resistant area constitutes the Baltic Shield and Russian Platform of Suess. It extends eastwards to the Timan range and Ural Mountains, southwards to the folded belt of the Sandimir Wald and the Donetz, and north-westward to the mountain axis of Scandinavia.

The oldest mountain chain lay in the extreme north-west of Europe, and its relics are seen in the outer Hebrides, the Lofoten islands and the north of Norway. The rocks of this ancient chain have since been converted into gneiss, and they were folded and denuded before the deposition of the oldest known fossiliferous sediments. The mountain system must therefore have been formed in pre-Cambrian times, and it has been called by Marcel Bertrand the Huronian chain. It is probable that a great land-mass lay towards the north-west; but in the sea which certainly existed south-east of the chain, the Cambrian, Ordovician and Silurian beds were deposited. In Russia, as we have seen, and South Sweden these beds still lie flat and undisturbed; but in Norway, Scotland, the Lake District, North Wales and the north of Ireland they were crushed between the north-western continent and the Baltic Shield. Not only were they intensely folded but they were also pushed forward over the old rocks upon each side. Thus was formed the Caledonian mountain system of Ed. Suess, in which the folds run from south-west to north-east. It was raised at the close of the Silurian period.

Then followed, in northern Europe, a continental period. By the elevation of the Caledonian chain the northern land-mass had grown southward and now extended as far as the Bristol Channel. Upon it the Old Red Sandstone was laid down in inland seas or lakes, while farther south contemporaneous deposits were formed in the open sea.

Carboniferous Period.—During the earlier part of the Carboniferous period the sea spread over the southern shores of the northern continent; but later the area again became land and the coal measures of northern Europe were laid down. Towards the close of the Carboniferous period the third great mountain chain was formed. It lay to the south of the Caledonian chain, and its northern margin stretched from the south of Ireland through South Wales, the north of France and the south of Belgium, and was continued round the Harz and the ancient rocks of Bohemia, and possibly into the south of Russia. It is along this northern margin, where the folded beds have been thrust over the rocks which lay to the north, that the coalfields of Dover and of Belgium occur. The general direction of the folds is approximately from west to east; but the chain consisted of two arcs, the western of which is called by Suess the Armorican chain and the eastern the Variscan. The two arcs together, which were undoubtedly formed at the same period, have been named by Bertrand the Hercynian chain. Everywhere the chief folding seems to have occurred before the deposition of the highest beds of the Upper Carboniferous, which lie unconformably upon the folded older beds. The Hercynian chain appears to have been of considerable breadth, at least in western Europe, for the Palaeozoic rocks of Spain and Portugal are thrown into folds which were formed at approximately the same period. In eastern Europe the evidence is less complete, because the Hercynian folds are buried beneath more recent deposits and have in some cases been masked by the superposition of a later series of folds.

The formation of this Carboniferous range was followed in northern Europe by a second continental period somewhat similar to that of the Old Red Sandstone, but the continent extended still

farther to the south. The Permian and Triassic deposits of England and Germany were laid down in inland seas or upon the surface of the land itself. But southern Europe was covered by the open sea, and here accordingly, the contemporaneous deposits were marine.

Jurassic and Cretaceous Periods.—These periods were free from any violent folding or mountain building, and the sea again spread over a large part of the northern continent. There were indeed several oscillations, but in general the greater part of southern and central Europe lay beneath the waters of the ocean. Some of the fragments of the Hercynian chain still rose as islands above the waves, and at certain periods there seems to have been a more or less complete barrier between the waters which covered northern Europe and those which lay over the Mediterranean region. Thus, while the estuarine deposits of the Upper Jurassic and Lower Cretaceous were laid down in England and Germany, the purely marine Tithonian formation, with its peculiar fauna, was deposited in the south; and while the Chalk was formed in northern Europe, the Hippurite limestone was laid down in the south.

Tertiary Period.—The Tertiary period saw fundamental changes in the geography of Europe. The formation of the great mountain ranges of the south, the Alpine system of Suess, perhaps began at an earlier date, but it was in the Eocene and Miocene periods that the chief part of the elevation took place. Arms of the sea extended up the valley of the Rhône and around the northern margin of the Alps, and also spread over the plains of Hungary and of southern Russia. Towards the middle of the Miocene period some of these arms were completely cut off from the ocean and large deposits of salt were formed, as at Wieliczka. At a later period south-eastern Europe was covered by a series of extensive lagoons, and the waters of these lagoons gradually became brackish, and then fresh, before the area was finally converted into dry land. Great changes also took place in the Mediterranean region. The Black Sea, the Aegean, the Adriatic and the Tyrrhenian Sea were all formed at various times during the Tertiary period, and the depression of these areas seems to be closely connected with the elevation of the neighbouring mountain chains.

Exactly what was happening in northern Europe during these great changes in the south it is not easy to say. The basaltic flows of the north of Ireland, the western islands of Scotland, the Faeroe islands and Iceland are mere fragments of former extensive plateaus. No sign of marine Tertiary deposits of earlier age than Pliocene has been found in this northern part of Europe, and on the other hand plant remains are abundant in the sands and clays interbedded with the basalts. It is probable, therefore, that in Eocene times a great land-mass lay to the north-west of Europe, over which the basalt lavas flowed, and that the formation of this part of the Atlantic and perhaps of the North Sea did not take place until the Miocene period.

At a later date the climate, for some reason which has not yet been fully explained, grew colder over the whole of Europe, and the northern part was covered by a great ice-sheet which extended nearly to the Thames in England and as far as 50° N. in Russia, and which has left its marks over the whole of the northern part of the continent. With the final melting and disappearance of the ice-sheet, the topography of Europe assumed nearly its present form. Minor changes, such as the separation of Great Britain from the continent, may have occurred at a later date; but since the Glacial period there have, apparently, been no fundamental modifications in the configuration of Europe.

The elevation of each of the great mountain systems already described was accompanied by extensive eruptions of volcanic rocks, and the sequence appears to have been similar in every case. The volcanoes of the Mediterranean are the last survivors of the great eruptions which accompanied the elevation of the Alpine mountain system.

Soc. Géol. France*, ser. 3, vol. xvi. (1887–1888), pp. 573–617. A readable summary, intelligible without much previous knowledge of geology, will be found in *The Growth of Europe* by G. A. J. Cole. The *Kleine geologische Karte von Europa*, issued by the Prussian Geological Survey, with its transparent covering sheet *Tektonisches Bild von Europa* will be found helpful. (P. LA.)

ARCHAEOLOGY

EASTERN EUROPE

General Description.—Eastern Europe includes the wide plain of European Russia, bounded by the Arctic ocean, the Urals, the Caucasus and the Black sea together with Rumania east of the Carpathians and Bulgaria north of the Balkans; the western boundary might find a better physical basis in the White sea, the lakes Onega, Ladoga and Ilmen, and then the Carpathians and the backbone of the Balkans peninsula. To the east there is no real boundary but the Urals and the Caspian. The history and archaeology of this territory are unintelligible, unless we call to mind that it is divided into belts running east and west and each characterized by special vegetation, the product of its climate and soil. The northern belt of tundra hardly comes into archaeology; below it runs the broad expanse of fir and spruce forests down to a line going east-north-east from Berdichev, by Kiev, Orël, Tula, across the junction of the Volga and Kama south of Kazan to the Urals, where it dips down almost to Orenburg. The next belt is of mixed deciduous trees and open ground, from Kishinev (Chişinaŭ) in Bessarabia to Saratov on the Volga, along it to Samara and across to be interrupted by the Ural woods. South of this is open steppe as far as the sea; as we go south and east the steppe gets more and more salt, so that most of the government of Astrakhan is desert.

The conifers grow on the area which was formerly glaciated; the subsoil to the south of this is loess, covered in the deciduous belt by the rich deposit known as *chernozëm*, black-earth. All these belts are continued into Siberia except so far as the Ural forests interrupt them; so the loess and the steppes appear in the west beyond the Carpathians. The Crimea is half of it steppe, but its mountains have a Mediterranean forest flora, like a piece of Greece. So the Caucasus with its southern flora is no part of Eastern Europe, but its fertile foot-hills with many rivers flowing into the Kuban and Terek are to be taken with the great plains to the north. And essentially it is all plain; the mountains are upon the boundaries, the only hills are either old moraines, or the low limestone ridge which without rising to any height deflects to the eastward the rivers Dnieper, Donets and Don. These rivers, with the Danube, the Pruth and the Dniester to the west and the Volga to the east, are the chief landmarks in the plain, but have never served as permanent frontier defences.

With such a structure the country offers in its northern forests and its southern mountains refuges in which backward tribes have maintained themselves almost undisturbed for untold ages, but the fertility of the middle strip of black earth has attracted settlers, and the steppes below have been not so much a place for settlers as a corridor in which, as far as history goes back, tribe has succeeded to tribe, each holding it for less and less time, perhaps as the woodlands in the steppe grew less, until by about the 17th century the mutual raids of Muscovites, Cossacks and Tartars had almost depopulated it. Most of these historical movements came from the East, but there have been enough from the north-west to show that we must not assume the westward movement to be a universal law. From the south-east cultural influences have ascended the Volga or crossed the Ural steppe to the northern forests. From the south influences from Hither Asia penetrated through the Caucasus, and commercial settlers on the south coast, Ancient Greeks, Mediaeval Genoese and Western Europeans in modern times, have affected the southern part of our area.

Palaeolithic man appears in Eastern Europe in Mousterian times; in Russia he occurs just at the edge of the ice-sheet and his remains are buried under the loess. There have been reports of many sites, but few have been published adequately, and mere descriptions are not convincing as there is much difficulty in correlating forms found in this Eastern area with the sequences established in the west. To the Moustier time are referred types from Izyum near the great bend of the Donets, from Kiik-Koba and Volchi Grot near Simferopol in the Crimea, from Ilskaya just north of the Caucasus and from Afontova Gora near Krasnoyarsk in Siberia. A good many sites are put down to the

Madeleine period, but it is perhaps more correct to say that there was no true Madeleine period in Russia, only a continuation of Aurignac. Such may be mentioned at Kiev, Cyril St., where was a mammoth tusk with engravings representing some sort of creature, something like the woman from Předmost in Moravia. From Mizin on the Desna came an ivory statuette of a woman, figures of birds and an ivory bracelet. The birds and the bracelet had upon them meanders and developed swastikas, the first known occurrence of these motives. At Kostënki in Vorónezh was found a statuette rather like the Solutré work; another late Aurignac site which must be mentioned is Hontsí or Gontsý in Poltava. A skull like those of the Aurignac period was found at Podkumok near Pyatigorsk, north of the Caucasus, and bones at Kiik-Koba; a skull like that from Galley hill occurred at Undory in Simbirsk government. The latest palaeoliths come from Karachárovo near Murom, being found in the substance of the loess.

This Eastern Aurignac stretches into Siberia to Tomsk, Irkutsk and Krasnoyarsk, and further to Shen-hsi in China. In Bulgaria palaeolithic finds occur at Malkata Peshtera in the Trnovo district and on the Moravitsa farther west.

In Mesolithic times there was the so-called Littorina lake, a kind of greater Baltic and kitchen middens on the Russian shores of it, *e.g.*, at Kolomtsy near Novgorod. The Tardenois microliths have been found in Poland, Lithuania, Southern Russia, on the kinghiz steppes north of the Caspian, and away into Siberia. Axes, not unlike the Campigny or the Nostvet types, occur in Olónets, about the Valdai waterparting and further south-east to Ryazán and the Oka. Thin butted axes and then the thick butted improvement stretch right across the north of Russia, and seem to point to Scandinavian affinities. To the same age belong bone harpoons and other bone points with inset flints, but these are not readily to be distinguished from neolithic; finally pottery comes in, and shows we have reached the neolithic stage.

Mesolithic finds are reported from Bulgaria. But these small flints are still used by fish-eating Tartars in Siberia, so dates must be assigned with caution, especially as we do not know how far behindhand these out-of-the-way regions may have been. Through a great deal of the time when North Russia was still neolithic, the southern countries were using copper, perhaps even bronze.

The neolithic types of North Russia are mostly reflections of Scandinavian or German work; the most interesting and peculiar have the butt end of an axe worked in the shape of an animal's head, quite well done sometimes, and the love of this survived into the bronze age. Farther south on the Valdai plateau and on the Oka at Bologóe, Balákhna and Volósovo, stations with abundant flints, bone work and pottery have been investigated. The pottery has impressions made with a stick, or thumb nails, the maggot pattern, and that of grass woven work. Before the wheel was invented it was probably a great help to make a pot within a wooden mould lined with a mat, pull it out with the help of the mat and peel this off, leaving the perfect pot. This kind of ware goes right across by Irkutsk to Japan, and the flints are also similar. Neolithic stations have been well examined about Bakhmut and Izyum near the bend of the Donets.

The transition to metal in Eastern Europe offers various interesting problems. The civilization of the black earth regions of South-west Russia, Podolia, Kiev, Poltava and Bessarabia, continuous with Galicia, Moldavia and Transylvania, and traceable through Bulgaria as far as Thessaly, seems to belong to Central Europe. It was contemporaneous with a very different life in the steppes and seems to have been destroyed by a western encroachment of steppe folk.

The great characteristic of the copper age in Eastern Europe is the occurrence not so much of objects in copper, which are mostly few and small, but of stone axes of usually admirable workmanship which in their details, *e.g.*, in a kind of raised collar about the shaft hole, must evidently have been modelled upon metal originals. Axes such as these go right across from Jutland to North Russia, then to South Russia and the Kuban region, to Bessarabia, Bulgaria, and appear among the rich metal wares of Troy II. They are evidently connected with the central European type of Marschwitz.

In the far north this stone-age culture seems an extension of the Scandinavian, and something the same may be true in North Central Russia, where in cemeteries of the Fatyanovo type we find globular vases such as may be traced westward into North Germany. Two chance finds at Galich and Seyma appear to show that Mesopotamian influences were reaching even so far north and crossing those from Finland. On the middle Donets and everywhere south of the forests this period is marked by the occurrence of skeletons, associated with lumps of ochre or other red colour. This ritual again goes right across into North Germany. Three phases of such tombs have been distinguished, pit graves, chambered pit graves and graves under wooden erections, and they seem to come in this order. On the open steppe the finds are very poor, but the size of the barrows argues that the dead men were great chiefs. In the Kiev regions red skeletons go with pottery, showing basket-like patterns, as at Yatskovitsa near Kiev. Elsewhere we have corded ware. A chance find at Borodinó in Bessarabia yielded four wonderful axes in jade and serpentine, limestone mace-heads and silver looped spearheads and pin; these objects had spirals upon them in gold plate. The work points to great progress in metal technique, and the things must have been mere insignia.

But it is along the north slope of the Caucasus that the red skeletons are accompanied by splendid grave goods which give some hope of dating them. Two barrows at Tsarevskaya contained dolmens, divided into two chambers by a holed stone. One dolmen had a roof made of two stones with opposite slopes, which looks like a translation of a wooden structure into stone, and so may be independent of dolmens in Western Europe or elsewhere. One of them contained a globular pot just like those from Fatyanovo.

A barrow at Ulski on the Kuban river yielded alabaster long-necked statuettes just like the well-known types from the Cyclades, also a model of a hut, which looks as if it were meant to be put on a waggon, so the people were apparently waggon dwellers such as the Greeks knew in the steppes. The richest barrow, opened in the town of Maikop, contained a man, a woman and a servant, all sprinkled with red. The chief had about him the remains of a canopy, gold and silver sticks threaded through oxen, vessels in gold, stone and clay, mostly of globular form, with almost cylindrical necks, in copper one flat axe and one holed axe, an axe-adze, a dagger, and a head-dress with golden ribbons and rosettes. One of the vessels had beasts upon it, also a real landscape, another only beasts, and upon the canopy were sewn gold plaques shaped as lions and oxen. All these beasts are in a naïf peaceful manner as different as possible from, say, the vigour of Assyrian art, but curiously like the friezes of beasts from Ur, or the predynastic Egyptian work which seems under Asiatic influence. Moreover, the holed axe is identical in form with the gold axe from Ur. These resemblances cannot but mean some influence exercised by early Mesopotamia, but they do not help us to assign dates; we have no reason to suppose that we have at Ur, *c.* 3500 B.C., the earliest examples of such work, whereas beasts as a subject come back again and again into oriental art and we cannot readily distinguish each recurrence as differing from all others in style. As we get away from our timekeepers in Egypt and Mesopotamia, at each remove dating becomes more uncertain. A good many things point to the painted pottery of South-west Russia coming down to about 1700 B.C. The red skeletons succeeded to it in that region, but no one can tell how long they had dominated the steppes to the east, and again there is nothing much to put between them and the Scythic culture which history ascribes to 700–200 B.C. Now these red skeletons look like the Indo-Europeans on their way to conquer Asia, whether coming from North Germany, as Tallgren and Kossinna would have it, or formed in South Russia, as Childe. They cannot well come from the north-west and be in the steppes in the third millennium, because the people in Jutland with similar axes and pottery only seem to belong to about 2200 B.C., about the date when battle-ax folk were ruling Troy II.

The first historical name in Southern Russia is that of the Cimmerians, who are reported to have invaded Asia Minor in 784 B.C.,

and certainly appeared south of the Caucasus in Sargon's reign (722–706 B.C.); in Assyrian they are Gimirrai and in Genesis Gomer. Under Esarhaddon (681–669) we find the Scyths mentioned as available for use against the Cimmerians, so we may put the expulsion of the Cimmerians from Southern Russia about 700 B.C. But of the Cimmerians archaeology can only say that objects which on other grounds belong to the time just preceding 700 B.C. may be assigned to the Cimmerians. It is not clear that they were anything but an earlier wave of Scyths, so that the most archaic "Scythic" things may be theirs, or again they may be part of the "red skeletons." One thing is certain: that the resemblances in name with Cimbri and Cymry are entirely illusory.

Mention must be made of the civilization best represented at Koban just north of the central Darial pass of the Caucasus, an early iron civilization (1100 B.C. and subsequently) making great use of bronze and showing most remarkable coincidences with Hallstatt types, grafted as it would appear upon a stock whose roots are south of the Caucasus; the European influence, if such there were, has left hardly any trace in the intervening steppe, and the Koban things do not journey west, save for perhaps a stray axe from Kerch or a bronze belt from near Kiev. Some influence from the west is marked by the few Hallstatt finds in Western Russia, antennae swords, fibulae and high-handled cups. Meanwhile in the Eastern Balkans the painted pottery people, whoever they were, were succeeded by tribes whom we may class as Thracians. Some of these began to pass over into Asia Minor by 1500 or so B.C. and others followed *c.* 1000 and *c.* 700, but they seem to have left little archaeological trace in Bulgaria.

In North-east Russia, upon the Kama, we find belated survivals of types known in Scandinavia (Malar axes) or in Southern Russia, and much use of stone continuing. In the steppes the coming of the Scythians means new light from Greek as well as Assyrian sources. (*See* SCYTHIA.) They seem to have come from very far East, with a culture formed under influences from Iran and Mesopotamia which they handed on to Siberia and even China. By about 300 B.C. they were giving way to a new wave of Eastern nomads, the Sarmatae, undoubtedly Iranians; instead of the Scythian bow and dagger, they used long spears and swords and wore coats of mail; we can see their outfit upon frescoes and grave slabs of the Bosporan kingdom on the Straits of Kerch, and graves with similar equipment occur along the Kuban, and in the region south of Orenburg, and spread steadily westwards. They brought with them a new development of the beast style marked by a strong taste for bright-coloured stones, especially garnet and turquoise. This influence extended even to the northern backwaters. The bronze age in north Russia had passed into the Anan'ino culture on the Kama, with iron, bronze and stone all used together until about the Christian era. In it the peculiar taste for beast-headed axes lived on. Upon the Upper Yenisei round about Minusinsk, and later Krasnoyarsk, a bronze culture had developed almost in isolation since before 1000 B.C. For the next 500 years it was almost cut off, though a few western influences penetrated; in the last 500 years B.C. it was strongly influenced by the Scythic beast style, not so much from Southern Russia as from some more easterly focus, and yet the antennae sword of Hallstatt seems first to have affected the Scythic dagger and then the Siberian. Apparently a Siberian invention is the curved knife with a ring on the end of the handle, which is regarded as the ancestor of the Chinese knife money.

The Sarmatian style went right across the north of Asia; specimens of it, both daggers and decorations, have been found in Korea in graves of about our era, and at the same date Mongolian graves north of Urga contained even textiles, with beast motives exactly like the gold work of Western Siberia (now preserved mostly in the Hermitage in Leningrad, but collected for Peter the Great), Southern Russia and even Hungary, into which the Sarmatians penetrated in the first centuries A.D.

But the current was not only westwards. La Tène finds in south Bulgaria begin about 300 B.C. and La Tène II. swords occur in Rumania, and so in Western Russia about Kiev both periods are represented; this means the historical raids of the Kelts and later the Germanic Sciri and Bastarnae. These must have crossed the territory of the Getae and Daci, Thracian tribes whose well built settlements have been investigated by Pârvan. With the extension of the Roman power to the Balkans the archaeological interest takes a new character as part of the archaeology of the Roman provinces rather than of Eastern Europe. In the same way the remains of the Greek cities along the Black sea dating from the 7th century B.C. are a province of Greek archaeology; we need only say that their interest for students of sculpture and architecture is small, but for ceramics not negligible, for painting quite important, and for textiles, woodwork and jewellery almost unrivalled.

Roman coin finds are common in Russia from just before A.D. 100 until just after A.D. 200, and penetrate up to Scandinavia. The end of them coincides with the arrival of the Goths upon the Black sea. To these are assigned graves (not in barrows) containing wheel-made pots, silver fibulae, bronze buckles, bone combs, glass beads and vessels, and of course iron weapons. The fibulae develop from the La Tène II. type with recurved foot and assume the familiar cross-bow, five-knobbed, square-headed and other forms of Teutonic use. But their origin seems to be in South Russia. This is the Sarmatian taste developed by the half-Sarmatian craftsmen of the Bosporus, adopted by the Goths, spread by them all over Europe and handed on to the other Germanic tribes, together with a form of beast style that radically changed the earlier Germanic beast style, itself perhaps not free from Scythic influence. One section of the Goths penetrated the Caucasus, and their cemetery is at Rutkha on the northern slope; others stuck in the Crimea and survived until the 17th century. The richest Gothic cemetery is at Gurzuf; similar things are found in the Balkans as far south as Chataldzha by Constantinople. A Gothic kingdom seems to have maintained itself upon the Dnieper until the middle of the 6th century, succumbing to the Avars, and there was another settlement upon the Oka.

Meanwhile the native Finnish cultures of the centre and north of Russia went on repeating old types, very much behind the times, and occasionally accepting and simplifying imported designs, applying them to strange cast bronze figures in which the Scythic beast style survived in a degenerate form. These had some use in Shamanist cults, which also required great silver dishes imported from the south and paid for in furs. Hence it comes about that, besides Greco-Roman and Byzantine plate, the recesses of Perm have furnished the greater part of the surviving specimens of Sassanian silver work. In Central Russia the people lived in fortified villages of the type called D'yakovo.

The Huns in the 4th and 5th centuries were forerunners of swarms of Asiatics, mostly of Turkish race, who passed along the corridor. Coming from the north-east they often divided the inhabitants and forced part into the Caucasus and part westwards; this happened to the Goths and to the Alans whose descendants survive in the Ossetes of the Central Caucasus, and later to the Magyars. To the Huns succeeded the Avars, fleeing from the Turks in the 6th century and the Bulgars in the 7th; then came the Magyars in the 8th century, Finno-Ugrians under Turkish influence, of whom the Bulgars left some part of their nation to develop into a civilized state at the confluence of the Kama and Volga, where their buildings have lately been excavated; Khazars, Pechenegs, Cumans and finally the Tartars in the 13th century, each came in from the East and most were forced out to the west, Bulgars into the Balkans, the others into Hungary. Archaeologically we note these peoples by the development of oriental metal work, especially in horse trappings buried in their barrows, and by great hoards of loot that they or their victims hid and never recovered, such as the Pereshchepina hoard amassed by an Avar chief, the Nagy Szent Miklos treasure with its Bulgar inscriptions, or the many hoards buried by the Russians at the coming of the Tartars.

Again, we must not forget the less catastrophic and more important western currents, above all the Slavs, who must have been spreading from the Carpathian countries under the Gothic rule, but have left singularly little trace by which we can distinguish them from Finns; certain semi-circular ear-rings, and

particular pots are put down as Slavonic because of their western analogues. Most of the objects found in graves of settled people show a mixture of Scandinavian and Arab influence, and the Arab coins are most important, going up the Volga to Scandinavia. With the conversion of the Russians to Christianity their things become more interesting, and the ear-rings develop into the well-known *kolts* often with enamel imitated from the Byzantine. In recent years much has been done to investigate the remains of pre-Mongol Russia. The Tatar invasion may be taken as the final point, but the Finns to the north continued till very recent times to bury with elaborate grave-goods after the ancient tradition.

CENTRAL EUROPE

Frontiers.—Central Europe is divided effectively from the Mediterranean and Atlantic regions by the Alps and Illyrian-Balkan ranges. On the east the Carpathians and the Transylvanian mountains border the Hungarian plain, without, however, constituting an ethnic frontier. To the north the Riesen and Erzgebirge are pierced by so many passes that the real cultural divide has always lain beyond the mountains near the terminal moraines of the last ice-sheet. Within the area thus defined the Danube, the Elbe, the Rhine and their tributaries form natural ways of communication, easily accessible from one another and so unifying the whole region. On the other hand, the great Middle Danube-Tisza plain is really contrasted with the more broken country further north that is separated from it by the complicated ranges of Slovakia and the eastern spurs of the Alps.

In late glacial and postglacial times the löss, clothing the slopes, but neither the higher hills nor the low-lying plains, was the main unifying factor; it provided a series of relatively open strips linking the middle Danube to the northern plain and the Rhine valley. The forests, which constituted the most serious barrier to early human settlers, fringe the Central European löss belt, but do not interrupt it by any really impassable transverse stretches.

Lower Palaeolithic Remains.—In lower palaeolithic times this area was an outpost of the cultural province termed pre-Mousterian, where men of the Neanderthal species have left their flake implements. An early ancestor of that species is apparently represented by the celebrated jaw found at Mauer (near Heidelberg) belonging to the Mindel-Riss' interglacial, while true Neanderthalers are found at Krapina in Croatia during the next warm phase. Only near Arad are there any traces of an industry comparable to the western Chellean, and these are doubtful. But towards the end of the lower palaeolithic age rather small hand-axes of Acheulean affinities attest influences from the west and perhaps also from the south, especially in Lower Austria, Galicia and South-west Germany. These types persist, in company with typical Mousterian, throughout the middle palaeolithic term.

Upper Palaeolithic: Předmost.—Then, after the crisis of the Würm glaciation, mammoth hunters of neanthropic type pitched their camps on the löss at Předmost, Vistonice and Willendorf and must have followed the tracks that the great pachyderms must follow as they passed to and from the Eurasiatic plain through the Moravian gates. The flint work here is reminiscent of upper Aurignacian but shows Solutrean "influence" at Předmost. On the other hand, these hunters employed great clubs and perhaps even hafted axes of mammoth bone and ivory, unknown to the west. They carved female figures, similar to those from contemporary deposits in France and Italy, and models of their prey in ivory and even moulded clay figurines which they allowed to harden by their hearths. Their decorative art, on the other hand, was extremely abstract in contrast to the naturalism of the west. At Předmost the remains of the departed, ceremonially buried in a collective tomb fenced about by mammoth bones, seem to belong to two physical types, one of which is thought by some to exhibit Neanderthaloid affinities.

Proto-Solutrean.—Side by side with the Předmost culture there flourished another south of the Slovakian mountains, from which the Solutrean of western Europe is sprung. Its earlier tools are often Mousterian in form, but have been worked on both faces by the pressure flaking that characterizes the French Solutrean. The authors of this culture, derived apparently from a local Mousterian, in a later stage of their development influenced Předmost and eventually spread westward, perhaps to escape the cold of the Bühl advance, bringing with them the classical Solutrean culture which on French soil developed to a stage that is scarcely represented in Central Europe.

Survival of Hunters.—Both the men of Předmost and the proto-Solutreans disappeared, leaving but few descendants to hunt the reindeer. In Bavaria, Bohemia and Galicia these were more or less affected by the Magdalenian culture of France, though their civilization shows certain peculiarities. And then, as the forests began to spread with the return of milder climatic conditions, some of these in turn migrated northward with the reindeer, taking to Denmark the so-called Lingby culture, while scattered bands, isolated by the primeval forests in caves or on sand-dunes in Bavaria, Thuringia, Poland and North Hungary, carried on the old traditions in an epipalaeolithic microlithic industry.

Neolithic Cultures: Danubian.—Meanwhile the neolithic culture was blossoming forth as something quite new on the open löss plains of Lower Austria, Moravia and Silesia. Its authors, who may be termed Danubians, were peasants, not hunters. As their principal crop they raised the small "Einkorn" wheat (*Triticum monococcum*), tilling small plots with stone-bladed hoes. Owing to their primitive methods of "garden culture" the Danubians made no permanent settlements, but squatted for a few years in half-subterranean huts, to move on again as soon as the soil showed signs of exhaustion. In this way they spread into Bohemia, Thuringia and Bavaria, and eventually, when drier climatic conditions had brought about a thinning out of the forest, on to the löss lands of the Rhine valley, Belgium and North France.

The Danubians' typical tool was a polished stone adze or hoe, flat on one face and arched on the other, and a chisel of the same form; both are termed "shoe-last celts." Bone and flint were very sparingly used. The sole weapon was a disc-shaped stone mace-head, with precursors at Předmost and in pre-dynastic Egypt. Fine pots were manufactured in a grey ware, the commonest forms being a hemispherical bowl and a globular bottle, both seemingly imitations of gourds.

The Danubians decorated their pots and bone objects in a free geometric style with spirals and maeanders, the latter being a motive familiar to the hunters of the Předmost culture. The Danubians also made female figurines of clay as had their palaeolithic forerunners. Early graves are scarcely known, and certain finds in Bavaria suggest that the Danubians had burned their dead. But later on inhumation in the contracted position was regularly practised. In such graves ornaments made from a Mediterranean shell, *Spondylus gaederopi*, are often found.

Vinča.—South of the marshy regions of Central Hungary an allied but far richer culture was growing up that is best studied at Vinča, just below Belgrade. Here the settlements were of a more permanent character, and the presence of copper beads suggests some sort of intercourse with the Eastern Mediterranean. The implements agree with those described further north, but the pottery, though obviously akin to the northern Danubian, is far more varied. *Spondylus* ornaments occur as in Moravia. It is possible that the Danubian culture is just a degenerate offspring of that of Vinča. Or perhaps both are separate branches of an older culture that had used gourds instead of pots. In any case the roots of both civilizations lie in the east Mediterranean region, though a survival of Předmost traditions can hardly be denied.

The simple Danubian of the north gave birth to various local cultures which may be due to epipalaeolithic hunters mixing with the peasants who were invading their territories. Meanwhile the civilization of Vinča spread into Istria, Bosnia, and perhaps along the Morava-Vardar corridor into Macedonia and North Greece.

Lengyel Culture.—Before 2,500 B.C. a third group termed the Lengyel culture had emerged on the Upper Tisza and quickly spread as far as Silesia, Thuringia, and Bavaria in the wake of the Danubians, while it profoundly influenced its southern neighbours. The new folk dwelt in regular villages and combined farming with trade and war. While their tools were mostly of Danubian type, they enriched their armoury with obsidian knives, arrows, spheroid mace-heads and hammer-axes, and imported copper in addition to sea shells for trinkets. The vases, no longer mere copies of non-ceramic vessels, include composite forms, notably a dish on a high hollow foot, and vases with necks. Some mugs are provided with two handles suggesting the influence of Trojan metal-work.

Art now demanded expression in colour, and so the vases were decorated with red, yellow and white earth-paints, daubed thickly on the black surface to form spirals and other patterns. Clay figures of women and animals and miniature vases were also manufactured. The dead were normally interred in the contracted position in regular cemeteries like the later Danubians, or, much more rarely, cremated.

The Lengyel culture is essentially Danubian, albeit profoundly influenced by Anatolia and perhaps also by steppe-folk from the east. Still relations in all these directions were bilateral. Lengyel influence is certainly detectable in Thessaly and perhaps in Troy, and on one theory extended eastward to the Dnieper.

Painted Pottery.—In eastern Hungary high-footed dishes of Lengyel form were sometimes adorned with rectilinear patterns painted in a *fast* brown on a buff slip. Then on the Upper Alt in Transylvania these and other types of vases are found beautifully painted with polychrome spirals and maeanders at 26 sites, of which Erösd is the most celebrated. Rather similar material has been found in the oldest settlement on the hill of Cucuteni near Jassy, in Moldavia, and then in the Kiev Government, in settlements of the "Tripolye A" group where, however, incised ware is far commoner than painted. All these eastern vase-painters lived as farmers in regular villages, which at Erösd and Cucuteni were fortified. At Erösd the houses were quite substantial gabled structures of wattle and daub with a porched entry on the short side. The Tripolye sites are characterized by "areas" of burnt clay—presumably the ruins of huts destroyed by fire—but said by Russian archaeologists to represent cremation necropoleis. The villagers were acquainted with copper, which they used for ornaments and even axe-heads, but were losing the art of working stone except for battle-axes, long knives and arrow-heads. Clay models of men, animals and huts and miniature vases everywhere accompany the painted pottery. Some hold that these allied cultures are just an eastern extension of that of Lengyel, enriched by cultural borrowings from Thessaly or Hither Asia. Others, on the contrary, contend that the cultures in question are of oriental origin (camel bones were actually found at Tripolye) and spread westward across the Ukraine to the Danube valley, where their reaction on the Danubian substratum produced the Lengyel culture. It is at least certain that these cultures are not of southern origin. On the contrary, people allied by pottery and architecture to the inhabitants of Erösd reached eastern Thessaly (Dimini) and even Corinthia as intruders.

In Transylvania Erösd had no direct successor, but at Cucuteni and in the Ukraine the older culture, characterized by polychrome painting and spiral motives, grew into another, distinguished by light coloured pots adorned by disintegration products—circles etc.—in black paint on a buff ground. With the latter, which otherwise carries on the older traditions, middle Helladic pottery imported from Greece has been found at Cucuteni, so that the later settlements were still inhabited after 1800 B.C. A very specialized branch of the same stock found in Thrace (Wallachia and Bulgaria) seems in places at least to have lasted into the iron age, though no tools or weapons of the types current in the bronze age further west occur in the area.

Pastoralist Intrusions.—In the Danube valley we find that with the closing years of the third millennium the forest barriers to the north and east were breaking down completely; for the climate was growing drier and warmer than to-day, and the woods were thinning out. And so Central Europe was exposed to the incursions of warlike tribes of pastoralists and hunters and the so-called "Nordics." They introduced the oldest sheep-dog (*Canis familiaris matris optimae*), and perhaps the horse, as well as new grains, including emmer. They used flint celts or rectangular stone celts with squared small sides, stone battle-axes, flint arrow-heads, and a variety of tools of bone and horn. Rare amber beads reveal the first relations with the Baltic area, while copper objects, including awls and axe-heads, and Mediterranean shells denote continued intercourse with the south.

A first result of such incursions was the emergence of hybrid groups, largely Danubian, as the technique of the pottery shows, while its forms, influenced by vessels of leather or basketry, no less clearly betray the superposition of the pastoralist element from without. Furthermore, there was one compact body of semi-nomadic folk with a centre in Thuringia who ranged from the Volga to the Rhine and from the Upper Tisza to Finland. They were armed with great battle-axes of stone, reared a barrow over their graves (in which the dead were buried in the contracted position) and ornamented their vases—beakers and amphorae—with cord-impressions. In Hungary the incursions have left less mark, unless the curious copper axes with one blade parallel and the other at right angles to the shaft be the counterparts of the stone battle-axes used further north, where no copper was available. In eastern Hungary there are also barrows covering contracted skeletons stained with red ochre as in South Russia.

Lake-dwellings.—The invading tribes may have come from Scandinavia or from South Russia, or they may, in part at least, have been descendants of the epipalaeolithic hunters living on the sand-dunes of Poland and Thuringia. In the Alpine regions and along the Rhine such survivors of the old stone age had certainly evolved a civilization of their own, though its constituents were largely borrowed from the Danubians, and perhaps partly from cultural centres on the western Mediterranean and Atlantic coasts. On the Swiss lakes small hamlets were built, strung out along the margin of the lake, the rectangular wooden houses being raised on piles above the sedgy shores (the lake-waters had already sunk below the present level). Further north kindred people were occupying the hills overlooking the Rhine and defending them with wide, flat-bottomed moats, banks and palisades. Here the type site is the Michelsberg north of Carlsruhe. Lake-dwellers and Michelsberg folk alike were farmers possessed of flocks and herds and cultivating grains, flax, and perhaps even fruit-trees. They excelled in basketry and horn-work; the stone axe-heads were often hafted with the aid of horn sleeves to diminish the shock of the blow by the elasticity of the horn. The pottery, in technique very like Lengyel ware, is based upon leather forms and devoid of ornament.

In the Eastern Alps, in Carniola, near the mouth of the Drave in Slavonia and in Bosnia settlements akin to those just described occur, but they show here an infusion of "Nordic" elements—*e.g.*, stone battle-axes—while the pottery is decorated with patterns suggestive of Cypriote influence, though they are executed in a technique that must have been borrowed from the wood-carver.

South-Eastern Trade.—All this time the current from the south-east detectable already in the Lengyel culture had been flowing up the Danube. Eventually it culminated in the foundation of new settlements on the auriferous streams flowing out of Transylvania and on the approaches to the Slovakian copper lodes; the best known is at Tószeg near Szolnok. In the new settlements, though Lengyel forms occasionally appear, the pottery in technique and form is dominated by Anatolian traditions. Stone axe-heads are rare in the settlements, whereas in them and in contemporary graves copper or bronze torques with looped ends as in North Syria and the Caucasus, wire pins with a knot head as in Cyprus and at Hissarlik, and gold ear-rings of Mesopotamian-Trojan type, are to be found. Daggers with long hooked tangs, imported from Cyprus, have turned up stray or in hoards in the same region. Similar Anatolian bronzes and pot-forms are found as far north as Bohemia. Everything points to the conclusion that Anatolians or Aegeans were by now collecting gold on the Maros and Aranka, exploiting the copper-lodes of Slovakia and washing for tin in the streams that flowed over the Bohemian löss from the stanniferous Erzgebirge. The beginning of tin-working in Bohemia is perhaps dated by the appearance of rich bronze at Troy and in North Syria at the opening of the second millennium.

Beaker Folk.—About the same time a new element, the so-called Beaker-folk, appeared on the scene from the west, crossing the Alps by the Brenner and visiting Bavaria, the Rhineland, Bohemia, Thuringia, Silesia, Moravia and the district round Budapest. In their graves—settlements are unknown—short-headed skeletons were buried in the contracted position accompanied by fine, well-shaped beakers, flint arrow-heads, stone wrist-guards, copper awls, small tanged daggers, conical buttons with V-perforations, and trinkets of gold all very much as in Spain, South France, Brittany, Sardinia and North Italy. Between the Elbe and the Rhine the Beaker-folk combined forces with the warlike nomads who buried their dead under barrows with cord-ornamented pottery. The fusion is symbolized by a beaker of inferior technique and slender form that is found under barrows as well as in flat graves. People of the mixed stock descended the Rhine and crossed to Britain soon after 2000 B.C. Though beakers are found at some 80 sites in Moravia and at 70 in Bohemia, their makers never settled down there in any numbers. They had made incursions as armed traders, but disappear as a physical type from Central Europe. Still they had established communication between the Mediterranean and Bohemia via the Adriatic and the Brenner, while Bohemia was in turn linked with the amber deposits of Jutland and the copper lodes of Slovakia. The commercial connections that are preconditions of the rise of a bronze industry were thus established, and simultaneously with the fall of Troy II. about 1800 B.C. the Anatolian metallurgists who had discovered Bohemian tin and Slovakian copper were forced to begin producing for a local market.

Early Bronze Age: Aunjetitz Culture.—Almost immediately after the Bell-beaker episode begin the extensive cemeteries of the Aunjetitz culture (so called after Únětice, south of Prague), spread out along the amber trade-routes, leading from Upper Italy to Denmark and East Prussia across Bavaria and Thuringia or Silesia, and along those connecting the Bohemian tin district with Slovakian copper, but concentrated especially in Bohemia. Long-headed people are buried in them accompanied by round-heeled, riveted daggers, flat and flanged celts, and various pins, bracelets and torques all of true bronze. Amber is common in the graves, and gold is far from rare. The pottery is largely developed out of the "Anatolian" series that spread up across Hungary modified by "Nordic" and Bell-beaker traditions. The development of the older culture at Tószeg and other Hungarian sites led to very similar shapes, and in the second strata we find daggers and pins that agree on the whole with those from Aunjetitz graves. But the focus of that culture was Bohemia, and the parallel cultures of Hungary were relatively poor. Yet Tószeg was at this time defended by a palisade of stout posts, and some of the houses may also have stood on piles.

Tumulus Bronze Culture.—The Aunjetitz folk were peasants, traders and industrialists living in the fertile valleys. While their life was proceeding uneventfully from 1800 to 1500 B.C. (for Minoan metal vessels of the latter age were imported and imitated locally), the pastoral tribes who had occupied the hill country of south-west Germany and western Bohemia were slowly learning the art of metallurgy. Like their neolithic ancestors they heaped barrows over their graves and are accordingly known as the Tumulus folk. The graves are sometimes richly furnished with weapons and ornaments: ogival knife-daggers with bone or wood handles fastened to the blade by large rivets, swords of the same type or with solid bronze hilts, sometimes 70cm. long, socketed spear-heads and very slender axe-heads with flanged sides or medial wings or, in Bohemia, with a V-shaped stop-ridge, and round shields of wood or leather strengthened by bronze bosses, which alone survive. Men and women alike wore pins with an eyelet in the swollen neck or terminating in a wheel, penannular bracelets and finger-rings terminating in opposing spirals of bronze ribbon, anklets, again with spiral ends, and pendants hung on the necklace or the girdle. Amber was imported from the Baltic and glass beads from the eastern Mediterranean.

The foregoing types characterize the middle bronze age of south-west Germany and Bohemia, which lasted from 1600 to 1300 B.C. Before its end a rapier of late Mycenaean type had found its way to Bavaria, and heavy slashing swords, often with an octagonal bronze hilt, were coming into use among the Tumulus folk. Their culture lasted on throughout the late bronze age till, with a return of a damp, cold climate about 800 B.C. it becomes transformed, through contact with intruders from Illyria into a Hallstatt culture. In the late bronze age barrows cremation became the commonest funerary rite under the influence of the urnfield folk, the swords were heavy and leaf-shaped and the pins grew to extravagant lengths. Barrows of this period are found also south of the Alps in north-west Hungary, Styria and Bosnia. In the last-named area inhumation was the regular rite and early forms of safety pin were in use. They were little more than pins bent round for security with the point caught against the head.

Hungarian Bronze Age.—In Hungarian settlements which, like Tószeg, were occupied continuously throughout the bronze age, the beginning of the middle phase is marked by a layer poor in ceramic remains that may denote a partial evacuation of the site. The foundation of the *terremare* in the Po valley about the same time may be the counterpart of this partial break. Nevertheless the Hungarian plain was by no means deserted, since numerous and splendid bronzes (dated by their occurrence in middle bronze age hoards in the north) were being cast in this period. Most distinctive are battle-axes, some with a knobbed butt-end and others with but one blade, that recall Asiatic types. They are often gloriously decorated with scroll patterns. Such Hungarian bronzes were exported to Bavaria, Mecklenburg and the Ukraine.

Eventually the whole plain is found to be covered with urnfields, *i.e.*, cemeteries of urns containing cremated bones. The urns and accessory vases were often beautifully decorated, in the west with excised patterns, in the south with punctured lines and stamped circles and in the north with conical warts. In the southern graves models of female personages were sometimes deposited, as at Kličevac in North Serbia. The people buried in these cemeteries must have belonged to a mixed race of farmers, traders and metallurgists.

Lausitz Urnfields.—Similar communities appear about the same time in Moravia, Bohemia and Silesia, but especially in Lausitz, whence these are termed the Lausitz people. They were the economic heirs, and probably the descendants, of the Aunjetitz people of east-Central Europe though they cremated their dead, burying the remains in large urnfields. Their houses were built on the log-cabin principle and formed regular villages. The Lausitz folk were the first people in Europe to adopt the socketed celt, and sometimes they used safety pins (*fibulae*) for fastening their clothes. The Lausitz pottery was ornamented at first with big conical worts like the contemporary ware of northern Hungary, and later with corrugations. The typical ossuary, shaped like two cones placed base to base, was usually perforated with a hole to allow the ghost to escape.

The Lausitz people spread very widely, over-running Lower

Austria, Slovakia and North Hungary and apparently even reaching Macedonia about 1050 B.C. Another branch spread westward towards the North Alpine zone—Bavaria and the Tyrol—where extensive urnfields with occasional Lausitz ossuaries mixed with other types appear in the late bronze age. But the North Alpine urnfield culture is complicated owing to the absorption in it of western Aunjetitz people and Alpines and to its relations, both peaceful and hostile, with the Tumulus folk of the same area. Hence the North Alpine culture has a martial aspect, the graves being furnished with heavy swords and other weapons. Yet the people buried in them were pre-eminently industrialists; it was they who inaugurated the systematic exploitation of the Alpine deposits of copper and salt by shafts and tunnels that are traceable to-day. The same people conquered Switzerland, where they synoicized the hamlets beside each lake into one or two larger pile villages. The latter became flourishing industrial centres whose products—swords, knives, penannular razors and ornaments—were exported in all directions. In exchange there came amber, bronze basins and *fibulae* from Denmark, copper, tin and antimony from the east, and Villanovan artifacts from Upper Italy. Another branch of the same stock had spread down the Rhine valley to Holland, whence they eventually reached England.

The Coming of Iron.—Just south of the Alps in Styria and Illyria there were other urnfields, existing side by side with tumulus groups, whose authors may have included Hungarian and Lausitz elements. In this area, traversed by the trade routes that led from Upper Italy to the copper and antimony mines of Hungary and the Alps and eventually to the amber of East Prussia, the use of iron, transmitted up the Adriatic, was early adopted, as was that of the safety-pin. Before 1000 B.C. we meet here the prototypes of the slashing leaf-shaped swords and the various safety-pins, especially the spectacle brooch, that later characterized the "Hallstatt" culture. So we infer that the civilization, named after the prehistoric village of salt-miners at Hallstatt in Upper Austria, was moulded along the eastern slopes of the Julian Alps, whence the knowledge of iron was spread along the main trade-routes among the urnfield-folk of Austria, Moravia and Silesia.

In Slovakia and North Hungary, on the other hand, which since 1100 B.C. had been under the control of Lausitz people engaged in exploiting the rich deposits of copper, a brilliant but belated bronze age civilization was elaborated while the use of iron was beginning further west. In the enormous hoards of this period we meet not only socketed celts, beautifully decorated leaf-shaped swords and very complicated brooches, but also great bronze buckets and bronze or gold cups, ornamented with embossed patterns such as birds' heads flanking a disc, identical with those current in Villanovan Italy. Farther to the south-east remnants of the native population, having survived the shock of the Lausitz invasion, continued in a bronze age, as, farther north, till the 8th century B.C., rejecting not only iron but such innovations as the safety-pin and the socketed celt that their neighbours had appropriated.

By 900 B.C. the Tumulus-builders living south of the Noric Alps had adopted from their neighbours, the urnfield-folk of Styria, the use of iron and the types of safety-pin and sword that the latter had elaborated. Some of the Tumulus folk, notably those congregated on the high plateau of Glasinac in South Bosnia, were also in contact with the Greek world. From these western highlands inhumationists spread eastward into the upper Morava valley and thence to Macedonia and Bulgaria, taking with them the spectacle brooch and other types of Styrian antecedents. Other bands spread along a parallel route across western Hungary and then up the Maros, while, very probably, a similar movement in a more northerly direction brought the classical Hallstatt culture to Moravia and Silesia on the one hand and to south-west Germany on the other. In these regions the presence of Illyrian intruders among the urnfield-folk is revealed by inhumation burials furnished with horse-trappings and Hallstatt swords and safety-pins. But the intruders were far from numerous and mingled with the urnfield folk and the older Tumulus-builders.

Then between the 7th and 5th centuries Silesia and still more Transylvania and northern Hungary were raided by Scyths from the east, while abundant Scythian products were introduced in exchange for copper and antimony. The regular use of iron in Hungary and Transylvania was due to these incursions. Down to the 4th century the lowlands east of the Danube were dominated by the eastern power, while further west the later Glasinac and Hallstatt cultures developed under Italian influence. After 400 B.C., however, La Tène forms and the use of the wheel began to percolate eastward, in some cases at least brought by Celtic invaders. Their infiltrations form a prelude to more extensive incursions, as a result of which the culture of Illyria and Pannonia was assimilated to that of the Celtic west before the Romans occupied those provinces. (*See* Hallstatt, *La Tène*, *Villanovans*.) (V. G. C.)

RACES AND PEOPLES

Pigmentation of skin, hair and eyes, diminishes in Europe from the Mediterranean northwards to mid-Norway and Sweden, to increase again in the Arctic. Stature increases from the Mediterranean northwards to mid-Norway and Sweden, to diminish again in the Arctic, but the changes are less regular for the Dinaric peoples, and the Castilian Spaniards are mostly tall. The Iberian peninsula, Sardinia, Corsica, Sicily, south Italy, have long-headed populations and so have various areas in France, the British Isles and Norway and Sweden, apart from the Arctic area, in which the head runs very broad. The great mass of peoples of central Europe, from central France eastward to central Russia, and from Greece and north Italy to Prussia is broad-headed though less pronouncedly so in the north.

Main Divisions.—Ripley and Deniker have made schemes to express the above facts. A *Teutonic* or *Nordic* race, with tall stature, bony frame, light colouring and a fairly narrow head is described chiefly for Norway, Sweden and parts of Finland, Denmark, north-west Germany and Britain. A *Mediterranean* race is described chiefly for the western basin of that sea, with short stature, relatively slight build, dark colouring and a narrow head; and an *Alpine* race inhabiting central Europe as above mentioned is described as broad-headed with broad face, thick-set frame, brown hair and grey to brown eyes, the colouring being darker in the south. The majority of the British people would be somewhere between the Nordic and the Mediterranean, and would include representatives of both.

Deniker added an Adriatic or Dinaric variant of the Alpine race, with tall stature, and a high head, found chiefly in the west of the Balkan peninsula and in Venetia, with congeners from Asia Minor and Armenia. The more ordinary short Alpine round head he called "Cevenole" or "Occidental." The rather broad-headed fair types of the regions north-east of central Europe he called the Oriental race; much the same group being termed by others the East-Baltic race. He also gave the name Atlanto-Mediterranean to an element with taller stature and less narrow heads among the people of the Iberian peninsula.

Origins of the European Types.—The origins of these types are a difficult problem. Myres has suggested the spread of broad-headed peoples from Asia Minor and, since it has been shown that peasantry spread into Europe largely through the Danube basin, it has become increasingly probable that the Alpine race is closely linked with this spread, and that its Occidental or Cevenole branch is an earlier arrival that has spread farther. In Galicia and the Ukraine, etc., are found both taller and shorter varieties, and it is thus probable that both have spread into Russia. The extension of broad-headedness northward and north-eastward is a

marked feature, and is probably connected with a biological dominance of broad-headedness over long-headedness; the extension is marked by increasing fairness of colour. Tall, broad-headed men with strong supraorbital sinuses and prominent brows are a marked feature of the European plain from Polish Galicia to England, and they are usually fair in colouring. Their skull type is much the same as that found in burials of the early ages of metal, with accompaniments of Beaker pottery, and so this type has been called the "Beaker" type.

As to origins of the long-headed types in Europe, most of the Upper Palaeolithic skulls are dolichocephalic, and in that early period there were streams of people, with long heads, from north Africa, as well as, probably at a later stage, from the south Russian steppe. Here and there, as in Tras os Montes (Portugal), Sardinia, La Dordogne (France), Plinlymon (Wales), inland Norway and mid-north-Sweden, there are groups of people with the very long, very high and narrow heads, strong brows, big cheek bones and rather broad noses of certain Upper Palaeolithic skulls. It is, therefore, likely that survivals from the Upper Palaeolithic age are one element in the composition of the European peoples. Ripley was inclined to think, and many agree, that in the cool, cloudy north-west, the type became taller through postponement of maturity, and fairer; the warmth of the south, on the other hand, encouraging the maintenance of pigment and of relatively early maturity. The localized distribution of survivals of ancient types suggests that they are not merely the extreme cases in a large group of variants, their likeness to early skulls (especially Combe Capelle and Předmost skulls) supports the view that they are survivals. It has also been claimed, with less strength, that there are survivals of other Upper Palaeolithic types such as that of Grimaldi (lower layers) and that of Cromagnon.

Arctic Europe has received westward drifts from Asia of dark-skinned dark-haired broad-heads, and there have been spreads of Asiatic broad-heads into the south Russian steppe and into east-central Russia.

Giuffrida-Ruggeri, Biasutti, Collignon, Pittard, Beddoe, Arbo, Bryn and Fleure have noted at various coastal spots from south Italy round to Norway, dark broad-heads, often tall, who seem to be the origin of Deniker's idea of the Atlanto-Mediterranean type, a type which he derived from statistics of populations that included both these broad-heads and the Mediterranean type. Many of the broad-heads of north Brittany belong to this powerful type rather than to the Alpine type as commonly stated.

It seems not improbable that broad-headedness in Europe acts to some extent as a Mendelian dominant (*see* HEREDITY), and probably, in some crosses at least, brown eyes are dominant over blue ones. Thus types may appear to change in the course of time without there being vast migrations to account for this.

Thus almost every country has a people of mixed breeds. Italy has chiefly Mediterraneans in the south and chiefly Occidental Alpines and Alpine-Dinarics in the north. Germany is mainly Alpine, with marked fairness of colour and some Nordic long-headedness near the Baltic, and here and there in other parts. France is mainly Alpine, but of darker colouring than Germany, with some Mediterraneans in the south and west, and some Nordics in the north and east and many mixtures. Britain is long-headed, with a good many Nordic types in the east, and Mediterranean types in the west and south-west, and vestiges of the curious type noted above for Castile in Devon, Wales and the west Scottish Highlands. But the great mass is neither fully Mediterranean nor fully Nordic, thus lending support to the idea that each of these is the result of evolution in its characteristic area, Britain being between the two.

Terms Used for Races.—It may be useful to add notes on various terms the names of which are often used in racial discussions.

The *Basques* are a linguistic and social rather than a racial group, though they are mostly long-headed and very probably include survivals of Upper Palaeolithic types. They occupy the western Pyrenees on the French and Spanish sides, and the language has a considerable extension south-westward on the Spanish flank. The Basque language (*q.v.*) does not belong to the Indo-European language family at all, and is probably very ancient. The people have many social features, such as house-types, ceremonies, games, etc., distinguishing them from their neighbours. They still call themselves *Eskualdunak, i.e.,* "those who possess the *Eskualda*" or Basque tongue.

The name *Aryan* (*see* INDO-EUROPEANS) has been used in many senses at different times. It was once supposed to relate to a people of central Asia who were supposed to have drifted west into Europe, bringing our civilization with them. It is strictly used for an element in a language-group, the two most primitive survivals of the group being Sanskrit and Lithuanian. It has recently been argued on archaeological grounds that the Aryan languages probably developed on the steppes of south Russia, and were spread thence in the 3rd and 2nd millennia B.C. by long-headed warriors armed at first with perforated stone battle axes, and later with bronze.

The name *Celtic* has been used, especially in France, to name the Alpine broad-heads so characteristic of the region that the Romans called Gallia Celtica. It is strictly used for a language group (*see* CELTIC LANGUAGES) and is best discarded as a racial name. The peoples of Celtic speech in modern Europe include a considerable proportion of individuals of dark, short, long-headed type (Mediterranean race).

In the Balkan peninsula race, language, religion and economic life are all important as dividing features among the peoples. The western mountains contain many of the people called Dinaric, the ordinary short round-headed Alpine stock is characteristic for the Serbian Morava basin and for the Rumanian peasantry, as well as among the Bulgars. The last owe their name, some features of their language, and occasional physical characteristics to Asiatic (Tatar) elements entering from the south Russian steppe. The Rumanian peasantry, largely Alpini, includes also some dark long-headed elements, especially, it is said, in the north-east. The name of Vlăchs, people of Wallachia, is applied also to nomad groups, who in generations past have wandered between Thessaly and the Danube and in Transylvania. The Rumanian language, as is usual for any European region that felt the Roman power, owes a great deal to Latin. In the west the Albanians form a warlike highland group organized in clans, with blood feuds between them; they are largely Dinaric in type, but apparently include some fair broad-heads who may be descendants of immigrant conquerors of early times. The coastal Greek population appears to be predominantly broad-headed on the mainland, with long-headed elements chiefly in the islands.

The Lithuanians and Letts are the best known peoples of the forested basins of the Niemen and Duna, mainly rural, with German elements in the ports and Jewish elements in the towns generally. It has been said that the Lithuanian language (*q.v.*) is an early member of the Aryan family; the Lett language (*q.v.*) includes Slavonic elements and is said to preserve features from the non-Indo-European tongues of the region. Both language groups include many fair, broad-headed types with some Nords.

The Finns and Goths speak languages with north Asiatic affinities, but should apparently not be confounded with the Lapps and Samoyedes on this account. They include a Nordic element of Swedish origin, the fair broad-headed element usually described as "East Baltic," and doubtless in the remoter parts a considerable Arctic (Lapp) element. The Tavastlandian Finn has been supposed to be longer and the Karelian or Eastern Finn broader-headed.

The Magyars speak a language of the Finno-Ugrian family (*see* HUNGARIAN LANGUAGE) brought in by conquerors who came westward via south Russia after the decline of the Roman power. Asiatic elements are not physically conspicuous among them save among gipsies, who are fairly numerous on the Hungarian plains, and it is supposed that those elements have diminished and disappeared in the course of subsequent centuries. (H. J. F.)

HISTORY

The history of Europe can only be written in so far as it is possible to consider the European peoples as a whole. The task

of history, therefore, is to show how the unity of Europe was effected. This resulted from several causes: first, from the common customs of everyday life, religion, and law; secondly, from the general similarity of social and political organization; thirdly, from the subjection of different peoples to a single political or religious authority; fourthly, from the establishment of permanent relationships between the different European States. The solidarity of Europe has only been achieved very slowly as from time to time new peoples have come under the influence of European civilization. In this sense Europe has continued to expand throughout the centuries. Beginning in the extreme south-east, in the days of the Roman empire her civilization spread over the Mediterranean sea-board and to the coasts of the Atlantic. During the middle ages it advanced over central Europe and the Scandinavian countries. Russia entered the comity of Europe only at the beginning of the 18th century, and it was not until the 19th century that the conception of European unity was expressed in the language of diplomacy by the use of the word "European."

THE FOUNDATIONS OF EUROPEAN UNITY

The People.—Since prehistoric days the inhabitants of Europe have belonged to the same white race, whose branches are also to be found in western Asia and northern Africa. Anthropologists, in classifying the population of Europe according to anatomical characteristics, have distinguished three principal types living in three distinct zones: in southern Europe on the coasts of the Mediterranean, the Mediterranean type with very dark skin, black eyes and hair, and long heads (dolichocephalous); in central Europe the Alpine type with light brown skin, brown hair and eyes, and round heads (brachycephalous); and in northern Europe the tall Nordic type with white skin, golden hair, blue eyes and long heads. The peoples of Europe are essentially the products of the long cross breeding of these types; they show a mixture of the characteristics of each type, and individuals of a single pure type are rarely found except in small isolated groups. This mingling of characteristics remains the most typical characteristic of the European population. *See* RACES OF MANKIND.

From prehistoric days this people has possessed a common primitive civilization which, in its origin, goes back to the Neolithic age. Its principal occupation was the cultivation of crops and the raising of cattle; its cattle were used in the processes of cultivation, and their manure was used upon the fields. These primitive peoples grew wheat, rye and barley which have remained the staple foodstuffs in Europe until the end of the 19th century; their domestic animals—cows, sheep, pigs and goats—were the same as those of modern times.

The languages spoken throughout Europe, with the exception of Basque, are all derived from a mother-tongue (called by philologists Indo-European). This language can accurately be called European, for the Aryan languages outside this region, such as Iranian in Persia and the Indian Sanskrit, were those of peoples who passed from Europe into Asia.

Throughout Europe political organization developed along similar lines. The tribes were divided into small independent communities, each of which acknowledged the authority of warrior chiefs, whose office was nearly always hereditary but who were possessed of scanty material resources. No single chief was powerful enough to make his authority run throughout a wide territory, nor to compel his subjects to render to him the servile obedience shown to an oriental despot. Until the days of the Roman empire no great autocratic monarchy arose in Europe, but while maintaining the independence of their local sovereignties, the European peoples preserved also a sense of unity among themselves and an interest in public affairs at a time when the Governments of the autocratic empires had destroyed the sentiments among the peoples of the East.

The possession of a common racial and linguistic origin and of similar customs and political institutions, created in the European races certain common characteristics which facilitated the attainment of European unity. Not that the peoples could be alive to these profound affinities; as yet they showed no sense of brotherhood or solidarity. Each man saw an enemy in his nearest neighbour; war was a normal condition, not only between groups that differed one from another in customs and language (as for example, the Greeks, Thracians, Latins, Samnites, Gauls and Germans) but also, and even more frequently, between little neighbouring tribes who were conscious of a common origin like the Spartans and Athenians, the Romans and the Albans, the Aedui and the Arverni.

The European peoples were brought together voluntarily by commerce and the spread of science and art, forcibly by military conquest and by the barbarian invasions. The unity of Europe had been prepared between the 5th century B.C. and the 8th century A.D. by three great events: the diffusion of Greek culture throughout the Mediterranean sea-board; the establishment of the Roman domination, first in the Roman empire and, later, in the Roman Church; and the invasion of the Germanic barbarians, which destroyed the social and political organization of the empire.

Greek Civilization.—Greek civilization, preceded from the 18th to the 15th century B.C. by the Aegean civilization, was established between the 6th and 4th century B.C. in the Greek cities as a result of the reaction of the Greek intellect on the material culture or the old civilizations of Egypt and Asia. It reached its widest extent from the 3rd to the 1st century B.C. in the Hellenized kingdoms founded by the successors of Alexander the Great. It was this later civilization known as Hellenism, and not the pure Greek civilization, that gradually spread over the Roman empire and hence throughout Europe. It was, above all, of an intellectual character and it was in the spheres of art and science that it left its most permanent traces upon European civilization. For example, in all European languages, as spoken in the 20th century, words derived from the Greek are still used for many forms of art—music, poetry, lyric, epic, tragedy, comedy, drama, theatre; while the same is true of scientific terms—mathematics, arithmetic, geometry, mechanics, astronomy, physics, optics, chemistry, biology, botany, geology, philosophy, rhetoric, grammar; and also of mental science—method, logic, dialectic, critic, empiric, autopsy. The whole of modern science is permeated with the Hellenic spirit—the spirit of reason, observation and criticism, and free from the trammels of religious mysticism and tradition, which have killed the intellectual life of other peoples.

The Roman Empire.—Having conquered the Mediterranean peoples and those on the shores of the Atlantic, the Romans subjected them to a permanent domination known by the significant term *Imperium* (military authority). The Roman empire in the 2nd century A.D. extended throughout northern Africa and western Asia, and in Europe over all the Mediterranean countries, and over Spain, France and southern Britain. Throughout its immense extent inter-tribal warfare was stopped and the *pax romana* established, while, as a defence against the still barbarian peoples, it maintained permanent garrisons along the entire length of its frontiers, marked in Europe by the Rhine and the Danube. It is true that the greater part of Europe remained outside the empire, but this external region was only thinly populated by barbarian tribes—Scotland, Ireland, Germany, Scandinavia, Austria and Russia. The whole civilized and settled part of Europe was united under a unique authority, which lasted for three centuries, and accustomed the whole population to a single political and social organization. The empire, although becoming little by little an autocratic centralized monarchy, yet left a large local autonomy to the cities that were governed after the Roman model by a local aristocracy of landed proprietors. But the continuous action of the central power, exercised by his delegates in the name of the emperor, ended by bringing the whole of Europe within the same economic, political and legal civilization which, under the name of Roman, was an international conflation of the customs and ideas of all the peoples of antiquity.

Roman Civilization.—Roman civilization survived the empire and became a common European possession. It survived in the Latin language, which in its vulgar form gave birth to all the Romance languages (Italian, Provençal, French, Portuguese, Castilian, Catalan, Rumanian) and in its literary form survived until the 17th century as the common intellectual tongue of

Europe. It survived in political terminology where words of Latin origin are still used (suffrage, scrutiny, vote). It survived in the language of building construction—mortar, arch, door, bridge, road (strata), castle (castellum). It further endowed Europe with a system of weights and measures and a currency based on the combined employment of gold and silver, and it gave her a calendar, oriental in origin but reformed by Caesar, and hence known as the Julian calendar, containing the names of the 12 months and the seven days of the week, which in the Romance lands still preserves the memory of the Roman gods, Mars, Mercury, Jupiter, Venus and Saturn, for some of which were substituted in the Teutonic countries the names of the Germanic gods, Woden, Thor and Freya.

But the principal gift of Roman civilization to Europe has been the system of Roman law (*q.v.*), a system very different from that of the old tribal law of the Roman people, for it arose from the precedents created by the Roman judges charged with trying the suits of *foreigners* in Rome. Hence it became a kind of international law, derived from the mingling of the legal customs of the civilized peoples of the whole empire, elaborated and organized into a legal system in the 3rd century A.D. by the Roman jurists who were disciples of the Greek philosophers. This Roman law, permeated by the Greek spirit, rational, logical, lucid, precise, humane, which has sometimes been designated *la raison écrite*, has been preserved in the Roman countries in the guise of customary law, while it has been adopted by the Germanic peoples in the form of written law. Above all, it has become in questions of ownership and contract the source of the principle of common law throughout Europe.

Despite its extent, the Roman empire was a single State forming a single political entity under the authority of a single emperor. At the end of the 3rd century A.D., Diocletian, finding that the task of defending the frontiers was too arduous for one man, invited the assistance of a colleague, and the two emperors divided up between them the task of government without, however, destroying the essential unity of the empire. When he became sole emperor, Constantine transferred the seat of government to Byzantium which became Constantinople (*q.v.*). After the death of Theodosius in 395 the empire was divided between his two sons, and although its unity was maintained in official language, the division became permanent. Henceforth there were two emperors: the one in Italy who ruled over the Latin-speaking countries; the other in Constantinople who ruled over the Greek-speaking countries. The Balkan peninsula, which became attached to the Byzantine empire, was from that time cut off from Europe; it remained separated until the 19th century.

Christianity and the Roman Church.—It was under the Roman empire that the Christian religion, which was born in Asia, penetrated into Europe. Christianity had been organized in the Greek-speaking countries of the Near East; "Christ" and "Christians" are Greek words, and its sacred books were written in Greek. Moreover, its teaching, elaborated by the doctors and synods of Asia Minor, was called by a Greek name—dogma. Christian institutions and officers in the Christian Church bore Greek titles—baptism, catechism, hymn, eucharist, church, synod, diocese, alms, parish, bishop, priest, deacon—words which still endure in popular forms in the European languages. So long as it was opposed by the official authorities, Christianity did not make many converts in Europe outside the towns, at least among the Greek-speaking peoples. A very large majority of the population, especially the peasants, remained unaffected by it. It was not until the emperor had declared himself a Christian that the mass of his subjects followed his example, at first voluntarily, and later by his command. Before the end of the 4th century Christianity had become obligatory and the old pagan cults were forbidden. The priesthood had become an official body and formed part of the officialdom of the empire. The Church was organized within the framework of the empire and a bishop was appointed to each city. The Church adopted the Roman procedure and the official language of the empire, namely Latin; it became a Latin Church.

Christianity, as a religion strange to Europe and of urban origin, was for long confined to the towns, and only very gradually penetrated into the depths of the country districts. An ignorant population was not interested in assimilating doctrines inspired by the spirit of Eastern Hellenism and far too subtle for their comprehension. While they adopted the Christian rites they preserved old pagan customs in the form of the cult of local sanctuaries and of pilgrimages to holy places where miraculous cures were effected. The clergy themselves were little interested in theological studies. But, at least after the disappearance of the empire, it was they who maintained in Europe the memory and the love of Roman unity.

The Barbarian Invasions.—The inhabitants of central Europe, loosely attached to the soil, which they cultivated with difficulty, now and then emigrated with their families towards the south and sought to obtain lands from the Roman authorities, either by persuasion or by force. Until the 4th century, Roman leaders had always been successful in repelling these invasions. But it became increasingly difficult to maintain the strength and to pay the armies that defended the frontiers of the empire, both because silver had become too scarce to be used as pay and because the citizens of the empire had become unsuited for the profession of arms. In order to recruit its armies the empire took into its service bands of barbarian warriors; little by little the imperial armies became filled with such soldiers to such an extent that the word *barbarus* became synonymous with *miles* (a soldier). In the 5th century the armies were commanded by barbarian chiefs like Arbogast, Stilicho, Aetius, Ricimer. Certain barbarian peoples who had entered nominally into the service of the emperor, finally ended by establishing themselves within the empire; their chiefs, who bore the title of *kings*, conducted themselves as sovereigns; but there always remained an emperor in Italy. This confusion lasted for at least 100 years.

The year 376 has often been taken as marking the beginning of the barbarian invasions which opened in the history of Europe; a period known as the middle ages. In that year the Visigoths, fleeing before the Huns (*q.v.*) took refuge on the south side of the Danube, within the frontiers of the empire. At the battle of Adrianople of 378, in which the emperor Valens was killed, they destroyed a great Roman army. In 410 Alaric, their king, captured and sacked Rome. Then they passed on into Gaul, where their king, establishing himself in Toulouse, extended his power over Spain.

Other Teutonic races invaded the empire by way of the Rhine. The Vandals (*q.v.*) crossing Spain, at first established themselves in Andalusia, and later passed over into Africa, where their king established his capital at Carthage. The Burgundians, established in Savoy, in 435 extended their power over the country on the east bank of the Rhone. The Franks (*q.v.*), who owed allegiance to numerous petty kings, overran the north-eastern part of Gaul. German tribes coming from the shores of the North sea, Jutes, Saxons and Angles, settled in the south and east of Britain.

Odovocar.—In 476, Odovocar, the leader of the Barbarian warriors of the Imperial Guard, decided against the creation of an emperor, and returned the imperial insignia to the Eastern emperor. The European territory of the empire was divided up between the Germanic kings, among whom succession by right of primogeniture was customary. These lordships, scarcely meriting the name of States, differed in extent, according to the fortunes of war and the changes within the ruling families. The most extensive were those of the Ostrogoths in Italy, the Visigoths in Spain (*see* GOTHS), the Vandals in Africa and the Franks in Gaul. The most enduring was the kingdom of the Franks, founded by Clovis (*q.v.*), 486–511, which was handed down for more than two centuries in the Merovingian family, which ruled all Gaul except Languedoc, and even exerted its authority beyond the Rhine over certain tribes, in Germany. In the 6th century the emperor Justinian (*q.v.*) destroyed the Vandal and Ostrogoth kingdoms and re-established the imperial suzerainty in Africa and Italy. But a Germanic people, the Lombards (*q.v.*), overthrew it again in 568 and established their power in northern Italy and in Tuscany up to the walls of Rome.

The Arabs.—In the 7th century a barbarian people of different origin—the Arabs—united under the religious and military com-

mand of the prophet Mohammed (*q.v.*), rapidly conquered northern Africa and western Asia, then Spain and a part of southern Gaul reaching to the Rhone. Out of this conquest arose the Arab empire, which developed an eastern civilization called Arabian, unified by the Mohammedan religion, and the Arabic language and literature. Henceforth the unity of the Mediterranean world was finally broken; Africa and Mohammedan Asia remained cut off from Christian Europe. (*See* also ARABIA; CALIPHATE; ISLAM; ISLAMIC LAW; ISLAMIC INSTITUTIONS; MOHAMMED.)

Results of the Barbarian Invasions.—In the midst of the old population, no longer accustomed to the practice of arms, a new population of barbarian warriors settled down and preserved, until the 9th century, its own family system, its customs of property and legal process. The reaction of these new comers differed according to the conditions of the country in which they had settled. In the Mediterranean countries, which had not been depopulated, the Visigoths and the Ostrogoths were absorbed into the Roman inhabitants without leaving any trace. The countries bordering Germany, devastated and depopulated from the 3rd to the 5th century, were re-populated by the Germans, who brought with them customs of much greater simplicity and a great deal of natural energy. The re-population of Gaul to the north of the Loire by the Franks, of Britain by the Saxons and the Angles of north Italy by the Lombards, made these countries, which took their names (France, England, Lombardy) the centres of a new European civilization during the middle ages.

The Lombard invasion, by suppressing the rule of the empire over central Italy, isolated Rome, where the pope, Gregory the Great, 590–604, became the master of the city, obtained a practically independent political power, and by sending missionaries to England began to spread his spiritual domination over distant lands. The rupture between the Western Church and the iconoclast Eastern emperors was the final step towards the elevation of the pope to the position of a sovereign prince.

The Carolingian Empire.—The Frankish family of the Merovingians, before they ceased to bear the title of kings, were replaced in the government of the Frankish kingdom by a new family of warriors, from the district of Metz, who exercised for a century the functions of head of the royal household in the kingdom of Austrasia, where the population had remained wholly Frank. One of these warriors, Charles Martel, re-established the power of the Frankish king over Gaul south of the Loire, and expelled the Mohammedans who had come in from Spain and had occupied the country between the Pyrenees and the Rhône.

His son, Pepin, called to the help of the pope against the Lombards, delivered the land round the city, and made a donation of it to the pope, which was the foundation of the temporal power of the papacy. He took the title of king of the Franks and was consecrated by the pope in a coronation ceremony—a precedent which gave rise to the custom which has been followed by all the sovereigns of Europe throughout the centuries.

Pepin's son, Charles, called the Great (*q.v.*), who gave his name to the Carolingian dynasty, conquered the Lombard kingdom and subdued the Saxons. He extended his rule over the greater part of western Europe, from the Ebro in Spain to the Elbe in Germany. He kept the way of life, the dress and the language of the Franks, and resided for choice at Aix-la-Chapelle, in the German-speaking country. But, having gone to Rome to establish order after a rising against the pope, he allowed himself to be proclaimed emperor and to be crowned by the pope (800). There were from that time two emperors—an emperor of the East and an emperor of the West.

Charlemagne reorganized the Government by exacting obedience from the local magnates who exercised the functions of dukes and counts, and by giving official power to the prelates (bishops and abbots). He established a compulsory tithe on all produce of the soil for the benefit of the clergy; and created a joint Government of the secular and clerical authorities, which from that time governed both the subjects of the king and the members of the Church. This system of Government spread itself over the whole of Europe, and has been called "the union of the throne and the altar."

In the 8th century education had fallen so low that the clergy themselves, the sole guardians of the Roman culture, could write nothing but a kind of barbarous Latin in an almost illegible script; Ireland alone maintained in its convents the tradition of classical study. Charlemagne gathered round him the most learned men from Britain, Italy and Gaul; his court became a centre of learning, where literary works were produced of little intrinsic value and of a low intellectual content. But this "renaissance" revived the study of the Latin language and of the most celebrated Latin authors, and the recopying of the manuscripts of their works. Schools established in abbeys and bishoprics for monks and clerks revived the teaching of the Roman schools of the later Roman empire. This was the origin of the teaching, common to the whole of Europe, founded on the *trivium* (*q.v.*)—grammar, rhetoric, logic—and reducing to a few elementary rudiments the sciences of the *quadrivium*—arithmetic, geometry, astronomy, music. Finally, the Carolingian renaissance regenerated style, which had become degraded. The clerks henceforward produced their works, their letters and official deeds in correct Latin. Script became beautifully legible, in the form of the Carolingian *minuscule,* which has been perpetuated in our European printed characters.

The Dismemberment of the Carolingian Empire.—The Frankish kings, having become emperors, did not abandon the Frankish custom of dividing up their lands among their sons. The empire of Charlemagne was divided by the Treaty of Verdun, 843, between his three grandsons. Charles received the country between the Pyrenees and the Meuse, the Saône and the Rhône; Louis the country to the east of the Rhine; shares corresponding roughly to France and Germany. Lothair, the eldest, received along with the title of emperor, the Lombard kingdom (Italy) and the belt between France and Germany. His share underwent a further partition; the territory between the North sea and Switzerland fell to his son, Lothair II., who gave it his name, Lotharingia (*see* LORRAINE). The Treaty of Mersen, 870, divided this territory between the kings of France and Germany, and it has remained for more than ten centuries a bone of contention between France and Germany.

Even before the Carolingian family was extinct, the title of emperor had lapsed, and the title of king was in dispute in France. Italy and Germany between the families of lords powerful enough to secure recognition from the other chief lords of the country. It cannot be said that the monarchy became elective, for recognition did not take the form of a regular election. In the region between France and Italy, it would happen that a prince, sometimes two princes, would take the title of king without making it possible to say that there were exactly two kingdoms, for the titles were purely personal and were not attached to a fixed territory. In the same way, in Spain the Christian warrior chiefs coming from the mountains of the Asturias and the Pyrenees, took the title of king when they occupied the districts that had been evacuated since the 9th century by the Moors; sometimes they transmitted the royal title to several sons, with the result that Spain became divided into numerous kingdoms, each of which was no bigger than a province.

Invasion of the Norsemen.—The final barbarian invasion was that of the bands of Scandinavian warriors (*see* VIKING; NORMANS), who throughout all the 9th century swept the coasts in their galleys and sailed up the rivers. They pillaged the towns and monasteries and fleeced the inhabitants whom their incompetent Governments were unable to defend. They ravaged the whole of western Europe, northern Germany, Britain, France, Spain and even Italy. They made permanent settlements in England in the Danelaw and in France in the district that took their name (*see* NORMANDY), where they bred a new population remarkable for its adventurous spirit and the distinguishing features of its Nordic origin.

Alfred the Great (*q.v.*) accomplished, at the end of the 9th century in England, a task analogous to, though less great than that of Charlemagne. He extended his authority over all the English peoples who had not been conquered by the Danes. He sought the aid of the clergy in the work of government and set up clerical schools for the teaching of Latin.

FEUDAL PARTITION AND CHRISTIAN UNITY

Feudalism.—The feudal system (*see* FEUDALISM), which arose during the 9th century in the Carolingian empire, was based upon the division of the country into very large estates, held by the warrior chiefs, and upon the necessity of their maintaining bands of mounted and armoured soldiers. The soldier was bound to his lord by a ceremony of homage which created a personal bond between the lord and his vassal. For his support and the upkeep of these arms the lord gave him horses and servants and a domain with its peasants. The vassal, in exchange, rendered the lord military service and fealty. All lords who bore the title of duke or of count regarded themselves as vassals of the king; the great landowners considered that they held their estates immediately from the king or from some other supreme lord; the fiefs, as these estates are commonly called, from the end of the 10th century, became hereditary and the obligation of homage finally amounted to no more than a bare ceremony. The whole country then became divided into fiefs and the owners exercised complete power over their tenants. Europe was divided up into many thousands of independent lordships, whose owners behaved as though they were sovereigns. The countryside became covered with fortifications and castles, the seats of different nobles. As in the days before the *pax romana*, war was again the normal state of Europe.

Originating in France, feudalism finally extended over the whole of Europe with the exception of Russia and the Balkan peninsula, and gave rise everywhere to a similar organization of lay society. In every country there arose an upper class composed of warriors who owned fiefs, divided according to their wealth into: (1) titled princes (in Spain, grandees; in Germany *Fürsten*); (2) great lords (in England, barons; in Germany, *Herren*); (3) knights (*chevalier* or *Ritter*). These formed an hereditary aristocracy, to which was added, during the 13th century, the inferior and much more numerous class designated by the vague appellation of *gentlemen* (*écuyers, squires, Edelknecht*).

The peasants who cultivated the estates of the nobles on a system of fines and *corvées*, constituted a lower class of little social consequence. The new class of the *bourgeois* that arose later in the town formed an intermediate class, but the nobles never consented to regard them as equals. These class divisions were common to all countries. Thus, despite the division of political power, the unity of Europe was strengthened through the uniformity between the deepest strata of society.

The Kingdoms.—From the beginning of the 11th century, princely families who bore the title of king, sought to strengthen their power and increase their territories. Most powerful of these was the king of England, because William the Conqueror, after he had reduced the whole kingdom to obedience, had divided the land between his leading followers, thus making them his direct vassals, had forbidden private war and placed all his subjects under the control of his officers. England was the most centralized State in the middle ages. The Norman knights who, in the 11th century, founded the kingdom of Sicily and Naples (*see* SICILY) set up there an analogous system of government.

In France the royal title that had been fought for during a century between the Carolingians and the leading families of the district around Paris, after 987 fell into the possession of this family, later known as the Capetians, and finally became hereditary in it owing to the transmission of the crown without a break from father to son from 987 to 1318. But the king's authority did not run beyond his own royal domain, which was greatly reduced during a century and a half, whereas the dukes and counts who were nominally his vassals, ruled over great territories amounting to States in themselves. Thus the duke of Normandy, even before he had conquered England, was more powerful than the king, and the counts of Anjou (*q.v.*) who, at the height of their power, possessed the kingdom of England and all the west of France, were for a time incomparably more powerful than the French king. It was not until after Philip Augustus had won from John all the country to the north of the Loire that the royal domain exceeded that of other princes.

In Spain the petty Christian kings of the north, availing themselves of the break up of the Arabian caliphate, extended their authority, at the end of the 11th century, over the centre of the peninsula. The conquest of the south was undertaken along parallel lines by the three kings of Portugal, Castille and Aragon, who succeeded, in the 12th century, in conquering the small Moorish kingdoms of the south with the exception of that of Granada which did not submit until 1492. Each king created a State which formed the nucleus of one of the three nations—Portuguese, Castilians, and Catalans—each speaking its own dialect. (*See* SPAIN.)

Northern and eastern Europe were divided, until the 11th century, among tribes that were still pagan, governed by warrior chiefs, who on their conversion to Christianity, took the title of king. In this way there arose the Scandinavian kingdoms, then the Slav kingdoms of Poland and Bohemia, and the Magyar kingdom of Hungary.

The Holy Roman Empire.—In Germany the royal title, which had remained elective, was borne successively by three ducal families ruling over the chief Teutonic tribes—Saxons, Franks, and Swabians (*see* GERMANY). The Saxon king, Otto I. in 963 took the title of emperor, which from that time forth was borne by the German kings. Tradition demanded that the emperor could only be crowned in Rome by the pope. Each king therefore made an expedition to Rome at the head of an army of German princes; and at Monza, near Pavia, he also took the iron crown of the Lombard kings. Each became nominally the sovereign of Germany and of Italy, and since the 11th century, of the kingdom of Arles, which was carved out of the land between the Rhône and the Jura mountain. The most powerful of the emperors, Henry III., extended his sway over the kingdoms that bordered Germany on the east. The power of the emperors was weakened through their combat with the popes, which arose first between Henry IV. (1050–1106) and Gregory VII. on the investiture question (*see* INVESTITURE), and was continued between the Hohenstaufen emperors and the popes supported by the chief Lombard towns. (*See* GUELPHS AND GHIBELLINES.)

The Church and the Papacy.—The Church had preserved the unity of religion among the inhabitants of the Roman empire and gradually extended it to all the peoples of Europe as they became in turn converts to Christianity. Everywhere the clergy introduced the same ceremonies, the same moral laws, the same religious books, and the same language, Latin, which became the general language of culture throughout Europe. Everywhere the clergy were established on a common organization, the bishops in the cities (placed there for the express purpose of becoming the focus for a diocese), monasteries on the great estates, and the priests in the parishes. The clergy recruited in a barbarian society paid little regard to a rule of discipline which imposed upon them so different a life from that of the layman. It was this tendency of the clergy to take their morals from the age in which they lived which provoked the reform of the monastery at Cluny in the 10th century (*see* MONASTICISM), and which brought about, in the 11th century, during the papacy of Gregory VII., the fight against simony (*q.v.*) and the marriage of clergy.

The pope, who had become powerless in the 10th century, regained his authority over the clergy in the 11th century. In the 12th century he freed himself from the power of the emperor by organizing the college of cardinals; and asserted his authority over the layman by submitting him to ecclesiastical jurisdiction in matters of marriage and inheritance, and above all in criminal jurisdiction against heretics. After the crusade against the Albigenses (*q.v.*), the pope set up an extraordinary tribunal called the Inquisition (*q.v.*), charged with the extirpation of heresy. The Lateran council, in 1215, imposed upon all princes the duty of exterminating heretics and upon all the faithful, the obligation of confession. Two orders of friars were created—the Franciscans and Dominicans (*qq.v.*)—who, instead of retiring from the world, lived in the cities among the people and carried on work as preachers. The uniform system of repression, supervision and preaching, was established in every country in Europe, and thus European unity was set up under the absolute authority of the pope, after the model of the imperial Roman system. A Byzantine writer remarked that Pope Innocent III. had become the successor of Caesar rather than of St. Peter (*see* PAPACY).

The Crusades.—The crusades were an enterprise undertaken in

common by the laity and clergy of Europe for the deliverance or defence of the sepulchre of Christ, the object of the veneration of all Europe (*see* CRUSADES). The pope preached the first crusade and superintended its conduct through a legate; the other crusades were preached by monks and priests. The princes and the knights assembled their forces for the conquest of the Holy Land. The Italian seaports—Venice, Genoa, Pisa furnished the siege-engines for attacking fortified towns and ships to transport the crusaders. Knights from all the different countries of Europe, united for the first time, learnt to know each other and to organize themselves to work together.

The first result of the crusades was the creation of little ephemeral kingdoms that the Mohammedans were not long in destroying; the indirect results are still matters of controversy. The 19th century tended to exaggerate them. There is no longer any means of estimating the part played by the crusades in the social and political evolution of Europe, and we cannot even attribute to them the establishment of commercial relations between Europe and the Levant, nor the introduction into Europe of the industries and arts of Eastern lands like sugar, paper, drugs and articles of luxury. For contact with Arabian civilization had been established on the Mediterranean sea-board through commerce with Moorish Spain, Sicily, Egypt, and the Byzantine empire.

Chivalry and Courtesy.—From the 12th century onwards the knights organized themselves into a close corporation to which no one was admitted except by a ceremony of initiation. Its members were inspired by an *esprit de corps* and spared each other mutually in battle. They conducted themselves in accordance with the rules of chivalry, which were inspired before all things by the idea of personal honour. The knightly ideal was that of bravery and loyalty and the sanctity of the pledged word. Later still there was added to this the duty of succouring the weak and the oppressed. The customs of chivalry and the knightly ideal permeated throughout Europe and laid the foundations of a common morality for the whole aristocracy of the continent.

The princely courts, where large numbers of noble courtiers lived in close contact, became under feminine influence the centres of that polite usage known as courtesy, which spread gradually into all the European courts and became the model for the whole aristocracy of Europe. Out of this there arose a new member of society—the lady—a personage unknown to antiquity or to the East, and remaining ever since one of the most original characteristics of European society. Before the close of the 12th century there arose in the French courts a new relationship between the sexes, the *amour courtois*, which was founded on a respect displayed towards a lady to which expression was given in the feudal terms of homage and the service of love. From being a court custom this practice passed into the knightly ideal and was disseminated by means of romances and poetry, under the form of gallantry, amongst the whole aristocracy of Europe. It introduced into European manners, regard and respect for women, and thus helped to raise the condition of women in European society to a higher level than that attained by them among other Christian societies.

The Universities and the Colleges.—The clergy alone knew how to read and write as long as Latin was the sole medium of communication. The clergy were the professional scribes of the period, to which the persistence of the name "clerk" bears witness. The majority of the clergy received only the tonsures and entered only the minor orders, and very many were married. Masters and pupils living in the same town united to form an association called a University. The University of Paris, founded in the 13th century, was divided into faculties, according to the subjects taught. The biggest was the faculty of arts and was composed of teachers who gave the preliminary instruction in Latin necessary to enable the scholars to study theology and law. The younger scholars were organized in colleges and subjected to a discipline modelled upon that of the monasteries. The courses of study were divided into grades (or degrees) and in order to pass to a superior degree the pupil was subjected to a test called examination (*examen*).

The University of Paris became the centre of international scholarship. To the lectures came scholars and professors from all Europe, and the most celebrated of its teachers were foreigners, like Thomas Aquinas, Albert the German, Duns Scotus from the British Isles, and Raymond Lulle from Spain. The University of Paris furnished the model for those in England, Germany and all the countries of Europe, with the exception of Italy. Thus Europe had attained to a common system of teaching which differed profoundly from that of antiquity and the East—a system which has persisted to the 20th century, with its same peculiar terms (university, faculty, college, rector, bachelor, master, doctor, examination, thesis), and even with its academic dress and insignia. It remains the foundation of the intellectual unity of Europe.

Another form of intellectual unity was afforded by arts and letters. Gothic architecture, originating in France in the 12th century, was introduced into all the Roman Catholic countries of Europe and along with Gothic sculpture, prevailed throughout western Europe, down to the end of the 15th century.

Books written in Latin—the international language of Europe—were addressed to a European public. They treated principally of theology and philosophy (*see* SCHOLASTICISM) and chiefly emanated from the universities. In common with scholasticism and the universities, they possessed an international character. Books in the vulgar tongue were primarily addressed to a national public. But certain poems written in Romance, lyrics or epics, songs or ballads were translated or imitated in the languages of other European countries. Thus there arose under French inspiration a common European literature, which is the origin of the prose romance, the distinctively literary form of Europe.

The Revival of the Towns.—The towns that in ancient days had been the centres of European civilization had been reduced during the dark ages to the condition of small fortified strongholds in which the few inhabitants lived under the absolute authority of, or even in personal service to a lord. By degrees, as the use of money was restored in Europe, the towns reopened their markets and became once more centres of manufacture. The populations increased and became richer and less dependent upon a lord. The merchants organized a transport system chiefly by sea or along the rivers.

The renaissance of the towns began in Italy in the Mediterranean ports, which had commercial relations with Constantinople and the Arabic countries which were then more civilized than Europe, and it penetrated into France and Germany through the seaports or towns situated on the highways of international commerce. In eastern Europe, which remained agrarian and but half civilized, the towns developed much later and only began in the 14th century to model themselves on those in the more civilized countries, above all Germany, and were inhabited in part by foreigners who brought with them and kept their own customs and languages.

The political organization of the towns widely differed in accordance with their degree of independence towards their respective lords. Two Italian seaports Venice and Genoa, and Florence, the centre of the woollen industry, were organized as sovereign States governed by an aristocracy of merchants. The towns in Italy and Germany nominally owing allegiance to the emperor, became under the name of "free cities" or "imperial cities" small independent republics which raised their own troops and coined their own money. The towns organized on a communal basis by an association of the citizens under the charter of the lord, acquired little by little the power of the lord and were governed by a council and elected magistrates. The towns that formed part of the royal domain in England, France and Spain continued to be governed by the king's representatives. A common characteristic of all European towns was the fixing by a written code of the taxes, fines and penalties due from the inhabitants.

The inhabitants of fortified towns received a new name, in Latin *burgenses*, from the German word *burg* meaning a fortress. They formed an intermediary class between the nobles and the peasants. For the most part they consisted of artisans who in the northern countries set up corporations for each particular trade (*see* GILDS), which laid down regulations for its conduct and supervision. Above the mass of the population there existed an aris-

tocracy of merchants, lawyers and officials which in France finally came to be known by the name of *bourgeois*.

The Decline of the Empire.—The emperors, backed by the prestige of their title and of the extent of territory nominally rendering them obedience, long sought to compel the monarchs of the various European States to submit to their authority. In this they were not successful, although the Hohenstaufen emperors at least exacted obedience from the German princes. From the time of the Great Interregnum (1254–73) the title of king of Germany which it was necessary to possess in order to become emperor, ceased to be held permanently by one family; the princes threw off all authority and Germany became a chaos of dukes, counts, lords and prelates, each of whom governed his own territory as a sovereign lord. Rudolph of Habsburg, who was elected king in 1273, used his power to acquire the duchy of Austria and the surrounding territories which came to form the hereditary domain of his family with Vienna as capital. The emperor Charles IV., who was descended from the French house of Luxembourg, published the Golden Bull (*q.v.*) which regulated the system of election to the empire and reduced the electoral princes (*Kurfürsten*) to the number of seven. But the emperor in fact enjoyed only a nominal authority, and the countries of central Europe, which had become a dependency of the empire, Germany and Italy, remained divided up into small States until the 19th century.

Growth of the Royal Power.—In western Europe the kings enlarged their domains and increased their power throughout the 14th and 15th centuries. The English king reduced Wales to submission, and Edward I. and Edward III. increased their authority by their conquests. In France, however, the royal authority was checked by the Hundred Years' War (*q.v.*), which opened a period of defeat (Crecy, Poitiers, Agincourt), by English invasions and disastrous treaties which on two occasions, in 1358 and 1422, ceded to the king of England a great part of France. But at the end of the 15th century the French king succeeded in uniting to his royal domain nearly all the provinces, as well as a great part of the country between the Rhone and the Alps. Moreover, the feudal service of the vassals no longer sufficed to carry on wars of long duration and the kings therefore enlisted companies of fighting men to whom they gave pay (*solde*); from whence arose the name of soldier (*soldat*). This professional soldiery was often at the service of the highest bidder.

In Spain the king of Aragon, who had at his command the naval forces of Barcelona, conquered Sicily and Sardinia. The two great kingdoms of the peninsula were united by the marriage of Ferdinand of Aragon with Isabella of Castille in 1474—a marriage which led to the establishment of the Spanish monarchy.

In eastern Europe the three Scandinavian kingdoms were united under the sceptre of the Danish king by the Union of 1397. The grand-duchy of Lithuania (*q.v.*) was united to the kingdom of Poland (*q.v.*) through the grand duke's marriage in 1387 with Hedwig, the heiress of Poland. Separated from Germany during the Hussite wars Bohemia formed a national State which was united under the same dynasty with the kingdom of Hungary.

Legislative Assemblies.—During the later 13th century kings of England had been in the habit of assembling the great men among their subjects in order to receive their counsel and assistance in times of grave crisis. The lords and the prelates came in person; the gentlemen and the townspeople were represented by deputies. This custom was gradually adopted by kings and princes throughout nearly the whole of Europe. The assemblies took names in different countries: parliament in England; *cortes* in Spain; *états* in France; *Landtag* in Germany; and in the central European kingdoms the Latin name of diets. These assemblies were ultimately divided into sections that differed in the number and composition of their membership. Thus in England, Hungary, Castille and Poland they became divided into two chambers—the lords and the commons; in France into three—clergy, nobles, bourgeois; and in Germany into lords, gentlemen and towns. The kings chiefly employed these assemblies for the purpose of augmenting the revenues, adding to the products of their domains by the taxes which the assembly consented to levy on their subjects. At first temporary, these taxes became permanent in character and were the means of enabling the rulers to maintain a permanent army.

The Crisis of the Papacy.—While the power of the kings and princes increased, that of the papacy was weakened by a series of crises. After the quarrel of Boniface VIII. and Philip IV. the popes took up their residence at Avignon where they lived under the tutelage of the French kings—a period known to Italians as the Babylonish captivity. The return of the pope to Rome in 1377 brought about the great schism between the pope living in Rome and a rival pope in Avignon, and while each excommunicated the supporters of the other, Europe was divided into two hostile camps. This quarrel had the effect of lowering the clergy in the eyes of the laity and in making the latter alive to the abuses that crept into the Church. The Councils of Constance and Basle, which were composed of prelates and doctors from all Europe, sought to reform the Church by restoring the authority of the Canon law; they claimed to represent the Church Universal and to be superior to the pope. The Council of Constance was successful in re-establishing unity in the Church by electing a pope in 1410, but both councils failed in their attempts to reform and in their endeavour to suppress the Hussite heresy. (*See* Papacy; Basle, Council of; Constance, Council of; etc.)

Fall of Constantinople, 1453.—The capture of Constantinople by the Turks was a startling occurrence and spread terror throughout Europe. It has long been taken to mark the close of the middle ages. But the results which have been attributed to it had already made their appearance before the fall of the city. The Turks were already masters of the Balkans and had made an end to the trade of the Italian cities with the Black sea ports. The works of Greek writers had been introduced into Europe by the Byzantine scholars who attended the Council of Florence at which it was sought to bring about the reconciliation between the Greek Church and that of Rome.

The Turks continued to threaten Europe; they were organized for continuous warfare, and they possessed an infantry and artillery superior to those of the Western European States. The invasion reached the plain of the Danube and twice, in 1529 and 1683, the Turkish army stood before Vienna.

ABSOLUTE MONARCHIES AND THE REFORMATION

Establishment of Great Monarchies.—Towards the end of the 15th century the three great nations of western Europe—England, France and Spain—formed each a national state, united under the unrestricted authority of a single sovereign, reigning by hereditary right. He judged his people in his courts, controlled them through his officials and taxed them. In France and Spain he maintained an army whose commanders he nominated. He determined peace or war.

The French king, who ruled over the most populous and fertile of the three kingdoms, was possessed of ample revenues and an exceedingly powerful army. He took part in the Italian wars (1494–1513) in order first to conquer the kingdom of Naples and then Milan. His plans were frustrated by a coalition of the Italian States and subsequently by Ferdinand, king of Aragon, who was already master of Sicily, and Pope Julius II., who was supported by the Swiss and the emperor. As a result the French armies were driven out of Italy.

The Habsburg family had been possessed of but a small hereditary domain, but its importance was increased by its imperial elevation in 1439, and it soon raised itself to the first rank by marriage alliances, following the method epitomized in the half line: *Tu, felix Austria nube*. Maximilian (*q.v.*) had married, in 1477, the duchess of Burgundy, who was heiress of the Low Countries, and her son, Philip, married Joanna, heiress to the two Spanish crowns, who transmitted the whole inheritance to her eldest son, the emperor Charles V. The younger son, Ferdinand, married the heiress of Bohemia and Hungary and brought these two kingdoms into the hereditary possessions of the Habsburgs, who thus came to rule over a great part of Europe.

The Renaissance.—The Renaissance (*q.v.*) was a European event in the sense that it gave rise to an artistic technique and

ideal, common to all Europe. It was preluded by the invention of printing which made possible the publication of the Greek and Latin classics, and by facilitating their study gave birth to the Humanism (*q.v.*) that was the essential characteristic of the Renaissance.

The task of the Renaissance was not only to foster the arts which had been flourishing since the 12th century, but also to imitate classic art as the Italians knew it. The Renaissance rejected the pious and ascetic Christian ideal of the middle ages and returned to a pagan worship of beauty in the study of the nude and of mythology. It replaced Gothic sculpture and architecture by imitations of Roman statues and monuments; and in literature writers returned to the literary forms of the ancient world—tragedy, comedy, epic. The Renaissance began in Italy in the 15th century and there reached its zenith after the beginning of the 16th century with Raphael and Michael Angelo; it spread during the early 16th century into Germany and France, reaching England towards its close during the lifetime of Shakespeare, and entering Spain at the beginning of the 17th century in the days of Cervantes and Velasquez.

The Renaissance caused a cleavage in the artistic and literary life of Europe by creating an informed and highly polished literature and art that could not be understood by the uneducated, but were for those alone who had received a training and education preparatory to their enjoyment. The most famous artists and writers worked solely for a privileged public and their works never reached the mass of the people, who were forced to be content with popular forms of literature and art that were scorned by the learned.

The Reformation.—The reforms demanded in the 15th century by the councils for the purpose of restoring discipline in the Church, although they upheld the principle of papal authority, were frustrated by the opposition of the popes. The Reformation in the 16th century took the very different form of a revolt against the pope, and involved a far-reaching change in the organization of the clergy and the rites of the Church (*see* REFORMATION). It was the work of theologians who sought to restore the purity of Christian belief by establishing it on the study of the Holy Scriptures.

The clergy, who were in possession of powerful weapons for the discovery and destruction of heretics, had always been successful up till then in suppressing revolts. The reformers were able to preach their doctrines and organize churches only in countries in which they were supported by the secular power. All the great monarchs were opposed to them. The reformed churches of Luther in Saxony, of Zwingli at Zürich, of Calvin at Geneva, were all established in countries nominally dependent on the empire; and the propagation of the Reformation was rendered possible only by the continuous warfare between the monarchs of the several States and by their quarrels with the pope.

The Lutheran Reformation was adopted by nearly all the secular princes and towns in Germany because, through it, they profited by seizing the ecclesiastical estates and freeing themselves from ecclesiastical jurisdiction; and it was also accepted by Denmark and Sweden. Calvinism spread at a later date, in spite of the opposition of the rulers, in France, Scotland, the Netherlands, and in Hungary, Bohemia and Poland. After sudden changes of policy, the English kings established the Anglican Church which, while preserving much of the traditional ceremonies and organization, adopted a Protestant attitude.

The Counter Reformation.—The clergy, disorganized and at variance among themselves, were unable to prevent the growth of the Reformation. The opposition was first promoted by the monastic orders, chief among which was the order of the Jesuits (*q.v.*) who placed their entire resources at the service of the pope; then by the Council of Trent (*see* TRENT, COUNCIL OF), summoned by the pope with the support of the kings of Spain, France and Germany. This council did not re-establish the unity of the Church as had been hoped; but it maintained the authority of tradition, confirmed all the rites of the middle ages, and preserved intact the organization of the clergy. It reformed the Church, but only in the sense of re-affirming already accepted practices. Bishops were instructed to supervise the conduct of the clergy, and the teaching of the catechism, and to establish seminaries for the education of the priests. Then followed the movement known as the Counter Reformation, directed by the pope and the Jesuits, with the object of regaining the ground lost to the Reformation. It was successful in all the dominions of the house of Austria, and in Poland, Belgium and Ireland; and Calvinism in France was sensibly weakened. The religious unity of Europe was broken for ever. The Roman Catholic Church maintained its power in all the Latin countries, in most of France and in Poland and the Habsburg lands. In the northern countries the reformed churches, which were classed together as Protestants, prevailed. Germany was divided between the two.

Conflict Between France and Austria.—The two most powerful monarchies in Europe took part in a contest which, under three different forms, lasted from 1521 to 1648. It opened with the personal rivalry between Francis I. and Charles V. Francis, when defeated, allied himself with the opponents of the Church, the Lutheran princes in Germany, and with the enemies of Christianity, the sultan of Turkey and the Corsairs. Although Francis was unable to hold his conquests in Italy, his successor, Henry II., with the help of the princes, defeated the attempt of Charles V. to render Germany submissive. The defeat of the emperor was acknowledged in the Peace of Augsburg in 1555, which recognized the independence of the princes and their right to impose the Lutheran religion upon their subjects.

The war which had been going on between the French and Spanish kings was finally ended by a peace, concluded in 1559, for the purpose of extirpating Calvinism. This task was undertaken by Philip II. of Spain, who, after his conquest of Portugal in 1580, sought to re-establish Catholicism in England, France and the Netherlands, and to establish his supremacy in Europe. Philip sought to take advantage of the religious wars in France that lasted from 1562 to 1598 and of the conflict between Elizabeth and Mary Stuart over the succession to the English throne.

He leagued himself with Henry of Guise, the head of the League, and with the Jesuits and the English malcontents. After he had reconquered Belgium he made ready to attack Henry III. and Elizabeth simultaneously. But the disaster of the Armada ruined all his plans in 1588, and all the people whom he had threatened —English, French, Dutch, German—allied themselves against him. Spain was ruined, unable to reconquer the Netherlands, and incapable even of defending her coasts against the English fleet. Henry IV. revived the royal power in France and forced Spain to sign the Peace of Vervins in 1598.

The Thirty Years' War.—The German branch of the house of Habsburg, which held the title of emperor, was greatly weakened by quarrels between the archdukes and by revolts on the part of the Protestant nobility in Bohemia, Moravia, Hungary, and even in the archduchy of Austria. The German princes were divided into two hostile camps; the Protestant Union, which was established in 1608, and the Catholic League, established in 1609. The unity of the Habsburgs was restored on the accession of Ferdinand II. in 1618; but in that year the revolt of the Protestant nobility in Bohemia—who chose as king the elector palatine, leader of the Protestant Union—opened the Thirty Years' War (*q.v.*). Led by Maximilian of Bavaria and Philip III. of Spain the Catholic League allied itself with the emperor. The war was successively waged in all parts of Germany. Wallenstein (*q.v.*), who had raised an army for the service of Ferdinand, supported it by levies exacted from the country he occupied and used it in an attempt to re-establish the arbitrary authority of the emperor over the German princes. Ferdinand became powerful enough to confiscate the territory of the duke of Mecklenburg and to take away from the princes the Church lands which they had seized.

The war was extended by the intervention of Gustavus Adolphus, king of Sweden and ally of France, who invaded Germany and forced the Lutheran princes to make common cause with him. His victories destroyed the hopes of the emperor; but after his death in 1632 the reverses sustained by the Swedish

armies and by the German princes, determined the French king to take part in the war in 1635 and to fight simultaneously the Habsburgs in Germany and in Belgium. Sweden, the United Provinces, and the Protestant princes of Germany allied themselves to a Catholic France, directed by a cardinal, and thus the war lost its character of a contest between two religions. Spain was rendered powerless by a revolt in Portugal and Catalonia in 1640; and after many abortive attempts France and Sweden undertook a common action on the Danube and in Bohemia directed against Vienna. The war ended in the defeat of the emperor and of the last attempt at hegemony in Europe on the part of the house of Habsburg.

Treaties of Westphalia, the Pyrenees and Oliva.—The Congress of Westphalia (*see* Westphalia, Treaty of), where peace was concluded in 1648, marks an epoch in the history of Europe. This congress was the first at which representatives from the great majority of the European States were assembled. Its acts were drawn up in Latin as being the international language of the day. At this congress the order of precedence among the States was established and the precedents that have since been followed in European diplomacy were there created (*see* Diplomacy). The treaty left the emperor with merely a nominal sovereignty over Germany; it confirmed the independence of the princes, lords and towns (to the number of about 300) and recognized their right of making laws, of declaring and carrying on war and of concluding treaties with foreign Powers.

Ravaged and depopulated by the war, Germany lay broken up and at the mercy of an invader; but war went on between France and Spain; and Charles X. of Sweden, already master of a great part of the Baltic sea-board, plunged into war against Poland (which was, for the moment, at his mercy), Russia and Denmark, and almost captured Copenhagen. The elector of Brandenburg seized the opportunity to make himself master of the duchy of Prussia. War in the west of Europe was terminated by the Treaty of the Pyrenees in 1659, which left Spain finally ruined and incapable of defending her possessions. The northern war was brought to a close by the Treaty of Oliva in 1660, which left the control of the Baltic in the hands of the king of Sweden.

Louis XIV.—Richelieu and Mazarin had broken the opposition of the nobles and the *parlements* and had established an absolute monarchy in France. Louis XIV. profited by their work throughout the whole of his long reign (1643–1715). He ruled over the most populous kingdom in Europe, possessed the greatest army of the day, the most experienced generals and the cleverest diplomats. He took up his residence in the palace which he built at Versailles, where he organized a court ceremonial which rendered the person of the monarch the object of a form of worship, and his court became the focus of society and fashion. The princes of Europe, above all in Germany, dazzled by the magnificence of Louis XIV., sought to model themselves upon him. Versailles became the pattern for all courts, its etiquette the precedence for all ceremonial, and French fashions were copied in every country. Famous writers who sang the praises of the great king aroused throughout Europe an admiration for French literature and French customs; French became the language of polite society and, after the Congress of Nijmwegen in 1678, the language of European diplomacy.

Revolution in England.—The two English revolutions had political consequences of lasting effect in Europe. The Great Rebellion began with the Bishops' wars (*q.v.*) with Scotland and a revolt occasioned by a dispute over the liturgy and episcopacy. Its outcome was a republic ultimately founded on new principles—the sovereign right of the people, the electoral nature of power, and the equality of civil rights—principles which were put into application in two American colonies, Connecticut and Rhode Island. It was the origin of a type of government new to the world—democratic representative government.

The revolution of 1688 was a revolt of the English Protestants against a Roman Catholic king who sought to make Roman Catholicism the religion of England. It finally turned the English monarchy into a constitutional monarchy controlled by parliament. Locke, a survivor of the first revolution, formulated in 1689 the theory of limited monarchy, and of religious toleration in 1690; the basic principles of the political philosophy of the 18th century. Thus in the zenith of the absolutism of the 17th century the English nation had already laid the foundations of the political system of 20th century Europe.

Louis XIV. and the Supremacy of France.—Europe was now divided up between a number of powerful military States and a number whose feebleness was due either to their small size or to their being too disorganized to be capable of defence. The powerful States sought, by conquest or marriage, to acquire the territories of the weak ones. These arenas of war and of diplomatic intrigue covered the small divided States of Italy and Germany, and, in eastern Europe, the shores of the Baltic and the valley of the Danube. The once powerful Spain had become incapable of defending her external possessions, and the approaching extinction of the dynasty aroused the rivalries of the various claimants. France had an advantage over the other Powers in that the emperor was occupied in repelling the Turks, and Charles II. of England was not ambitious of engaging in Continental wars. Unable to obtain the succession to the Spanish crown in the name of the Infanta, his wife, Louis XIV. went to war in order to conquer a part of the Netherlands. The intervention of Holland checked him in 1668, and he invaded that country in 1672. His further progress was arrested by a coalition of the United Provinces, the emperor, the German princes, and Spain, which forced him to evacuate Holland and to transfer the war to the district of the Rhine and Moselle. But the coalition proved too weak to overthrow Louis XIV., and the Peace of Nijmwegen in 1678 was concluded at the expense of Spain. In 1683, when the emperor, the German princes and Poland were fully occupied in repelling the Turkish invasion, and the forces of Austria were engaged against the Turks in Hungary, Louis XIV. seized the opportunity to extend his territory through the *Chambres de Réunion* and also annexed Strasbourg in 1681. The German States could only reply with the defensive League of Augsburg (1686).

The political situation was completely altered by the English revolution of 1688 which brought England and Holland into the coalition concluded at the Hague. Henceforward, even his victories proved useless to Louis XIV., and with his finances and his armies exhausted, he was compelled to sue for peace. By the Treaty of Ryswick in 1697 he restored all the territories which he had annexed in time of peace, with the exception of Strasbourg. By the Treaty of Carlowitz in 1699, the emperor forced the sultan to surrender all Hungary; and, mistress of the Danube, Austria became once more a great Power.

Louis XIV. appeared to have regained the hegemony of Europe when the succession to the Spanish crown was secured by will to his grandson, the duke of Anjou. But the Spanish and French monarchies were not to be united under one sovereign. The emperor undertook the War of the Spanish Succession with only a few German princes for allies. Louis XIV., through his hostile measures, aroused the indignation of the English and the Dutch and caused them to enter into a new coalition against him. The ally of Spain and of Bavaria, Louis XIV. had at first the advantage of carrying on the war in Belgium, Bavaria, and in Italy, but after Marlborough, who commanded the Anglo-Dutch army, and Prince Eugene, the imperial commander, had joined forces in Bavaria and won the decisive victory of Blenheim, the French armies were driven out of Germany (1704), and out of Belgium and Italy (1706). When the Allies invaded an exhausted France, Louis XIV. sued for peace from 1709 onwards, without being able to obtain acceptable conditions; and he was only saved by the advent to power of a Tory ministry which withdrew England from the war in 1711, and negotiated the Treaty of Utrecht in 1713. In 1714 the victories obtained by the French armies over the imperial troops, compelled the emperor to accept the peace of Rastadt.

The Entry of Russia into Europe.—United since the 17th century under the sceptre of the tsar of Moscow, Russia has continued separate from Europe by religion and custom. The Russian people held the Orthodox faith and had adopted oriental

customs like long robes, the seclusion of women and the knout. Peter the Great (1689–1725) took the European title of emperor and sought to transform his empire into a European State. He compelled his subjects to adopt European clothes and European customs; he opened communications with Europe by conquering the Baltic provinces; he built in this Europeanized land a capital with a German name, St. Petersburg (Leningrad). He created a navy on the English model, an army on the German model, a senate in imitation of the Swedish senate. He organized the Russian Church after the Lutheran pattern and divided Russian society into classes in imitation of European society—an aristocracy composed of landowners, a middle-class composed of merchants.

Peter the Great made war on Sweden, compelled her to cede its Baltic provinces, thus making an end to Swedish supremacy in the Baltic and in 1709 destroyed her army. In 1717 he forced Poland to enter into an agreement which, by limiting the strength of the Polish army, placed the country in the power of Russia. Although the immense country of which he was lord was very thinly peopled (the census of 1723 reckoned the population at 14,000,000), Peter the Great possessed a large and disciplined army recruited from the peasants, and the Russian empire was henceforth one of the great Powers of Europe.

Balance of Power.—The Treaties of Utrecht and Rastadt marked the close of French hegemony in Europe. England retained possession of her conquests of Gibraltar, Minorca and Nova Scotia. The Habsburgs acquired the scattered possessions of the Spanish monarchy—Belgium, the Milanais and the kingdom of Naples. But France, though conquered, suffered no loss of territory. Two new kings, in Germany the king of Prussia, and in Italy the king of Sardinia, founded two kingdoms of no great size but possessing powerful armies which enabled them to play a part in diplomacy and war, and caused them to become, in the 19th century, the rallying points of German and Italian unity.

Henceforth relations between the European States were based on the principle of the balance of power (*q.v.*) between the great Powers, England, France and Austria, later joined by Russia and Prussia. Henceforth policy had no other aim than "the interest of the state," by which was implied aggrandisement and the great Powers sought to acquire new territory at the expense of the lesser, seeking at the same time to prevent any one among them from becoming supreme by maintaining a balance between themselves. Whenever a Power was seen to be growing over-strong, the others demanded a "compensation," to increase their strength and thus to preserve the equilibrium.

The establishment of the balance of power was followed by the peace (1714–40) which arose out of the accord between the British Government under Walpole, and the French, which was in the hands of the regent and Fleury. Only a few crises disturbed the general peace; the intrigues of Elizabeth Farnese, queen of Spain, who sought to obtain kingdoms for her two sons, involved Spain in very brief wars and in changes of alliance which called for the diplomacy of all Europe; and the election of the king of Poland in 1733 resulted in a short war against the emperor, which assured the kingdom of Naples to Charles of Spain and the reversion of Lorraine to France.

The Anglo-French and Austro-Prussian Wars—1740–1763.—Before the middle of the century, however, Europe was dragged into war by two distinct disputes that arose from different causes, but became artificially connected as one European war, viz., the rivalry between Great Britain and France in America and India, and that between Austria and Prussia in Germany. The result was two wars of the same duration, both broken by an interval of peace. The first began in America and was occasioned through the English trade with the Spanish colonies. It was fought between England and Spain, the ally of France, simultaneously with the war waged in Germany against the emperor by France and her allies, the German princes. The British king took part in the latter as the ally of Austria, while the king of Prussia seized the opportunity to conquer Silesia. This war of the Austrian Succession (*q.v.*) ended in the Treaty of Aix-la-Chapelle in 1748, peace being restored to Europe at no heavier cost than the cession of Silesia to Prussia, of a small part of the Milanais to the king of Sardinia, and of the duchy of Parma and Placentia to the second son of the queen of Spain.

The second war, the "Seven Years' War" (*q.v.*) lasting from 1756 to 1763, also had its origin in the quarrel between the French and British colonists in America, and was accompanied on the European Continent by a war directed against the king of Prussia by a coalition of three great Powers, France, Austria and Russia, joined by Sweden and the German princes. In order to guarantee Hanover, the British Government in 1756 concluded with the king of Prussia a treaty which transformed itself into an alliance.

This change in the system of alliances, which was in marked contrast to the traditional French policy of hostility to Austria, was confirmed by the Franco-Austrian *entente*, resulting in the marriage of the archduchess Marie Antoinette with Louis XVI. Frederick the Great attacked by Austria, Russia and France overcame each of them in turn; but his tiny kingdom was exhausted, and on three occasions, 1757, 1759 and 1761 he believed himself lost. He was saved by the death of Elizabeth, empress of Russia, in 1762; and in the following year the Treaty of Paris, which deprived France of Canada, set the seal upon British supremacy in America and on the seas, while the Treaty of Hubertusburg, by which Silesia was ceded to Frederick, crowned that monarch's achievement in making Prussia a great power (1763).

The Doctrines of the 18th Century.—The practice of political liberty and religious toleration, which had been established in England since 1688, not only inspired the teaching of Locke but also as the "natural religion" of the free-thinkers, spread among the educated classes. It was founded on belief in the goodness of God and in the immortality of the soul and, in opposition to ascetic Christianity, which believed human nature to be essentially evil, held that it was good, simply because it was a creation of a benevolent deity. This optimism became the common foundation of natural philosophy and political economy and overthrew, among thinkers throughout Europe, the moral concepts formed by a long tradition of Christian theology. In Germany it was disseminated under the name of *Aufklärung* and became the inspiration of such classic poets as Lessing, Goethe and Schiller; and it justified the new economic doctrine of *laissez faire, laissez passer*, which had been formulated by the French physiocrats and systematized by the Scotsman, Adam Smith. The French "philosophes," by their writings, were chiefly responsible for the spreading of these new ideas through Europe; and they were admirers of England, where many of them had lived and which they held up as an example to the world. Montesquieu was above all interested in political liberty; Voltaire specially advocated religious toleration; and such writers won a European reputation, their works helping to create in the sphere of politics and morals a common public opinion among the intellectual aristocracy of Europe.

The effect of these doctrines upon the sovereigns and their ministers since the middle of the 18th century was very unequal. Even when they admired Montesquieu they cared little for political liberty, and religious toleration was dearer to them only because it weakened the power of the clergy. Nevertheless, they were nearly all influenced by humanitarian ideas, which they sought to put into practice by founding charitable institutions, abolishing torture and cruel punishments, and adopting measures likely to result in the welfare of their subjects. A few even agreed to the liberty of industry and commerce for which the economists clamoured while protesting that their political ideal was that of the paternal despotism obtaining in China; all were agreed in upholding the absolute power of the State and hence it came about that this form of government received in Germany the name of "enlightened despotism." This was the inspiration of Pombal in Portugal, Tanucci in Italy, Florida Blanca in Spain, Turgot in France and of the sovereigns, Frederick II. in Prussia, Catherine in Russia, Leopold of Tuscany, and above all of Joseph II. of Austria, who received the nickname of "the crowned philosopher."

The Eastern Question.—The countries which had taken part

in the great wars above mentioned were successful in maintaining peace for a quarter of a century, and the peace so established was only disturbed in Europe by the two attempts of Joseph II., in 1779 and 1785, to conquer Bavaria, for the War of American Independence, in which France fought against England in America and on the seas, did not much disturb the peace of Europe.

But in eastern Europe a serious crisis arose when Catherine II. dispatched troops to Poland to subdue the Poles. The accidental invasion of Turkish territory by Russian troops, led to the war (1770–74) between Russia and Turkey. Austria entered into occupation of part of Poland, and Frederick II. took the opportunity to propose to Catherine a scheme that resulted in the first partition of Poland (1772) between Prussia, Russia and Austria —the partition inspired by the principle of "compensations" (*see* POLAND). The peace that was concluded with Turkey in 1774 at Kutchuk Kainardji gave Catherine an excuse for seizing the Crimea in 1783, while the war at sea afforded her the opportunity of forming the armed neutrality of the North (1780), directed against British naval supremacy.

So weak did the Ottoman empire appear that Joseph II. and Catherine entered into an alliance to partition Turkey in Europe. But the war against Turkey turned out disastrously. Austria was paralysed by revolts in Hungary and Belgium against the reforms initiated by Joseph II. and Russia was held in check by the attack made upon her by Gustavus IV. of Sweden. Catherine and Joseph were compelled to abandon their project and to conclude with the sultan the treaties of Sistowa in 1791, and of Jassy in 1792. (*See* also EASTERN QUESTION.)

THE FRENCH REVOLUTION

The revolution of 1789 at first amounted to no more than a national attempt to establish in France a régime of political liberty under the guarantee of a Constitution after the American model, and to abolish the rights possessed by the nobles over the peasants. Nothing was further from the thoughts of the leaders of the movement than armed intervention in Europe, and the Constituent Assembly proclaimed its intention of never engaging in a war of conquest. But the French émigrés and Louis XVI. sought help from the European sovereigns in order to restore the *ancien régime,* and the emperor and the king of Prussia, who had been reconciled to one another at Reichenbach in 1790, made common cause against the revolution. Both the Girondins, who desired war in order to effect the destruction of the king, and a ministry which equally desired it for the strengthening of the royal power, influenced the Assembly to declare war upon Austria in April 1792. The French armies, leaderless through their officers being *émigrés,* were on the point of dissolution, and when the Prussian army invaded France it was only checked at Valmy (Sept. 20, 1792). Thereafter France took the offensive and French armies occupied Belgium, the left bank of the Rhine and Savoy, and stirred up the populations to emulate the French in destroying the *ancien régime.* After the execution of Louis XVI., England, Holland, Spain and Sardinia formed a coalition directed against France. Russia took no part because Catherine preferred to employ her army against the Poles, who had just set up a Constitution on the French model in an endeavour to throw off the Russian yoke.

In 1793 France was invaded on all sides, but the large conscript armies that she raised were successful, first in freeing French territory, and then in occupying Belgium and the left bank of the Rhine. France then annexed all the country west of the Rhine and the Alps, which from that time were described as her natural frontiers, while Catherine took advantage of the opportunity to destroy Poland by means of the partitions of 1793 with Prussia and of 1795 with Prussia and Austria. France invaded Holland in 1795 and northern Italy and southern Germany in 1796, and the coalition was destroyed by the Treaty of Basle in 1795 with Prussia and Spain, and by that of Campo-Formio with Austria in 1797. The countries beyond the Rhine and the Alps, which were occupied by the French armies, were organized into republics on the French model; the Batavian republic arose in Holland, the Helvetian in Switzerland, the Ligurian at Genoa, the Cisalpine in Lombardy, the Roman in Rome and Parthenopean at Naples. England was left to carry on the war alone, and France prepared to invade Ireland and dispatched an expedition to Egypt in 1798.

A second coalition between England, Russia and Austria succeeded in reconquering Italy, but was checked by the defeat of the Russians in Switzerland and the failure of the English invasion of Holland (1799). The French victories over the Austrians in 1800, in Italy at Marengo, and in Germany, at Hohenlinden, compelled Austria to sign the treaty of Lunéville by which France remained mistress in Italy, and in 1802 England concluded peace with France at Amiens. (*See* FRENCH REVOLUTIONARY WARS.)

Napoleon.—Master of France since 1799 Napoleon extended his power over all neighbouring countries. He regulated the affairs of Germany in agreement with the German princes who, on the pretext of indemnifying themselves for the loss of possessions on the left bank of the Rhine, annexed the territories of the princes of the Church, of the towns and of the landed gentry, in 1803. Aroused by the colonial and maritime ambitions of Napoleon, England resumed the war in 1803. Napoleon prepared to invade England, but was forced to abandon his idea after the victory of Trafalgar, which finally assured to the British the mastery of the seas. He turned the army in readiness at Boulogne against Austria, which had just formed the third coalition with Russia and England. The surrender of the Austrian army at Ulm, and the defeat of the Austrians and Russians at Austerlitz in 1805, compelled Austria to sue for peace. The Holy Roman Empire was destroyed in 1806 when the emperor took the title of emperor of Austria; the diet was suppressed, and a great part of the German States united in a confederation of the Rhine under the protection of Napoleon; the most powerful princes, those of Bavaria, Württemberg and Saxony took the title of king.

The peace negotiations with England led to no result. Prussia, which had entered into the war on account of Hanover, was defeated at Jena in 1806 and subsequently invaded, the whole country being occupied. The Treaty of Tilsit, which was concluded in 1807 after a personal interview between Napoleon and the tsar, Alexander, deprived Prussia of her Polish provinces, which were made into a grand-duchy of Warsaw. Prussia was to remain in the occupation of the French troops until a heavy indemnity had been paid, and she was forced to reduce her army to 40,000 men. For the purpose of striking at British commerce, Napoleon decreed his Continental System (*q.v.*) to which the British Government replied with the Orders in Council. All commerce was forbidden between the British Isles and the countries under the influence of Napoleon, but nevertheless, trading relations with Great Britain continued under the guise of contraband, with the assistance of the inhabitants of these countries. The British dispatched to Copenhagen a squadron which captured the Danish fleet in 1807, and when Napoleon invaded Portugal the British navy conveyed the royal family in safety to Brazil. Napoleon, who had now become emperor, transformed the neighbouring republics into kingdoms (Holland, Italy, etc.); created in Germany the kingdom of Westphalia; conquered the kingdoms of both Naples and Spain, and gave the crowns to his brothers and brother-in-law. To make the blockade effective he annexed Holland, the shores of the North sea and the western coast of Italy, and thus the French empire extended over part of Germany and Italy.

Indifferent to the sentiment of nationality Napoleon enraged the Spaniards by giving them his brother Joseph as king, and he irritated the Germans by his repressive rule. The Spaniards took up arms against him and involved him in a war that wore out his armies; the king of Prussia chose for his ministers men who reformed the army and the civil Government; and when Austria made an appeal to the patriotism of all Germany, Napoleon declared war upon her, defeated her at Wagram in 1809, dismembered her, and in 1810 married an Austrian archduchess, who in the following year bore him a son, whom he called the king of Rome. Napoleon sought to make Paris the capital of Europe and regarded himself as the successor of Charlemagne; when he went to war with Russia he compelled Austria and Prussia to become his allies and supply him with troops; his domination

extended over the whole of Europe with the exception only of Russia, Sweden, Great Britain, Sicily, Sardinia (where the kings of Naples and Sardinia had taken refuge), Portugal and the heel of Spain. But he had used up successively two immense armies.

Fall of Napoleon.—This far-reaching empire collapsed suddenly. The army with which Napoleon invaded Russia was composed of representatives of all the European nations; at Moscow it became demoralized through too long a sojourn and was completely destroyed in 1812 during the retreat from Russia. The Prussian troops went over to the Russians, but although Napoleon commanded only a hastily recruited army, he succeeded in checking the Russo-Prussian forces in Saxony. But Austria now joined the general coalition, and on Oct. 18, 1813, the armies of the Great Powers—Great Britain, Russia, Austria and Prussia, won the victory of Leipzig, compelling the French to evacuate the whole of Germany. The allies invaded France and despite the opposition of Napoleon reached Paris in 1814. Europe was freed from the tyranny of the foreigner; France lost all her conquests.

But the influence of the revolution survived the Napoleonic empire. In all the countries which he had controlled or occupied France had destroyed the authority of the Church, abolished the privileges and rights of the nobles, and set up religious toleration and the equality of all citizens before the law. The empire had carried on the work begun by the republic, and it is in this sense that Napoleon has been called the Apostle of the Revolution. Europe emerged from this crisis transformed, the whole conditions of her political life—in Belgium, Holland, Switzerland, Spain, Italy, Germany and even Prussia—being completely changed. (*See* NAPOLEONIC CAMPAIGNS.)

THE CONCERT OF EUROPE AND THE POLICY OF INTERVENTION

The defeat of Napoleon put an end to the attempt to unite Europe under the domination of a single State. The four great Powers—England, Russia, Austria and Prussia—who in 1814 assumed the title of allies, decided the fate of Europe. The allies determined to confine France within the frontiers of 1790 and to restore the dynasty of the Bourbons. With the restored king of France they signed the Treaty of Paris of May 30, 1814, and announced their intention of establishing "a firm peace, based on a just equilibrium of strength between the Powers." The great Powers were united in their determination to keep the peace of Europe by maintaining the balance of power, and, as they alone possessed power, they agreed among themselves on the measures to be taken and imposed their decision on all the other States.

The Congress of Vienna.—The Treaty of Paris restored to the allies all the territories that had been annexed to France since 1790, as well as those of the States created by Napoleon (Belgium, Holland, the left bank of the Rhine, Italy, Germany, the grand-duchy of Warsaw) and also the kingdom of Saxony which the allies themselves had conquered in 1813. The allies summoned to Vienna a general congress of the representatives of all the States which had taken part in the war, to regulate the re-distribution of these territories (*see* VIENNA, CONGRESS OF); but in a secret article they reserved to themselves the right of determining between them the arrangements for the countries evacuated by France. They only referred to the congress the definitive settlement of Germany and Poland.

The congress thus appeared as a sovereign assembly of the representatives of all Europe, who for the first time gave a body to European unity. But in truth the congress did little more than register the decisions of the allies. The representatives of small States were not even permitted to discuss them. The discussions over the territories of the king of Saxony became so violent that the concert of the allies was temporarily broken and agreement was only restored by a compromise which gave Prussia four non-contiguous districts in place of Saxony. No question was discussed in the congress and all the arrangements were effected in the form of separate treaties between the different States and summed up under the title Final Act of the Congress of Vienna.

The deliberations had not yet reached their conclusion when Napoleon, who had escaped from Elba, restored the empire. The representatives assembled at Vienna declared, in the name of Europe, that Napoleon Bonaparte was "the enemy and disturber of the peace of the world," and undertook to preserve against all attack the order so happily re-established in Europe (March 24, 1815).

Territorial Settlement in Europe.—The territories annexed by France in Italy and Germany were restored to their former and legitimate sovereigns, but none of the States which had been suppressed in Germany in 1803 were restored. The king of Bavaria received the Palatinate on the left bank of the Rhine; Prussia took the Polish province of Posen, received as indemnity three German provinces (Saxony, Westphalia and the Rhine Province), and acquired the remainder of Swedish Pomerania. Germany was formed into a confederation of sovereign States represented by a diet. In Italy the Genoese and Venetian republics were not restored, and Genoa was annexed to the kingdom of Sardinia. Austria received the Milanais and Venice, which were united in a Lombard-Venetian kingdom, and in Germany she received the ecclesiastical domain of Salzburg. Switzerland acquired the former bishopric of Basle and a piece of Savoy; Belgium and the kingdom of Holland were united into the kingdom of the Netherlands; and Norway, which was taken away from the king of Denmark, was given to the king of Sweden. Russia and England retained their conquests; England kept Malta and Heligoland, the protectorate of the Ionian Islands, and, outside Europe, the Dutch colonies in the Cape as well as Ceylon and Mauritius, while Russia retained Finland, which she conquered from the Swedes, and Bessarabia, which she had taken from Turkey. These arrangements were made secretly by the Governments, and without consulting the peoples of the countries concerned; they were based on the claims of legitimate princes and the denial of any right on the part of the peoples to determine their own destiny.

The Holy Alliance.—The tsar Alexander wished to strengthen the political alliance between the sovereigns by one of a mystic nature, and hence arose the agreement known as the Holy Alliance (*q.v.*), by which the European monarchs undertook to regard themselves as appointed by Providence to rule the three branches of a single family. It was a pact of Christian brotherhood; but, while Louis XVIII. adhered to it, out of regard to the tsar, the British Government refused their assent, and it resulted in a mere demonstration, having no practical effect. The public, however, confused it with the Quadruple Alliance, formed in 1814, and were thus in the habit of calling the coalition of the allies against France "the Holy Alliance."

Treaties of 1815.—The events of the Hundred Days (*see* WATERLOO CAMPAIGN), determined the allies to adopt new measures in regard to France, and by the treaty of Nov. 10, 1815, they forced her to surrender her frontier fortifications, to pay an indemnity, and to submit to the occupation of a part of French territory until payment had been made. Napoleon and his family were for ever excluded from the French throne, and in certain secret articles the four allied sovereigns agreed to hold, at stated intervals, conferences for the prosecution of common interests and the examination of the means of maintaining the peace of Europe. Their ambassadors at Paris were to meet once a week to enquire into the condition of France and to give advice to the French Government; the conference was presided over by Wellington, the commander-in-chief of the allied army of occupation, who was informed by his Government that the allies had promised Louis XVIII. to uphold him by force of arms against all revolutionary movements. Thus there came into being a permanent European institution destined to furnish legitimate monarchies with an instrument for "intervention" in their internal affairs, and these measures—which were specially directed against France—stamped upon French public opinion a violent hatred of the treaties of 1815, which for half a century was to be a cause of anxiety to Europe.

Metternich.—The Vienna treaties only guaranteed the maintenance of the territorial *status quo* in Europe; but the allies felt that to maintain peace, which they conceived to be threatened by the spirit of revolution, it was necessary to uphold the internal established governmental system of the States by supporting

"legitimate" sovereigns against their subjects. Of all the allied Governments, that of Austria was the most hostile to innovations. The emperor Francis said, "My empire is an ancient edifice; if it is touched it may crumble."

Metternich, who directed the foreign policy of Austria, summed up the theory in general formulae and extended the principle to the whole of Europe. "The basis of contemporary politics," he wrote in 1817, "is and must be peace and quiet"; he regarded every "constitution" as a potential means of disorder devised by those whom we should now call "the intellectuals," and held that "the people at large dreaded the movement"; it was the rich, the civil servants, the writers, the lawyers and teachers who, with their battle cry, "the Constitution!" were really aiming at innovation and disorder. "The aim of the agitators," he wrote, "is the *overthrow* of everything by law existing; the guiding principle of kings, on the contrary, should be to *conserve* everything by law existing." This maintenance of the *status quo* is the policy known as "Metternich's system."

Liberal Movement.—Ever since 1814 the same political system had obtained throughout almost the whole of Europe; with the exception of France, the Netherlands, Switzerland, Sweden and Norway, all the European States were absolute monarchies in which the power of the throne was uncontrolled by any Constitution or elected assembly. As lands had been distributed among princes without regard to the feelings of the peoples, Europe had been divided into States irrespective of nationalities. Germany, Italy and Poland had thus been dismembered, while a single State—the Austrian empire—united under one Government many nationalities.

This system was intolerable, both to those who desired to set up a Constitution as a means to political liberty, and to those who sought to create States on a basis of nationality. These malcontents formed an opposition, henceforward called Liberal, and one which was later to be known as National. The Liberals and the Nationalists, in struggling against the same enemy, united in an attempt to destroy the system set up in 1815, and as all the European Governments were in agreement in seeking to maintain it, the opposition in each country had common interests with those in other countries and sought to act in concert with them. Since the Governments made it impossible for the oppositions to act in accordance with the law, they pursued illegal courses, by means of secret associations, murder and intrigue. (*See* CARBONARI.) Their most efficacious method was to win over officers of the armies in order to compel the Government by means of military revolts to grant Constitutions.

The Congress.—The Tsar Alexander had retained the liberal and humanitarian fancies that had at first brought him into conflict with Metternich in Germany and Italy. In order to discourage the opposition, Metternich wished to make plain to Europe the agreement of the great Powers. When Wellington declared that France could be evacuated without danger to the peace of Europe, the allies arranged the evacuation at the conference of Aix-la-Chapelle (*q.v.*) in 1818. By inviting the king of France to enter into the alliance of the great Powers and by terminating the permanent session of the ambassadors' conference in Paris, the allies put an end to the exceptional position hitherto occupied by France. But by secret convention they agreed to make common cause in the event of a revolution in France which might menace the security of her neighbours. This conference was a decisive success for Metternich; for Alexander, disquieted by the French elections in 1819, and enraged by the assassination, by a German student, of the Russian agent Kotzebue, became a convert to the policy of intervention.

For some years Metternich directed the policy of Europe. He took advantage of demonstrations on the part of German students and afterwards of four military revolts in 1820 in Spain, Portugal, Naples and Sardinia to assemble congresses, which always met on the Austrian soil, at which the great Powers took steps for intervention in the internal affairs of other States. The congress of Carlsbad in 1819 imposed on all the German States a system of police surveillance of the universities and the press; the congress of Troppau in 1820, which was subsequently transferred to Laibach, decided the intervention of the Austrian army in the Neapolitan kingdom; while the congress of Verona in 1822 determined the French armed intervention that restored absolute monarchy in Spain. The three great autocratic Powers—Austria, Prussia, Russia—signed a declaration by declaring that any European State in a condition of internal revolution should remain excluded from the concert of Europe until law and order had been restored, and they reserved to themselves the right of using force to re-establish that order. Thus there came into international law the principle of intervention, and the Governments which were united in their common battle against the revolution sought not only to maintain by force the territorial settlement of 1815, but also the autocratic form of government. They established themselves as the supreme political court of Europe for the control of international affairs. (*See* TROPPAU, CONGRESS OF; LAIBACH, CONGRESS OF; VERONA, CONGRESS OF.)

The English Policy of Non-intervention.—The policy of the English government was in direct opposition to that of the other great Powers. In 1818, at Aix-la-Chapelle, Castlereagh repudiated the idea of a consolidated alliance which would compel each State to maintain the succession and would defend the Government and internal administration of every state against attack, on the ground that "such an alliance would pre-suppose a collective Government capable of constraining all kings and nations to one code." In 1820 Castlereagh declined to adhere to the declaration of Troppau which in his view amounted to an invitation to all the states to submit to the jurisdiction of the alliance. On the occasion of French intervention in Spain (1823), Canning declared that the "alliance had been formed against the military domination of France and not for the purpose of governing the world or of superintending the internal affairs of other states"; he protested against the "system of policing Europe" and added that England "should insist on the right of nations to choose for themselves the form of government that they judged best." Thus to the principle of intervention Canning opposed non-intervention and to the ancient right of legitimate monarchies the new right of nationalities. It is true that by "nations" he meant only the State within the territorial limits established by the treaties of 1815, and it never occurred to him to recognize a right in any State to adjust its frontiers in accordance with national sentiment. Nevertheless, his formula—the right of nationalities—was to be a factor in the complete transformation of the map of Europe. (*See* LONDONDERRY, SECOND MARQUESS OF; CANNING, GEORGE.)

Weakened by the attitude of England, the European concert was broken up by revolutionary crises that arose in two countries which had not been affected by the settlement of 1815: the Spanish colonies in America and the Ottoman empire. The government of the United States set the example by recognizing the independence of the republics founded by the colonists who had revolted against Spain. (*See* MONROE DOCTRINE.) Canning refused to be a party to this recognition while at the same time he declared that any attempt at intervention on the part of France in America would be looked upon as a *casus belli;* and, in 1824, in order to open Spanish-America to British commerce, he recognized the new American republics as independent states in opposition to other Powers who wished to support the king of Spain. But the policy of intervention finally came to grief in the Greek revolt. The Ottoman empire had never been a party to the treaties of Vienna, and Europe had not guaranteed its territory; moreover, the tsar Alexander disliked the idea of forcing Christians to submit again to the yoke of the Infidel. Public opinion throughout Europe was aroused to enthusiasm on behalf of the Greeks. At first the European Governments remained neutral, but, in 1823 Canning recognized the belligerency of the Greeks. A conference summoned by Alexander offered the sultan the mediation of the Powers (1825), but without success. Nicholas I., newly on the Russian throne, entered into an agreement with England to put an end to the anarchy in Greece by an intervention to which France was also a party (1827); and the unexpected result of this policy was the battle of Navarino which led to war between Russia and Turkey, the invasion of Turkey

by the Russians in 1829 and the establishment of a small Greek kingdom.

The Crisis of 1830.—The 15 years that had elapsed since 1815 had been for the internal policy of Europe a period of repression and silence in the autocratic monarchies and of torpor in the two constitutional monarchies. In England these years were occupied by agitation for reforms and in France by discussions in the chambers. But economic prosperity brought to the fore new Liberal leaders who were ready to take office in England and France and who had formulated the theory of parliamentary government, in which the sovereign power of a constitutional monarch is transmitted to an assembly by the intermediary of responsible ministers.

The crisis began in France in the conflict between Charles X. and the chamber, and led to a Parisian insurrection against the Bourbons under cover of the tricolour. The revolution of 1830 ended in the accession of Louis Philippe who summoned the middle classes to power and accepted parliamentary government. Belgium, following the example of France, also had a revolution, the result being the creation of the kingdom of Belgium; and the same example led in Switzerland to an agitation that brought the Radicals to power in many cantons. The crisis which arose out of the agitation for electoral reform gave the British government into the hands of the Liberal party, who finally introduced into British political life their system of responsible government.

Europe was thus divided between two opposing groups, of which the one was led by the parliamentary monarchies of France and England, and the other by the three autocratic monarchies. Each of these groups sought to interfere in the internal affairs of its neighbours in order to support therein the political system which it practised itself. Thus England and France recognized the Belgian kingdom and in 1831 defended it against the army of the king of the Netherlands; they also aided the supporters of constitutional monarchy in Portugal and in Spain. Austria, on the other hand, dispatched an army to destroy the Provisional Governments that had been established in the Italian duchies and the Romagna, and, in agreement with Prussia, repressed liberal and democratic agitation in the small German States; while the tsar in 1831 crushed with a heavy hand the nationalist rising of the Poles.

The Eastern Question.—The Eastern Question (*q.v.*) brought Russia and England into opposition; for while Russia sought to obtain the paramountcy at Constantinople and to open the Dardanelles, the British Government believed that any attempt on the complete independence of the Ottoman empire would threaten the route to India. A Turkish internal crisis in 1832 brought the question to the front, for when the sultan, who was alarmed by the victory won by Mohammed Ali (*q.v.*), the pasha of Egypt, appealed for help to the tsar, the latter dispatched an army and a fleet to defend Constantinople: in the following year the sultan signed a treaty with Russia undertaking to close the Straits to the navies of other powers, thus creating a Russian protectorate in disguise.

The sovereigns of Austria, Russia and Prussia strengthened their *entente* at the interview at Münchengrätz followed by the secret treaty of Berlin (Sept.–Oct. 1833). In view of the dangers with which the order established in Europe by international law and the treaties of 1815 were threatened, they declared themselves unanimously resolved to re-affirm their conservatism as the unalterable basis of their policy, and added that every independent sovereign has the right, in cases as well of trouble within his kingdom as of dangers threatened from without, to call to his aid any other independent sovereign. This amounted to a solemn affirmation of the doctrine of intervention. Henceforth the Powers who had formed the concert of Europe were grouped into two opposing camps. Supported by a hardy public opinion in Great Britain, Palmerston led the Liberal States while Nicholas, proud of his military strength, supplanted the aged and weakened Metternich in the command of the Absolutists.

The Quadruple Alliance.—Spain and Portugal were in the throes of a war of succession between two queens who were minors, Maria of Portugal and Isabella of Spain, and their uncles, Miguel of Portugal and Don Carlos of Spain, both supporters of absolute monarchy. The Liberals took the part of the young queens and the British Government intervened in their behalf. Palmerston induced Portugal and Spain to ally themselves with England and he could not deny to France the entry into this quadruple alliance (1834); and in both countries the civil wars ended in the establishment of constitutional monarchies under the protection of England and France although the Carlists and Miguelists had the moral support of the Allies of Münchengrätz.

The Eastern Question in 1840.—It was, however, difficult to maintain an entente between England and France, seeing that the respective Governments had to reckon with the national vanity of a sensitive public, excited by memories of the old established rivalry between the two nations. Louis Philippe, on his part, wishing to be admitted into the "family of sovereigns" sought to make friends with the Continental monarchies. In Greece, Spain and Portugal, the British and French Governments each supported one of two opposing parties. The rupture could no longer be concealed when a new crisis was provoked by the Eastern Question. Mohammed Ali (*q.v.*), attacked by the sultan, once more occupied Asia Minor in 1839; and the Powers determined to intervene. But the British and French Governments were unable to agree upon the conditions to be imposed on the belligerents. The French people were enthusiastic supporters of Mohammed Ali whom they looked upon as a protégé of France. Palmerston secretly negotiated with the three other great Powers and concluded with them and the sultan the Convention of London in 1840, which delivered an ultimatum to Mohammed Ali, and France found herself isolated before a coalition of the allies of 1815. The Eastern Question had created a European crisis and Nationalist passions awoke in the middle classes and the literary world. In France there was talk of destroying the treaties of 1815 and reconquering the Rhine frontier to which the German reply was an anti-French agitation for a defence of the "German Rhine." The crisis terminated in the submission of Mohammed and in the Straits Convention (1841) by which the sultan undertook to close the straits to warships. The Russian minister, Nesselrode, congratulated himself on having re-established "the federative system of the European States on its old basis." (*See* also EASTERN QUESTION.)

France and England.—The entente between France and England was officially re-established by the Conservative Government of Peel. This was the *entente cordiale* to which expression was given by an exchange of visits between Queen Victoria and Louis Philippe (1843–45). Nevertheless the two nations continued to disagree, as was shown by the opposition of the chamber in the affair of the right of search and in the affair of the payment of an indemnity to the missionary Pritchard, at Tahiti, and by the British protests against the project of a Franco-Belgian customs union. In 1845 France and Great Britain made common cause in attempting to settle the question of the marriage of Queen Isabella of Spain and her sister the Infanta Louise. But the French and English ambassadors at Madrid, who were personal rivals, worked in a sense contrary to the instructions of their Governments. Palmerston, who had returned to the Foreign Office in 1846, complicated the question by a protest against the arbitrary Government of the Queen Regent, Christina. Louis Philippe, however, who was aiming at securing the succession to the Spanish throne for his descendants, ignored the convention of 1845 by which he had promised not to permit the marriage of his son to the infanta until the queen had been married to a Spanish Bourbon, and an heir born to the throne. The marriage of the Duc du Montpensier with the infanta was celebrated on the same day as that of the queen, and thereupon Palmerston broke off the entente with France. (*See* SPAIN.)

Liberalism and Nationalism.—Embroiled with England, Louis Philippe made common cause with the absolute monarchies. England remained isolated. Palmerston took upon himself the rôle of protector of Liberalism in Europe. He sent Lord Minto on a special mission to encourage the Italian princes to undertake reforms in their States against the wish of the Austrian

Government. For long he engaged in negotiations with the great Powers who wished to intervene in Switzerland in support of the Catholic league or *Sonderbund,* in its conflict with the Federation, and thus gained time to enable the Federal Government to end the war by destroying the *Sonderbund.* (*See* SWITZERLAND.)

During the long peace new parties arose in Europe in opposition to the existing political, national, social and ecclesiastical systems. Their agitation prepared a way for a radical change in the conditions of national life. As early as 1817 a struggle had commenced in England between the Radicals, who demanded universal suffrage, and the supporters of the existing electoral system, by which the right to vote was denied to all save the privileged classes. The first victory of this campaign, which became general throughout Europe, was won by the Radicals in some cantons in Switzerland, in 1830. Shortly after the Parisian insurgents, who had conquered the Bourbons, revived the republican traditions of 1793, and attempted, by means of insurrections, to overthrow hereditary monarchy and establish a republic. These aspirations towards political equality, which usually displayed themselves under the guise of republicanism were collectively described by the vague term "democracy." Their supporters were to be found, above all, among the youth of the great cities, and these were organized into an international party by the Italian, Mazzini (*q.v.*). He established a secret society called Young Europe, which was divided into national sections and had for its object the establishment everywhere of democratic republics.

In countries in which the sentiment of nationalism was wounded by the political system the agitation for unity or autonomy became more intense through alliance with democratic agitation. Victorious in Belgium in 1830, crushed in Poland, Italy and Germany, it reappeared in Hungary in the union between the Magyar nobles and the democratic orator Kossuth (*q.v.*); in Germany after 1840, with the connivance of the princes; in Italy, under the form of the *Risorgimento,* with the protection of the sovereigns of Sardinia and Tuscany; in Bohemia, under the leadership of Professor Phalacky; and in Croatia under the inspiration of the journalist, Gay.

The industrial revolution, which began in England in the 18th century with the growth of great industries, had brought to life, in countries where industry was highly developed, a new class of workers who had no security within the established order of society. They lived from day to day as propertyless wage-earners unattached to the soil. Philanthropists and philosophers in England and France had drafted plans of reforms which, about 1830, came to be known as "Socialism." Their doctrines were disseminated in England among the workmen in the great industries by the agitation promulgated by Robert Owen (*q.v.*) and in Chartism (*q.v.*). In France they attracted the republican secret societies who, in the tradition of Babeuf, reverted to the name of Communism and adopted a new revolutionary emblem, the red flag, which was destined to become the banner of international revolution. Socialism won converts among the German workers living in France who subsequently spread it among the workers of western Germany. The creation of the Socialist ideal had already been achieved in 1848 by the common efforts of Englishmen and Frenchmen. The latter had made their contribution mainly in the criticism of existing social institutions: ownership, inheritance, commercial competition, and by theories such as the right to work, social democracy, anarchism, the emancipation of the proletariat and progressive taxation. The English contributed practical methods of reform such as trade unions, co-operative societies, congresses of delegates, the general strike, and a labour party based on class warfare. Karl Marx, a German Jew, who was first a refugee in France and then in England, reduced this mass of theories and ideas to a scientific system which he and Frederick Engels gave to the world in the "manifesto of the Communist Party" (1848) terminating with an appeal for the union of revolutionary workmen throughout the world.

The traditional policy of the Catholic clergy had been to keep on good terms with the secular government for the sake of mutual support. About 1830 there grew up in Ireland, France and Belgium a party of "Catholic Liberals" which was condemned by the pope. In the Catholic cantons of Switzerland there arose a democratic Catholic party which recognized the supremacy of the Pope over the secular power.

WAR AND REVOLUTION

Revolutions of 1848.—A revolutionary movement of a democratic and nationalist character common to nearly all the European States completely transformed the political life of Europe. It began in Italy with a local revolution in Sicily in Jan. 1848, and after the revolution of Feb. 24 in France the movement extended throughout the whole of Europe with the exception of Russia, Spain and the Scandinavian countries. In Great Britain it amounted to little more than a Chartist demonstration and a republican agitation in Ireland. In Belgium, the Netherlands and Denmark it manifested itself in peaceful reforms of existing institutions; but democratic insurrections broke out in the capitals of the three great monarchies, Paris, Vienna and Berlin, where the Governments, inexperienced in the art of repression and rendered powerless by their fear of "the revolution"—to them a mysterious and irresistible power—did little to defend themselves. The revolution was successful in France alone; a republic and universal suffrage were established, but the quarrel between the supporters of the *république démocratique* and the partisans of *république démocratique et sociale* culminated in a workers' insurrection in June 1848. In Austria where the new ministers promised to grant constitutions, the monarchy withstood the storm, and in Prussia King Frederick William, who led the movement for the unification of Germany, hoisted the black, red and gold flag that had become the symbol of German unity. The German Governments agreed to the convocation of three constituent assemblies at Berlin, Vienna and Frankfurt by which democratic constitutions were to be drafted for Prussia, Austria and Germany. In Italy, at first, the revolution only took the form of a nationalist rising against Austria led by the king of Sardinia under Italian tricolour, the "white, red and green." The republic was proclaimed in 1849, and then only in Rome and Tuscany. Within the Austrian empire the nationalities subjected to the German Government of Vienna agitated for a national government and Hungary succeeded in organizing itself on an autonomous basis.

This upheaval seemed to indicate a redistribution of the territories of Europe. In the name of the Provisional Government in France, Lamartine declared that the treaties of 1815 were no longer valid in the eyes of the French republic, but he added that he accepted the territorial delimitations effected by those treaties. France did not lend her support to the revolutionaries in Europe.

Reaction in Europe.—The restoration had commenced even before the revolution was over and it was accomplished by the armies that had remained faithful to their respective Governments. Military repression was first employed in Paris by Cavaignac against the insurgents in June, and by Windischgrätz on June 17th against the Czechs in Prague, and later by the Austrian army in Lombardy and in Vienna; then in Berlin in December, and in 1849 by the Prussian army in Saxony and Baden. Order was only restored in Rome by French intervention, and in Hungary with the help of the Russian army. The king of Prussia, having refused the title of Emperor offered to him by the assembly, sought to achieve the unity of Germany by a union between the German princes. Austria and Russia, however, compelled him to abandon his design by the Convention of Olmütz in 1850. The immediate result of the reaction became manifest in the withdrawal of liberal democratic or nationalist concessions which had been made during the revolution: universal suffrage, liberty of the press and of assembly. Absolute monarchy was re-established in Germany, Austria and Italy, and the Governments, in alliance with the middle classes and the clergy, who were terrified by the socialist proposals, strengthened the police forces and organized a persecution of the popular press and associations which paralysed political life. In France the reaction led to the *coup d'état* against the assembly on the part of

Prince Napoleon on Dec. 2, 1851, and the re-establishment of the hereditary empire in 1852.

The restoration, however, was not complete, universal suffrage was not abolished in France; in Prussia, the Constitution of Jan. 1850, which established an elective assembly, and, in Sardinia, the Constitution of March 1848, were retained; the signorial rights were not restored in Austria.

Napoleon III.—The proclamation of the French empire was a violation of the treaties of 1815 by which the house of Bonaparte had been for ever excluded from the French throne. The great Powers recognized Napoleon III. because he re-established the monarchy in France and because he promised in a secret protocol to maintain the *status quo*. Nicholas of Russia, however, sought to address him only as "bon ami" instead of the customary "cher frère." Absolute master of France, Napoleon abandoned a policy of peace. As the enemy of the treaties of 1815 which had been directed against his own family and as the friend of the Italian patriots who were exasperated by Austrian domination, Napoleon wished to destroy the work of the allies of 1815, to expel the Austrians from Italy, and to obtain an increase of territory as a recompense. It was his desire both to help nationalities to become states and to annex territories to his empire. For this two-fold purpose he worked with the revolution, and was ready to go to war in order to rearrange the map of Europe. He knew that his ministers did not approve of his policy and so he concealed his plans and actions from them, and by means of secret agents made moves that were in opposition to the official policy of his Government.

Crimean War.—Proud of having kept Russia free from revolution, Nicholas proposed to England (Feb. 1853) a plan for the division of the Ottoman empire but encountered a decided refusal. Next, on the pretext of regulating the conflict which had arisen over the holy places in Palestine, he despatched to Constantinople a special mission for the purpose of intimidating the sultan; but the arguments of the British ambassador, Stratford Canning, decided the Turkish ministers to reject the secret treaty offered to them by the tsar, whereupon Nicholas broke off diplomatic relations with Turkey and sent troops to occupy the Rumanian principalities. The British government intervened, and Napoleon, although quite indifferent to Turkey, seized the opportunity to break the allied entente of 1815 and to conclude a treaty of alliance with England and the sultan. For the first time since 1815 the great Powers made war upon one another. The Russians, defeated by the Turks on the Danube, evacuated the principalities, and the scene of war shifted to the Crimea, where the conflict went on until the capture of Sebastopol. (*See* CRIMEAN WAR.) The Austrian Government took no part in the war, but discussed with the allies the conditions of peace to be imposed in Russia. Napoleon took advantage of the Franco-British alliance to enter into federal relations with Queen Victoria who visited him in Paris; this being the first occasion on which an English sovereign had set foot in Paris since the 15th century. The charm of the emperor's personality made a strong impression on the English queen.

Nicholas I. died in March 1855, and his son Alexander II. agreed to the terms proposed by Austria: peace was concluded in Paris by a congress of representatives of the great Powers, the sultan and the king of Sardinia who had sent troops to the Crimea. The Powers guaranteed the integrity of the Ottoman empire, and the sultan, in return, promised to introduce reforms; the Black sea was neutralized and closed to ships of war; Rumanian principalities were declared autonomous; a part of Bessarabia was restored by Russia to Moldavia; and the concert of Europe was re-established and completed by the entry of the Ottoman empire. Acting as the representative of a united Europe, the congress laid down (1856) the rules of maritime international law in time of war and forbade states to give letters of marque to privateers; this maritime declaration marks a stage in the creation of a recognized system of international law.

The congress of Paris was a personal triumph for Napoleon who had for the first time welcomed a European Congress to France. His house which had been proscribed in 1815, was restored to the society of reigning families and he saw the time was ripe for seeking to obtain the aid of one of the great Powers in the execution of his plans in Europe. He approached Russia with a promise to assist her in ameliorating the terms of the treaty of 1856; and in order to quiet the apprehensions of England, which were aroused by his friendship with Russia, confided his plans to Prince Albert in 1857. In the same year he met Alexander at Stuttgart; a project of alliance was drafted, Napoleon proposing to ally himself with Russia so long as he was not forced thereby to embroil himself with England. The interview was abortive, for while Napoleon sought allies to destroy the treaties of 1815, the European sovereigns would only negotiate with him to maintain them.

The Union of Italy.—Thus frustrated, Napoleon determined to act alone. He met Cavour, the foreign minister of Sardinia, secretly at Plombières and promised him to free Italy up to the Adriatic; in exchange he demanded Savoy and Nice. Daunted by the opposition of his ministers, his court, and the other sovereigns, Napoleon did not dare to take the initiative in making war. Victoria implored him in the name of the welfare of Europe to respect the treaties; and it was the Austrian Government which summoned Sardinia to disarm and commenced the war. The Italian war ended in the expulsion of the Austrian from Lombardy. (*See* ITALIAN WARS.) But when Prussia mobilized her army on the French frontier, Napoleon ceased operations and sought an interview with the Austrian emperor at Villa Franca where (July 1859) they arranged the terms of the peace that was subsequently signed in November at Zurich. Austria ceded Lombardy but retained Venetia—a cruel disappointment for the Italians. All the Italian States were to be united in a confederation. It appears that Napoleon did not wish for the unification of Italy, but only to establish a confederation of States on the German model.

The Provisional Governments set up in the States that had revolted against their princes in Tuscany, Parma and Modena, and against the Pope in Romagna, desired annexation to the kingdom of Sardinia. Napoleon gave way but demanded the cession of Savoy and Nice which he annexed to France, notwithstanding his promise of 1859 that he would seek no personal advantage from the war. The annexation of Nice and Savoy aroused the mistrust of Europe, and France found herself henceforth isolated. The unification of Italy was achieved by the Sicilian expedition of the republican Garibaldi (*q.v.*) and by the occupation of a part of the Papal States by the Sardinian troops. These states were now annexed to the kingdom of Sardinia and Victor Emmanuel took the title of king of Italy, after a plebiscite had revealed that the annexation had been made by the will of the people and in accordance with their right to decide their own destiny. A revolutionary principle was thus introduced into international law.

The kingdom of Italy, which had thus been formed in violation of the treaties and by revolutionary means, was condemned by the Pope and was at first recognized by England alone of all the Powers. The Liberal British cabinet had recognized the right of a people to overthrow tyrannical government, and from this time dates the permanent friendship between Italy and England. Napoleon, who feared to arouse the dislike of the French Catholics by withdrawing his troops from Rome, vainly endeavoured to reconcile the pope with the king, but his policy inspired among Italians a dislike for France who had been the opponent of Italian unity.

Bismarck.—William, who had been king of Prussia since 1861 had undertaken the task of strengthening the Prussian army, and for this purpose had engaged in a conflict with the elective Chamber, who had refused him military credits in the name of the Constitution of 1850. Having failed to find ministers who would undertake the task of governing without the support of a legal budget, William was on the point of abdicating. His son Frederick, whose wife was the daughter of Queen Victoria, was ready to acknowledge the right of the Chamber and if he had been in the place of his father he would have permitted Prussia to evolve parliamentary government on the English model. But William at last found a minister who was prepared to govern in face of the

Chamber. In 1862 Bismarck (*q.v.*) took control of the foreign policy of Prussia and immediately declared that German unity was only to be won "by blood and iron."

Poland.—The Poles who had revolted against the tsar appealed to the great Powers. England protested in the name of the treaties of 1815 and, in agreement with France and Austria, sent Russia three successive notes in 1863, in which she asked for an amnesty on their behalf and a change in the administration of Poland. Alexander was furious and threatened to make war upon Austria. Bismarck took advantage of the opportunity to sign a military convention with Russia, on Feb. 8, 1863, which had for its object a common action on the part of the Russian and Prussian armies against the Poles. Thus Prussia won the gratitude of Alexander and the benevolent neutrality of Russia during all the wars in which she was subsequently engaged.

The Danish War 1864.—The Schleswig-Holstein question (*q.v.*) which had become acute in 1848 with the revolt of the Germans in Holstein, was temporarily suspended by the Treaty of London of 1852 which guaranteed the possession of the duchies to the king of Denmark. It was re-opened when Christian IX., the heir in the female line, became king of Denmark in 1863 and was compelled by a national Danish party to annex Schleswig. Frederick of Augustenburg, of the male line, was recognized heir to the duchies by the German diet. Prussia and Austria separated themselves from the other German States, protested in the name of the Treaty of London against the annexation of Schleswig, and then made war against Denmark in 1864. The British Government proposed intervention to Napoleon, but Napoleon in return asked what support England was prepared to give to France should the latter be attacked on the Rhine. England took advantage of an armistice to assemble a conference of the Powers in London, but she was unable to obtain agreement for a plan of partitioning Schleswig, and the war ended with the cession of the duchies. Bismarck having failed to obtain them for Prussia sought to impose on the duke of Augustenburg conditions that would have rendered him a minion of Prussia, while Austria protested that the Confederation could only admit equal and independent princes.

The Austro-Prussian War.—Prussia was determined on war and Bismarck went to Biarritz to satisfy himself as to what Napoleon's attitude would be. Next he concluded a treaty of offensive alliance in 1866 with Italy. The public rupture with Austria arose from the administration of the duchies. The leading German States took the side of Austria and the rest remained neutral. War was decided with a rapidity that disconcerted all the governments of Europe by the single battle of Königgrätz. At the request of Austria Napoleon offered to mediate but he was not strong enough to frighten Prussia and was compelled to accept the peace proposals of Bismarck. By the Peace of Prague, Austria suffered no territorial loss but was compelled to give Prussia a free hand in Germany. Prussia annexed the German States lying between its western provinces and the main body of the kingdom. All the German States were united into a North German Confederation with the exception of the four south of the Main. The duchies were annexed to Prussia with the proviso that the districts north of Schleswig should be returned to Denmark if the population expressed the wish to that effect. This clause which was abrogated in 1878, was carried out in 1920.

Napoleon's Mistakes.—Bismarck had let Napoleon hope for certain territories in compensation for the aggrandisement of Prussia. Napoleon at first demanded the Bavarian lands on the left bank of the Rhine and then Belgium. Bismarck gave him nothing, but revealed these proposals in 1866 to the South German States to induce them to conclude treaties of alliance, and in 1870 he made them public so as to arouse indignation in Belgium and England against France. In 1867 Napoleon entered into negotiations with the king of the Netherlands for the purchase of the grand duchy of Luxembourg where Prussia kept a garrison in the federal fortress. Bismarck made no opposition, but on the project becoming known he made a speech in the *Reichstag* which forced the king of the Netherlands to withdraw his consent, and the grand duchy was neutralized under the collective guarantee of the Powers.

Napoleon was compelled to send troops into Italy to help the pope who had been attacked by the Garibaldians. The French, armed with the new rifle (*Chassepot*), routed the Garibaldians at Mentana (Nov. 3, 1867), and, to inspire confidence in the weapon the Government published the report of the French commander in which occurred the phrase "*Les chassepots ont fait merveille,*" while in the chamber of deputies one of the ministers, Rouher, declared that Italy should never be allowed to enter Rome. These two phrases aroused among the Italians a hatred against France which has ever since embittered the relations between the two nations.

In France, the Government sought to prevent the unity of Germany and spoke of avenging Sadowa on a Prussia that threatened her supremacy. Napoleon sought a *rapprochement* with Austria where the Ministry for Foreign Affairs had been entrusted to an enemy of Prussia, Beust, a former minister of Saxony. Napoleon proposed to Austria and to Italy an alliance which would restore Austria to her former position in Germany, and the negotiations resulted in an exchange of autograph letters between the three sovereigns in which they proclaimed their intention of holding to the idea of a triple alliance which should strengthen the peace of Europe (1869). The archduke Albert was sent to Paris, and the French General Lebrun to Vienna, to arrange a plan of campaign against Prussia (1870). The new French ministry which came into power on Jan. 2, 1870, proposed to ensure peace by a reduction of armaments, but when England transmitted the proposal to Berlin, Bismarck declared that it was incompatible with Prussian military law.

The Workers' International.—While accord between governments was broken by a succession of wars, a profound transformation in the conditions of industrial life prepared the way for a *rapprochement* of a new nature between the peoples. The progress due to science increased, in an unprecedented manner, the productivity of industry and the activity of commerce. Europe became covered with a network of railways and telegraphs which rendered communications and transport far quicker and less costly. England took the lead in this new movement and surpassed Europe in wealth, density of population and industrial experiments, and gave the example of free trade and commercial treaties which stimulated international commerce. The first international industrial exhibition was opened in London in 1851. The exhibition in London in 1862 brought representatives from French working classes and the leaders of English trade unionism together. They were of one mind in wishing to extend throughout Europe the labour association, on lines which had already been tested in England. In 1864 the International Working Men's Association (*see* INTERNATIONAL) was founded in London by an assembly attended by delegates from Britain, France, Germany, Poland, Italy, etc. The rules were drafted by Karl Marx. It was organized as a federation, and held annual congresses, generally in Switzerland or Belgium.

The Franco-German War.—The war between France and Prussia broke out suddenly as the result of an unforeseen incident. Bismarck, at the instigation of King William, worked in secret to secure the election of a Hohenzollern prince to the throne of Spain. When the scheme came to light the French minister for foreign affairs, Gramont, declared that France would never allow a Hohenzollern on the throne of Charles V. The French ambassador, Benedetti, finding nobody at Berlin able to answer him, was sent by Gramont to importune King William at Ems, where he was taking the waters, and try to make him declare that he disapproved of the candidature of the prince. When the prince's father had withdrawn his candidature, Gramont, being mistrustful of Bismarck, asked the king to promise that he would never again authorize this candidature. William refused to enter into any such engagement, and put an end to the irregular negotiation by telling Benedetti that he considered the incident was at an end. The "Ems telegram" whereby William authorized Bismarck to communicate his refusal to the press, gave him the chance to announce the refusal of the king in a shortened form in a semi-official journal, and to allow France to regard herself as having been insulted. France declared war on Prussia. The South German States joined Prussia with whom they were allied by treaty; Aus-

tria and Italy declared themselves neutral; the tsar maintained a benevolent neutrality towards Prussia.

The issue of the war was quickly decided by the three battles round Metz, which resulted in the confinement of the main French army in Metz, and the French defeat was completed by the capitulation of her last army at Sedan. The republican revolution of Sept. 4, 1870, in Paris, created the "Government of National Defence," which put Paris in a state of defence, and created armies in order to attempt to raise the siege.

Italy took advantage of the withdrawal of the French troops to occupy Rome on Sept. 20. The South German States entered into the federation which took the name of the German *Reich;* the king of Prussia was proclaimed German emperor in the palace of Versailles, Jan. 18, 1871. The war came to an end with the surrender of Paris on Jan. 28. The Peace of Frankfurt, May 10, ceded to Germany Alsace and part of Lorraine, which were annexed to the German empire, in spite of two protests on the part of the elected representatives of the country, in 1871 to the French National Assembly and in 1874 to the German *Reichstag.* (*See* FRANCO-GERMAN WAR; BISMARCK; NAPOLEON III., etc.)

The Treaty of London.—Russia took advantage of the war to declare, Oct. 31, 1870, that she no longer felt herself bound by the treaty of 1856 to observe the neutrality of the Black sea (*see* STRAITS QUESTION). England protesting that no power could, independently, rid itself of treaty engagements. But the States of Europe, feeling powerless, accepted a conference of the signatories in London (Jan. 1871), which annulled the Black sea clauses, at the same time laying down the principle that no contracting party can free itself from the engagements of a treaty without the consent of its co-signatories. This deference to a principle proved that at bottom international law depended, not on respect for treaties, but on the strength of the Powers. In order to justify Russia, Gorchakov wrote: "It would be difficult to maintain that the written law founded on respect for treaties as the basis of international relations, has preserved the same moral force it formerly possessed." Beust said in 1871: *Je ne vois plus d'Europe.*

ARMED PEACE

The Preponderance of Germany.—The concert of Europe, damaged by these wars among the great Powers, was replaced by the preponderance of the new German empire founded on an undisputed military superiority. All the European Powers remodelled their armies on the Prussian pattern by adopting universal military service; they increased their establishments and their military expenditure. The small neighbouring States, Holland, Belgium, Switzerland, Denmark, lived in constant fear of aggression. But Bismarck, who was directing the policy of Germany, did not wish to enlarge her borders; he said "Germany is surfeited." He wished to use military power, so he said in 1872, only to "maintain peace and the state of affairs created by the Treaty of Frankfurt." Because Germany could only be defeated by the collective forces of several powers, as Napoleon I. had been, Bismarck had a "coalition nightmare," as the Russian envoy, Shuvalov, told him in 1878. His policy consisted in preventing the formation of a coalition by allying Germany to the States which accepted her supremacy, and in isolating the powers which he feared to see coalescing against her. During the 20 years in which he dominated the policy of Europe, relations between the States, except in the Balkan peninsula, were reduced to interviews between the chief statesmen, to newspaper articles, to diplomatic combinations, and to agreements or defensive alliances which were in effect inoperative.

In 1866 Bismarck had secured that Prussia did not take any Austrian territory, so that no ill-feeling was left behind, but the creation of the German empire prevented Austria from having any idea of recovering her former position in Germany. The *entente cordiale* between the two countries was achieved when the old enemy of Prussia, Beust, was replaced at the Ministry of Foreign Affairs in Austria by Andrássy, the representative of the Magyars allied to Germany against the Slavs (Dec. 1871). In Russia, Alexander recalled, in a toast to William, the old friendship between the German and Russian armies, and the close relations of the two sovereigns. Italy was disquieted by Catholic demonstrations in France in favour of the temporal power of the pope, and the crown prince, Humbert, paid a visit to the emperor in Berlin (May 1872). The governments of the three empires struck by the insurrection of the Commune (*q.v.*) in Paris, wrongly ascribed to the action of the International (*q.v.*), wished to concert measures in common against the social revolution, as they had done in 1815 against the political revolution. Bismarck took advantage of this to pave the way for an entente. The interview of the three emperors at Berlin (1872) appeared to the world as a gesture of European importance. Their ministers for foreign affairs, Bismarck, Gorchakov and Andrássy, considered means whereby the peace of Europe might be maintained. It was decided that in all matters of international import, the three Powers should consult among themselves in order to work in concert. This agreement, called "the alliance of the three Emperors" (*Dreikaiserbund*) was not safeguarded by any formal treaty. It was officially defined as an alliance for the maintenance of peace without written engagements, and Bismarck declared that "Europe will recognize the new German empire as the bulwark of general peace."

The entente was broken by the rivalry of the two ministers, Bismarck and Gorchakov. Bismarck, who had become very irritable, complained that Gorchakov treated him "like a servant who does not come quickly enough when called"; he wrote to him begging him to consider him "no longer as a pupil in the art of diplomacy, but as a colleague responsible for the policy of a great empire." From that time the two rivals sought to checkmate each other. Gorchakov took advantage of the strained relations between France and Germany. The German general staff held that the law voted in France to create new battalions was a sign that France was preparing for the next war. An aide-de-camp of the emperor, Radowitz, was sent to St. Petersburg on a secret mission (Feb. 1875); rumour ran in the diplomatic world that he had come to ask if Russia would remain neutral in a war against France. An official German newspaper published an alarming article "War in Sight," April 9. The French ambassador in Russia, Gen. Le Flô, obtained an audience with Alexander and asked him if he would cover France with his sword. Alarm however soon subsided. But it began again after the *démarche* of the German ambassador in Paris, Prince Hohenlohe, who told the French minister for foreign affairs, Decazes, that his Government regarded the French armaments "as a threatening act." Decazes asked for Russian help. The general uneasiness of the diplomatic world affected the British Government. When the tsar paid a visit to William in Berlin, May 11, the British ambassador there, Odo Russell, was instructed to support the Russian ambassador at the interview between Bismarck and Gorchakov and a stop was put to the rumours of war. Gorchakov sent a circular to Russian agents dated from Berlin in which he said "*Now* peace is assured." There remained in France the impression that the tsar had protected France when she had been threatened by Germany. Bismarck explained the affair as a deliberate arrangement between Gorchakov and Gontaut-Biron by which they could pose as the saviours of peace. He retained a certain ill-feeling against Gorchakov, which put an end to the entente between Russia and Germany.

The Turkish Crisis, 1876–77.—The Russian Government was interested in the Christian peoples of Turkey in Europe, not only because they were Christians but because they were Slavs (*see* PANSLAVISM); it allowed a society to be created, called "the Society for the liberation of the Slavs," which roused the Slav subjects of the sultan in Bosnia and Bulgaria. An insurrection of the Slavs of Hercegovina (July 1875) against the extortion of Turkish officials led to the intervention of the three empires in concert. Austria was entrusted with the presentation of a note containing the reforms demanded of the Ottoman government (Dec. 31, 1875). The intervention of the Powers failed, the crisis grew more grave and resulted in a war with Montenegro, and then with Serbia (*see* SERBIA; BOSNIA; HERCEGOVINA; TURKEY; ANDRÁSSY; ANDRÁSSY NOTE), complicated by the massacre of European consuls at Salonika (May 1876) and the "Bulgarian atrocities." (*See* BULGARIA.)

The Eastern Question (*q.v.*) thus was opened again in critical circumstances for the Ottoman empire. Alexander had already

consulted with Austria at the interview of Reichstadt, July 8, 1876. Francis Joseph wished to obtain compensation for the loss of his territories in Italy by acquisitions in the Balkan peninsula; he accepted a convention allowing him compensation in Bosnia, if territorial changes took place. No European Government was prepared again to trust the promises of reform made by the Turks; control by European agents was required. Disraeli, though harassed by the agitation of Gladstone, adhered to the traditional British policy in favour of the Ottoman empire and sent a fleet to the neighbourhood of Constantinople; Alexander mobilized and forced the Turks, who had been victorious in Serbia, to grant an armistice; and England also accepted a conference of the ambassadors of the great Powers at Constantinople, which drew up a scheme of reforms. This intervention was paralysed by the promulgation of the Turkish Constitution planned by Midhat Pasha, the Turks declaring that they were contrary to the Constitution.

Alexander reaffirmed his agreement with Austria by a treaty of April 1877 and began the war. England alone protested, but added that she would only interfere to safeguard "her vital interests," the Suez canal, the Straits, Constantinople. Alexander wished to limit himself to a war north of the Balkans, but was led into an invasion which took the Russian armies within striking distance of Constantinople, when the sultan asked for peace. The British Government was divided; the queen wished for war; Derby wanted peace; Disraeli contented himself with warlike manifestations in order to appease the excited Londoners, and refused to withdraw the British fleet. The grand duke Nicholas replied by advancing his headquarters to the suburbs of Constantinople. There the Russian plenipotentiary, Ignatiev, imposed on the sultan on March 3, the Treaty of San Stefano, the latter ceding all the land occupied by the Bulgarian population in order to allow the formation of a "big Bulgaria" under the protection of Russia.

The Congress of Berlin, 1878.—Bismarck demanded that the treaty should be revised by the great Powers. Gorchakov, who did not wish the creation of a "big Bulgaria" to be called in question, proposed a conference at Berlin, in which each State should reserve full liberty of action; England demanded that the whole treaty should be submitted for revision. Alexander was short of money and needed peace; he yielded and sent Shuvalov on a special mission to Bismarck, and thence to England where he concluded a secret convention (May 30). Russia undertook to submit "the whole contents of the treaty" to a European congress. England concluded with the sultan a secret treaty (June 4) undertaking to defend the Ottoman empire in Asia Minor in exchange for the occupation of Cyprus. Bismarck had declared in the Reichstag that he merely wished to play the part of "an honest broker." The congress held at Berlin under his presidency was a tribute to the dominant position held by Germany (*see* BERLIN, CONGRESS OF). It imposed upon the sultan an Austrian occupation of Bosnia, and destroyed "big Bulgaria" by cutting it into three pieces. England made public the treaty which ceded Cyprus to her. Waddington, the French minister, protested; in order to appease him Salisbury made some allusion to Tunis. The three tributary Christian principalities of the sultan in Europe were declared to be sovereign States. Greece was promised a rectification of frontier, which did not take place until 1881.

The Austro-German Alliance, 1879.—The Russians did not receive an adequate reward for the sacrifices they had made in comparison with Austria, which, without having gone to war at all, became a Balkan power and a rival of Russia in the Balkans. Alexander recalled the fact that in 1871 William had written to him that Germany owed to him the happy issue of the war and had signed himself "Your ever grateful friend"; Gorchakov wrote to his ambassador at Vienna, Feb. 4, 1879, "It is unnecessary to say that in our eyes the alliance of the three emperors has been broken by the conduct of our two allies." William himself remained outside the conflict, and had a secret interview with Alexander (Sept. 3, 1878).

Bismarck made overtures to Austria; giving as his reason for so doing that he feared an agreement between Russia and Austria, and wished to prevent it by a close alliance with one of them; he preferred Austria because she would be willing to allow Germany to be the predominant partner, and the matter was concluded by a secret treaty in the form of an alliance for the maintenance of peace and mutual defence, should one of the two be attacked by Russia, while if the attack came from any other power, they only engaged themselves to maintain a benevolent neutrality. William maintained his friendship with Alexander, and insisted that he should be informed of the treaty. He had

MAP OF BALKAN PENINSULA SHOWING MODIFICATIONS OF FRONTIERS AGREED UPON IN THE TREATY OF BERLIN, JULY 13, 1878

The nations participating in this Treaty were Great Britain, Germany, Austria, France, Russia and Turkey. Main alterations on the treaties of Paris, 1856, and San Stefano, March 3, 1878, were: (1) Bulgaria was created an autonomous and tributary state under the sultan of Turkey; (2) the province of Eastern Rumelia was formed, to remain under military and political control of the sultan; (3) Bosnia and Herzegovina were to be occupied and governed by Austria-Hungary; (4) Montenegro and Servia were to be independent

several personal interviews with him, and Alexander drank to the health of "his best friend William" in March 1880. Bismarck, not wishing for a permanent misunderstanding entered into negotiations with the Russian Government for a defensive alliance.

The Triple Alliance, 1882.—Ill-feeling against Germany showed itself in Russia in newspaper articles favourable to France, while the idea of a Franco-Russian entente took hold of public opinion in France, which hoped to find a protector against Germany. Italy was divided between opposition to France, where the Catholics upheld the temporal power of the pope, and enmity towards Austria, the possessor of *Italia irredenta.* From the time that the republican party came into power the Italian Government drew nearer to France; and allowed the "irredentists" to make demonstrations against Austria. The establishment of a French protectorate over Tunis, 1880, made an abrupt change in Italian sentiment. The Italians held that they themselves had rights over Tunis, as the near neighbour of Sicily, where many Italians lived, and the Italian Government had protested in advance against operations in Tunis. Gambetta and Waddington had assured them that France would not undertake any course of action without coming to a preliminary agreement. Public opinion in Italy became hostile to France. The Government drew closer to Austria and King Humbert paid a visit to the emperor (Oct. 1881) during which he asked to be admitted into the defensive alliance of the two monarchies. After long negotiations Italy concluded two secret treaties of defensive alliance with Germany and Austria. If Italy were attacked by France, her allies promised to support her; and Italy undertook to support her allies in a war against two Powers. A special protocol (May 20, 1882) declared that the treaty could in no circumstances be directed against England. The Triple Alliance therefore appeared as a guarantee for

the peace of Europe and the maintenance of the *status quo*, at the same time preserving the traditional friendship between Italy and Great Britain. Rumania adhered to it by a secret treaty with Austria, the personal work of King Charles, which he communicated only to one minister (1883) and to which Germany and Italy later acceded by engaging to defend Rumania. The Triple Alliance was reduced in practice to a defensive agreement between the central European powers against the warlike intentions attributed to their neighbours, France and Russia. But it reinforced the predominance of Germany, the most powerful of the partners, and gave the impression of a compact coalition in the centre of Europe against the isolated powers outside. The Concert of Europe was replaced by the hegemony of the German empire.

Alexander III., emperor of Russia since 1881, did not love the Germans, but wished for the maintenance of peace. He gave the direction of foreign affairs to a Baltic German, de Giers, who was in favour of an entente with Germany. In reply to a telegram of congratulation he called William "this venerable friend to whom we are united by common ties of deep affection." Bismarck also hoped to avoid a breach with Russia. A secret treaty was concluded at Berlin for three years (June 11, 1881) between the "three courts" of Austria, Germany and Russia, which bound them to work in concert in matters relating to the Balkans. This treaty was kept so secret that before the publication of the Austrian secret archives it was believed that it was not concluded until 1884. At its renewal in 1884 the agreement was shown to the world by an interview of the three emperors at Skiernewicze, Sept. 1884. This treaty, which Bismarck called the "re-insurance treaty," combined the Triple Alliance with the Alliance of the three emperors. England had entered into conflict with France, who was creating a colonial empire in Africa and Indo-China, over Egypt in 1882, and with Russia over Afghanistan in 1884. Bismarck profited by these rivalries to improve the relations of Germany with the rival powers. He encouraged French enterprise in order to keep her attention occupied outside Europe. He said to the French ambassador: "I wish to see you come to the point when you will forgive Sedan as you have forgiven Waterloo"; he even suggested an alliance "to establish a kind of maritime balance of power." He caused to be held the Conference of Berlin, which settled the rules for the occupation of lands outside Europe (1884); and when the Eastern Question was re-opened by the union of Rumania and Bulgaria (*see* BULGARIA) in 1885, he supported Alexander in his refusal to recognize the union. Austria encouraged her protégé Milan, king of Serbia to embark on war with Bulgaria. On the side of France relations were strained by the manifestations of Gen. Boulanger (*q.v.*) and his followers. Frontier incidents in 1887 irritated public opinion; France and Germany both talked of war; and Bismarck increased the effectives of the army and guaranteed Germany on the side of Russia by renewing in 1887 the re-insurance treaty. The Triple Alliance treaties, originally concluded for five years were renewed and completed. Italy complained, in the words of the minister Robilant, of being "always left out in the ante-room." She obtained from Austria the assurance that she would not modify the territorial *status quo* in the East except on the principle "of reciprocal compensation for every advantage" obtained by the one or the other (May 10, 1887). The British Government accepted the suggestion of Italy to act in concert for the maintenance of the existing state of affairs in the Mediterranean and the adjoining seas.

The Franco-Russian Entente.—Bismarck had not been able to prevent the entente weakening between Germany and Russia. The idea of a *rapprochement* with France grew more popular in Russia, starting in the realm of finance; the German Government retaliated by forbidding the Reichsbank to accept as collateral the Russian State funds which were, however, accepted with alacrity by the Paris Bourse. Alexander hesitated for some time to enter into close relations with France, and had a long interview at Berlin (Nov. 1887) with Bismarck, whose fall (1890) changed the policy of Germany, while the establishment of a stable ministry in France broke down one of Alexander's objections to a *rapprochement*. William II. had taken over the direction of German policy. He refused to renew the treaty of 1887 with Russia and tried to come to an agreement with the western States. He entered into cordial relations with the Salisbury ministry and concluded a treaty whereby England gave up Heligoland in exchange for concession in East Africa (1890). He made advances to France, and his mother came to Paris to prepare the way for a *rapprochement* on the neutral ground of art. But the visit of the empress-dowager led to demonstrations on the part of Parisian nationalists and made relations worse with France (Feb. 1891). French opinion, uneasy because France was isolated in face of Germany, ardently desired to obtain the protection of Russia, whose military power she exaggerated, and Alexander at length allowed himself to be drawn into a permanent understanding. His resolution was made public by the reception of the French fleet at Kronstadt (Aug. 1891). The understanding was not completed in the form of a treaty; the tsar insisted on keeping it secret, and President Carnot could not guarantee that he would not be obliged to present it to the chambers. The two Governments considering that the maintenance of peace was bound up with the balance of power in Europe engaged themselves to act in concert on all questions which jeopardized the cause of peace, and if peace was menaced by the initiative of the Triple Alliance to use their forces simultaneously. The French Government insisted on the conclusion of a military convention. This plan was accepted by Russia and signed by the chiefs of the general staffs of the two countries in July 1892; it arranged, in case of a "defensive war," a simultaneous mobilization to be directed against Germany. Alexander left the scheme in suspense for a year; then he indicated his decision by the dispatch of the Russian fleet to France (Oct. 1893) and a telegram to the president. The convention was "definitely adopted" by the exchange of letters in Dec. 1893. This purely defensive agreement which is called "the Franco-Russian Alliance" did nothing definite but maintain the state of things established by the treaty of Frankfurt, which was also the object of the Triple Alliance; but it reassured French public opinion and it gave Europe the impression that European balance, broken by the Triple Alliance, had been restored.

Policy of William II.—Bismarck, preoccupied with the maintenance of German supremacy in Europe, had been little interested in the expansion of Germany in the rest of the globe. This old man's policy did not satisfy William, who was young, anxious to shine in the world, and to use his power. The population of Germany was growing rapidly, as were also her industries, her trade and her riches; her commercial agents, supported by her banks, sought outlets for her products throughout the whole world; her mercantile marine carried the German flag in all seas. The Germans were aware of their growing power and found themselves restricted in Europe; and they aired their need for expansion in formulas—*Mitteleuropa* (the union of all the countries of Central Europe under the economic direction of Germany) *Drang nach Osten* (expansion in the Balkan and Mohammedan East) *Colonialpolitik* (the creation of colonies outside Europe), and particularly in the creation of a navy to support German commerce and raise German prestige, all of which objects found an enthusiastic leader in the Emperor, who had, from his youth, been devoted to navigation and travel. It is this policy which has received the title of *Weltpolitik*. *Weltpolitik* brought Germany into rivalry with the two great colonial powers, England and France, for both had forestalled her by occupying almost all the available countries, and Great Britain was uncontested mistress of the seas. Thus the balance of power was upset by this new policy of expansion in the rest of the world.

Since 1889, when he had paid a visit to the sultan at Constantinople, William II. had devoted himself to promoting German influence in Turkey. A permanent mission of German officers directed in Constantinople the technical instruction of the Turkish army. Abd-ul-Hamid, feeling himself protected by Germany, freed himself from the obligations into which Turkey had entered in 1878 under the British guarantee and massacred his Armenian subjects in Asia Minor and at Constantinople (1894–96).

Nicholas II. who had ascended the Russian throne in 1894 and who lacked strength of character, fell under the influence of Wil-

liam II. and entered into an intimate correspondence with him which was published after the Russian Revolution. William wished to take advantage of this to bring together under his influence the two opposing groups of States into which Europe was divided—the Triple Alliance and the Franco-Russian Alliance. He induced Nicholas to intervene in the Far East where Japan had just defeated China, and out of regard for the tsar, the French Government joined with Germany and Russia to enforce the annulment of the treaty concluded by Japan with China (1895). The tsar then induced the French Government to add French ships to the foreign squadrons attending the celebration of the official opening of the Kiel canal. Further, William sought to take advantage of a conflict which arose between England and France over the district of the upper Nile, and since 1894 had suggested to France that she should make a united protest with him against the treaty concluded between Great Britain and the Congo Free State. After the Jameson raid on the Transvaal (*q.v.*) and the dispatch of his famous telegram to President Kruger, the kaiser, with a view to limiting "the insatiable appetite of England," proposed to France a treaty by which Germany and France should mutually guarantee each other's territories. But the French Government repelled the suggestion, seeing that would have been interpreted as an assent to the annexation of Alsace; for French public opinion, although it was strongly opposed to war, had never accepted the annexation of Alsace which had been carried out against the wishes of the inhabitants.

The Cretan massacres of 1897 were stopped by the landing of marines from the ships of the European States with the exception of Germany who refused to take part in an intervention that resulted in the establishment of an autonomous Christian Government in Crete. The war which followed between Greece and Turkey rapidly ended in a resounding victory for the Turkish army whose success was ascribed to the work of its German instructors. The kaiser undertook a triumphal journey in Syria in order to reveal to the world the extent of German influence in the East, and at Damascus announced himself as "the friend of 300,000,000 Mohammedans" (1898).

Owing to her preoccupations in the Far East Russia seemed to have lost interest in the Balkan peninsula; Austria took advantage of this to establish her preponderance there. In May 1895 Austria concluded an understanding with Russia for the purpose of maintaining the Balkan *status quo*, Russia reserving for further examination the future projects of Austria in Bosnia and Albania; in 1896 the secret treaty between Austria and Rumania was renewed, and about the same time Serbia, which was governed by the Obrenovitch dynasty, delivered up the kingdom to Austrian financiers and behaved as the protégé of Austria. It became the habit of Austrian diplomacy to treat Serbia more as an Austrian province than as a sovereign State, and it was this conception that underlay the Austrian ultimatum in 1914. The prince of Bulgaria, Ferdinand of Coburg, a Catholic, and formerly an officer in the Austrian army, had reconciled himself with the tsar by inviting him to be godfather to his son Boris, but at the same time his relations with the Viennese Government were more intimate than with Russia. Austria and Russia were moving towards a partition of the Balkan peninsula into two spheres of influence; and the Russian general Kuropatkin, who was sent on a special mission to Vienna, even proposed that a line should be drawn from north to south and that the Russian sphere of influence should lie to the east and the Austrian to the west. In reality the whole peninsula had become an Austrian sphere of influence.

Armed Peace.—Russia simultaneously made known her entente with France by an exchange of visits between the imperial family and the president of the republic, and her understanding with Germany by an exchange of visits between the tsar and the kaiser (1896–97). Italy announced that she interpreted alliance as a "pacific act which permitted to the allies the most friendly relations with the other Powers." The Italian crown prince married the daughter of the prince of Montenegro, who was a protégé of Russia, and Italy signed with France an agreement concerning Tunis and her fleet collaborated with the French fleet in Crete. All these alliances and *rapprochements* seemed to assure peace in Europe; and all the governments protested their devotion to peace but not one had any confidence in the assurances of the others, seeing in the pacific declarations of his neighbour only a cloak to conceal offensive designs. No nation felt secure. The war of 1870 had revealed that it was not enough to wait until war began in order to place armies in motion. Mobilization had become so rapid and the advantage to be gained from taking the offensive so overwhelming that every Government felt it its duty to secure the advantage of the offensive by keeping its army always ready for an immediate war. Thus the effective strength of the armies in time of peace came to equal their former strength on a war footing. Moreover, the rapid progress that had been made in military technique compelled each State, in order not to be inferior to the others, to renew constantly its equipment and artillery and to increase its fighting strength. Thus the military budgets rose swiftly higher and higher. The efforts of the International League of Peace on behalf of arbitration (*q.v.*) produced no effect on public opinion except in the United States and Scandinavia; the great Powers remained indifferent. Europe lived under "an armed peace," or peace with all the military and financial burdens common to war, and lacking all sense of security.

The Hague Conference 1899.—Nicholas II., who had been impressed by *War,* the work of a Russian financier, J. von Bloch, and whose Government was struggling with the military expenses of the operations in Asia, sought to reduce expenditure by obtaining a concerted action among the powers for a reduction of armaments. Russia invited all the States to send representatives to a Conference at The Hague to consider the means of effecting this, and the project was welcomed by public opinion which gave The Hague Conference (*q.v.*) the name of "Peace Conference." It did not obtain any limitation of armaments, but it secured three international conventions on the conduct of war on land and sea, and on voluntary arbitration between States. A permanent Court of International Justice was established at The Hague and the principle was propounded that any State had the right to offer its mediation or good offices to States in disagreement with one another. For the first time an international assembly representative of the governments of the world, met to discuss an abstract question of general interest, and in a modest form they created the first permanent international institution for the purpose, no longer merely of regulating the re-distribution of territory in accordance with the balance of power, but also of making an end to disputes by the application of international law. It was the embryo of the association of States which the French delegate, Leon Bourgeois, had already named a "Society."

Change in British Policy.—Great Britain had for long maintained herself in a position of "splendid isolation." Her relations with France had been strained by conflicts that arose between officers and agents of the two countries in all parts of the world in which they were rivals; in Indo-China where the conflict with Siam was only settled by the treaty of 1896; in western Africa over the Niger (*see* AFRICA); and above all in Egypt where the Marchand expedition on reaching Fashoda in 1898 came into conflict with the British. The tension relaxed when the coalition of the Left came into power in France, and Delcassé, who was foreign minister for four years, worked to achieve an understanding with England. With Germany, on the other hand, British relations became strained when William in agreement with his minister of marine, Admiral von Tirpitz, sought to create a navy, and the Reichstag voted credits to carry out a naval programme intended to double the strength of the German fleet (1900).

The second Boer war brought the isolation of England into sharp relief. Germany, Russia and France planned a common intervention to end the war, but did not dare to act. William II. laid aside his former policy, sought to achieve an understanding with England by forbidding German officers to take service with the Boers, and by paying a visit to London where he had an interview with Joseph Chamberlain, then secretary of State for the Colonies. In a speech at Leicester Chamberlain adopted a popular theory and proposed a "new Triple Alliance" between the three Teutonic peoples—Germans, English and Americans (Nov. 1899) and William II. refused to receive President Kruger when he

came to Europe to ask help. But the German press remained hostile to England. The new Chancellor, Prince Bülow, a disciple of Bismarck, believed that an understanding with England would prevent Germany from creating an independent navy, and preferred to retain his liberty to build a fleet against the British fleet, merely taking care to avoid a rupture during "the dangerous period of construction." Baron von Holstein, who was director of political affairs in the Ministry for Foreign Affairs, exercised an occult influence on the policy of Germany and distrusted England. British policy was based upon the principle that Great Britain, seeing that she was unable to feed her population except with the help of imports, must of necessity maintain her maritime supremacy; and this was the meaning of the formula of the "two power standard." The British Government never feared an invasion of England by the German army, a prospect that inspired popular anxiety in England; but it did fear that in a grave conflict with Germany the existence of a powerful German fleet might compel England to give way. The memorandum which was presented with the estimates for the construction of the German fleet said that this fleet should be so strong that "even for the greatest of all maritime powers, a war with it would imply the imperilment of its own supremacy." But by becoming a great naval Power Germany inevitably risked coming into conflict with Great Britain in all parts of the world in which British commerce and policy were deeply involved—Egypt, Persia, India—and should Germany be able to obtain the alliance of other maritime Powers the resulting coalition would threaten the maritime supremacy on which the British empire depended.

English supporters of a German alliance warned the German Government that England did not desire to remain isolated, and that if she was unable to obtain the alliance of Germany, she must seek other allies. But the Germans did not believe in the possibility of a real friendship between "the whale and the bear" (England and Russia) and they feared that England would use Germany for a war against Russia from which England would derive the profit. Abandoning the idea of a German alliance, England allied herself with Japan in 1902 (*see* ANGLO-JAPANESE ALLIANCE).

Queen Victoria's personal sympathies had resulted in strained relations with France, but Edward VII. was in sympathy with France, where he had often stayed as prince of Wales, and he mistrusted his nephew William II. He prepared the way for a reversal of British policy by an understanding with France. He visited the president of the republic in Paris where he was acclaimed by the crowd in May 1901. And at the same time Italy, the enduring friend of England, officially came closer to France. Victor Emmanuel who had been king since 1900, was less attached than his father, King Humbert, had been to the Triple Alliance. Italy had already obtained in 1891 an engagement on the part of her allies regarding Tripolitania, and in 1900 another "in favour of Albanian autonomy." A secret understanding with France (Dec. 1900) guaranteed complete liberty of action to her in Tripolitania. Then, before renewing the Triple Alliance treaty, Italy announced officially that it did not contain any engagement to take part in a war of aggression against France (1901), and Bülow, in order to induce the Reichstag to accept the attitude of Italy, employed a famous simile in saying "In a happy marriage the husband does not make a scene if his wife now and then dances a waltz with a stranger."

The entente between England and France was concluded in the form of a convention (April 18, 1904) to which was appended a number of declarations settling all the questions outstanding between the two states. Of these the principal concerned Egypt, which France abandoned to England, and Morocco in which England professed herself disinterested. Thus ended the long rivalry between England and France, and the balance of power in Europe was once again restored by the Anglo-French entente to which was added the Franco-Russian Alliance.

While the Powers that had hitherto been isolated were thus cementing an entente, the kaiser experienced a series of reverses that irritated German public opinion. The attempt made by Russia, Germany, France and England, to establish colonies in China under the guise of long-termed concessions and to partition China into spheres of influence, led to the national rising of the Boxers, which was repressed by an international expedition in 1900, after which William found himself compelled to abandon his ambitions in China. The submission of the Boers in South Africa (*see* SOUTH AFRICAN WAR) was a defeat for Germany, and in Venezuela, where William had dispatched a squadron to prepare the way for a German penetration of Latin America, his attempt was frustrated through the intervention of the United States. Again, the concession of the Baghdad railway to a German company was rendered nugatory by the refusal of France and England to invest the necessary capital.

Decline of Russia.—The rising of the Christian Slavs of Macedonia (*q.v.*) with the help of Bulgarian insurgent organizations, forced Austria and Russia to take common action, and their ministers hastily drew up a note to the sultan in which they demanded the establishment in Macedonia of a national police force under the command of European officers (1903). Germany refused to be a party to these proceedings, but Russia and Austria, who had hitherto been sole mistresses, were forced to share the command and control of this force with England, France and Italy.

In the Far East, Russia, who had attempted to occupy Korea, was checked by Japan (Feb. 1904) and after a series of naval and military defeats was compelled to sign a peace which ended her Far Eastern ambitions (1905). This disaster was followed by a revolution in Russia which weakened her military power and crippled her foreign policy. William profited by the opportunity to increase his influence over Nicholas and to detach him from the French alliance: "It is certain," the kaiser wrote, "that France wishes to remain neutral and even to give diplomatic aid to England; her policy gives the English a brutal confidence." He urged Nicholas to make use of the Mohammedans—"a trump card in our hand"—for the purpose of ending "British insolence."

The Second International.—Powerless in the face of the great development in the art of peace surveillance and in the equipment of troops, the revolutionaries adopted a new means for furthering their projects. There grew up in all European States Socialist parties, recruited especially from the ranks of the workers and organized on the model of the German Socialist Party which was the strongest and most disciplined in Europe. They reconstituted the International Association of Working Men and this "Second International" to which the British Labour Party gave their support, held eight international congresses in different European cities to determine doctrine and organize a common policy. The sixth international congress at Amsterdam in 1904, acting under German influence, compelled the Socialist parties to transform themselves into sections of the workers' international and to follow a common policy "founded on the Marxian principles of the class struggle, with the object, not of obtaining reforms, but of achieving the social revolution." By this decision the Socialist parties were forbidden to co-operate with bourgeois democratic parties, and were reduced to the position of Doctrinaire opposition.

The trade unions which had been established after the English model and which were inspired by Socialist beliefs were united in each country into confederations, and they founded an international federation of trade unions for co-ordinating the workers of Europe in their conflicts with their employers. These two international organizations not only created among European peoples a bond of a new kind; they intervened in foreign policy by endeavouring to compel the Governments to work for peace.

The Moroccan Crisis.—By the Convention of 1904, England in granting France a free hand in Morocco had left Tangiers under an international administration. France had at that time contemplated only a policy of peaceful penetration. But inevitable conflicts arose with the warlike population of fanatical Mohammedans, enraged by the presence of infidels, and finally turned into a regular military campaign. Lest her good faith should be suspect, England was forced to support France. The German Government had been advised by the French government that conventions had been concluded with England and Spain, but no

official notification had been sent it, and when Russia, weakened by her defeats in Asia, became incapable of giving aid to France, Bülow declared in the Reichstag that he was forced to oppose French policy in view of the economic interests of Germany in Morocco, and at the same time William landed at Tangier for the purpose of visiting the sultan "in his capacity as an independent sovereign" (March 31, 1905). Bülow demanded an international conference over Moroccan affairs, while Delcassé preferred to accept the proposal of the British Government to enter into an alliance for the purpose of common military operations. The French cabinet, however, declined to follow Delcassé, whose resignation was hailed in Germany as a victory (June 12, 1905).

William, who was sailing on the Russian coast, received Nicholas on board his yacht and took advantage of the absence of his principal adviser to induce him to sign with him a secret treaty for an offensive alliance directed against England (Treaty of Björkö, July 1905). When Nicholas wished to inform France, William forbade it. "Only the absolute certainty," he said, "that we are both bound by a treaty of mutual assistance will induce France to bring pressure to bear on England." The Russian ministers did not learn of the existence of the treaty until Germany demanded they should seek to make France a party to it; they thereupon declared it null and void.

The unity of the Triple Alliance was threatened by the policy pursued by Austria towards Italy. The chief of the Austrian imperial general staff, Field Marshal Conrad von Hotzendorf, whose patron was the Austrian heir presumptive, the Archduke Francis Ferdinand, obtained extraordinary credits for the purpose of building fortresses on the Italian frontier, in order, as he put it, "to enable the army to win early victories outside the kingdom" (1904). But the two pacifically inclined ministers for foreign affairs, Visconti-Venosta in Italy and Goluchowski in Austria, prevented an outbreak of war (1905–06). In Serbia Austrian policy suffered a severe reverse when the Obrenovitch dynasty, which was under Austrian influence, was overthrown by an officer's conspiracy and replaced by Peter Karageorgevitch who placed the reins of power in the hands of the Radical-Nationalist party that was inimical to Austria.

The conference (*see* MOROCCO and ALGECIRAS) that had been sought by Germany did not turn out in accordance with her hopes. She was unable to prevent France from obtaining a privileged position in regard to the harbour police and the Bank of Morocco and even Italy, following the English example, voted against the German propositions. Austria alone gave her support. The conference strengthened the union between the Entente Powers and exposed the weakness of the Triple Alliance. German public opinion was enraged and William II. indulged his bad temper at the expense of Austria—whom he congratulated on having played at Algeciras the part of a "brilliant second."

Disturbed by these conflicts the European Governments sought to reassure public opinion by means of pacific manifestations. An international conference at the Hague, which met at the invitation of the president of the United States, failed to bring about a limitation of armaments; but it perfected the conventions that had been concluded in 1899 and discussed the principle of compulsory arbitration, determined to draw up a list of permanent arbitrators, and established an international bureau.

The Triple Entente.—The grouping of the three great Powers in opposition to the Triple Alliance was completed by the conclusion between Russia and England of three conventions which settled their differences in Persia, Afghanistan and Tibet (August 1907). The understanding between England, Russia and France did not take the form of a treaty of alliance; for that would have been inacceptable to the British cabinet; but it was known as the Triple Entente. This union between the three Powers that Bismarck had kept in isolation restored the balance of power in Europe and made an end to German preponderance. In consequence, German public opinion was influenced against Edward VII. whom it accused of having planned the "encirclement" of Germany.

For the purpose of counteracting this impression a friendly interview was arranged between the kaiser and Edward VII., who was on his way to Marienbad, and the kaiser then went to England, where he had conversations with the British ministers (1907); but the German Government refused to agree to the British suggestions and the kaiser, in an interview published in the *Daily Telegraph* in 1908, expressed his regret that his sympathy for England was not shared by the German nation. This statement aroused a burst of anger against him in Germany which revealed the hatred of the Germans for England. In June 1908 the Anglo-Russian entente was confirmed by the visit of Edward VII., to the tsar at Reval.

The Balkan Crisis.—In 1908 the peace of Europe was disturbed by one of the periodical crises in the Balkan peninsula. Baron (later Count) von Aehrenthal, who had lately become Austro-Hungarian minister for foreign affairs, sought to regain Austria's former prestige by the pursuit of a policy independent of Germany. He entered into negotiations with Isvolsky, the Russian minister for foreign affairs, over the question of Macedonian reform; and later, giving up the idea of reform, he concluded a secret understanding with the sultan for the concession of a line of railway joining Bosnia to the Aegean (Jan. 1908).

Within the Ottoman empire the Macedonian insurgents allied themselves with the Young Turk Committee of Union and Progress, which had been secretly organized at Salonika, and forced Abd-ul-Hamid to accept the Constitution of 1876 (July 16, 1908). Hailed with equal enthusiasm both by the Mohammedans and the Christians, this revolution was looked upon in Europe as a victory for modern liberal ideas and the European States withdrew their officers from Macedonia and abandoned the system of control. But in truth, the only modern element in the Young Turk programme was a feeling of national pride; they desired to re-establish the unity of the Turkish empire by welding all the inhabitants into a Turkish nation. They wished to give seats in the Ottoman parliament to representatives of the autonomous districts of Bulgaria, Bosnia, and Crete. Thereupon Ferdinand of Bulgaria entered into an understanding with the Austrian Government for the purpose of rendering Bulgaria and Bosnia independent of the Turkish empire. Aehrenthal had an interview with Isvolsky and made known to him his project, at the same time promising to await a favourable opportunity and giving Isvolsky grounds for hoping that Austria would lend her support in opening the Straits to Russia.

All of a sudden Europe was startled by the news of the declaration of Bulgarian independence (Oct. 5), and on the following day the further news that the emperor of Austria had declared his sovereignty over Bosnia. These two declarations were violations of the Treaty of Berlin and the Russian Government demanded the assembling of a conference of the Powers signatory to that treaty, who alone had the right to authorize any alteration in its provisions. Serbia demanded autonomy for Bosnia. Aehrenthal, who was known in Austria as "the Austrian Bismarck," applied the theory of a *Realpolitik* founded on contempt for international law. He claimed that the matter was one that concerned only the sultan in his capacity as sovereign of Bosnia and that it could be settled with him alone. Austria mobilized against Serbia.

Austria and Germany were well aware that Russia was too weak to support Serbia in making war but William II. was annoyed at Aehrenthal's action because it risked giving the "signal for plundering" the Ottoman empire, which William regarded as being under his own protection. Bülow, however, calculated that Germany could not afford to dispense with Austria and he did not wish to enter any conference in which Germany would find herself in the minority as at Algeciras. Hence he induced Turkey to negotiate with Austria; and Russia renounced her support to Serbia but to retain her influence in the Balkans, gained the friendship of Bulgaria by according to Prince Ferdinand the royal title of tsar and by contributing to bring about the conclusion of an agreement with the Turkish Government. Dissatisfied with the personal policy of Aehrenthal the German Government took the initiative in making a decisive démarche. The German ambassador, Count Pourtalès, presented a peremptory demand to Russia to accept the abrogation of the article in the Treaty of Berlin relative to Bosnia. Russia gave way and agreed to the new arrangement. Thus Ger-

many achieved a diplomatic victory by seeming to have imposed her will upon Russia and to have established the supremacy of her ally, Austria, in the Balkans. Isvolsky nursed a desire for revenge, and carried it with him to Paris when he was appointed ambassador to France. Italy was annoyed that her consent had never been asked to the committal of an act that disturbed the balance of power in the Adriatic. Aehrenthal seems to have understood the danger implied in the discontent in Italy; for he induced the emperor to dismiss Conrad, who was the avowed enemy of Italy, as chief of the imperial general staff.

The Agadir Crisis.—France had extended her influence in Morocco by repressing acts of violence by the native population. Public opinion in Germany which was already discontented, was further exasperated at the dispatch of a French expedition to Fez in 1911 for the purpose of repressing the Mohammedan insurrection against the sultan. The German Government claimed that the occupation of Fez was a breach of the Algeciras agreement and announced that Germany resumed her liberty of action. She planned an intervention in the southern district of Morocco (the Sous region) where the authority of the sultan was not recognized, and despatched a gun-boat to Agadir to show that while she was not engaging in a naval operation she wished to indicate her determination to compel France to negotiate. The French Government, which was greatly disquieted, persuaded Great Britain to make a public announcement of its intention to support France and this was done in a speech delivered by Lloyd George.

The dispute was settled after negotiations in Berlin by Germany authorizing France to establish a protectorate over Morocco while Germany received in compensation a portion of French Congo. The compromise failed to satisfy French public opinion, and inflamed the Germans, who blamed their Government for having failed to use the growing power of Germany to obtain for her a place in the world in proportion to her importance.

England and Germany.—William II., together with the chancellor, Bethmann-Hollweg, a man of peaceful disposition who had succeeded Bülow in 1909, worked to establish an understanding with England. Germany was prepared to interrupt her naval programme to allay British anxiety, and sought to assure herself of British neutrality by a reciprocal engagement in which the two States should undertake not to attack each other in event of war. Negotiations, which had been interrupted by the Agadir crisis, were resumed in Feb. 1912, when Lord Haldane, the British minister for war, was sent to Berlin where he discussed with Bethmann-Hollweg the draft convention on these points. The German secretary of state for the navy, Admiral von Tirpitz, refused the suggestion of a "naval holiday" between the two countries, and the idea of a neutrality pact also came to nothing; for the British Government proposed to undertake to remain neutral only if Germany was attacked, whereas the German Government demanded this neutrality should it declare war in consequence of its treaty engagement as a member of the Triple Alliance, and thus would have prevented Great Britain from coming to the help of France. The naval experts of France and Great Britain came to an understanding over the distribution of their navies, and it was arranged that the bulk of the British fleet, which was scattered over the Atlantic and Mediterranean should be concentrated in the North sea, while the bulk of the French fleet, leaving the defence of the Channel to England, would be in the Mediterranean. The desire, however, for good relations between Germany and England continued to show itself in the speeches of the leaders of the British Labour Party and in the good relations that existed between British statesmen and Prince Lichnovsky, the new German ambassador. The negotiations over the Baghdad railway (*q.v.*) and the Portuguese colonies in Africa were on the point of success at the moment when war was declared in 1914. Sir Edward (Lord) Grey, the foreign secretary of the Liberal minister, hoped to settle these difficulties by the frank exchange of ideas, and to prevent a collision between the two groups of Powers. The Germans were eager for a *rapprochement* with England, in order to secure her neutrality in the event of war against France for as long as was necessary to assure them decisive victory.

The Balkan Wars.—The crisis from which the ultimate catastrophe of Europe was to arise was born in that cradle of crises, the Ottoman empire. It began in Africa, where Italy, by means of a succession of agreements had obtained for herself a free hand in Tripolitania. Then, she suddenly went to war without advising her allies, occupied Tripolitania and proclaimed its annexation to Italy in 1911. Austrian opposition prevented her taking operations against Turkey in the Aegean. This Italo-Turkish war weakened Turkey and impaired the relations between Italy and Austria.

The Balkan nationalities profited by the war to bring about the dismemberment of European Turkey, while Russia took the opportunity to re-establish her influence over the Balkan peoples. In great secrecy Bulgaria signed, first with Serbia and then with Greece (March–May 1912), treaties and military conventions that settled the division among them of the lands they were about to conquer; they communicated the treaties to Russia and undertook that in event of disagreement among themselves they would submit to the arbitration of the tsar. This alliance completely upset the balance of power in the Balkans.

The Italo-Turkish war was ended by the Treaty of Lausanne (Oct. 18, 1912). The Balkan states determined to surprise Turkey before she had time to prepare herself, and despatched an ultimatum to the sultan in which they demanded autonomy for Macedonia. Then for the first time the small Balkan States, unaided, made war against the Ottoman empire. The Austrian Government, which had been apprised of their plans, offered no opposition because it counted on the victory of the Turks. But the Balkan allies routed the Turkish army and occupied Thrace, Macedonia, and Epirus; the Bulgarians, indeed, were only checked within sight of Constantinople. The victory of the Balkan States was felt in Europe as a Russian success, a check for Germany, the protector of the Ottoman empire, and a defeat for Austria—inasmuch as the Serbian victory, which was hailed by demonstrations on the part of the Slav subjects of Austria, encouraged the nationalist movement of the southern Slavs against Austria. The Austrians, determined to prevent the Serbs from reaching the Adriatic, threatened Serbia with war and forced her to evacuate Durazzo. The great Powers, anxious to avoid war at all costs, assembled a conference of ambassadors in London and created an Albanian State under the rule of the German Prince of Wied.

Excluded from the Adriatic the Serbs sought an outlet to the sea at Salonika and demanded that part of Macedonia which bordered on the territory conquered by the Greeks. Ferdinand of Bulgaria, however, required this country to maintain contact with Albania, and when Serbia appealed to the arbitration of the tsar, Ferdinand mistrusted Nicholas, who was disposed to favour the Serbs. To gain the advantages of offensive action Ferdinand ordered the Bulgarian army to make a surprise attack on the allied Serbians and Greeks. This resulted in the rout of the former, the invasion of Bulgaria—in which Rumania took part and the Peace of Bucharest which was disastrous to Bulgaria. The unity of the Balkan States was destroyed in this second war which assisted the revival of Austrian influence in Bulgaria.

The Balkan wars, which had taken place in spite of all efforts to preserve peace, awoke throughout Europe the fear of a general European war. The German Government announced in the Reichstag that the disturbance of the equilibrium in the Balkans, where Germany was bound to support Austria, involved an augmentation of its military strength. A huge credit for the war-chest was accordingly voted, whereupon the French Government replied by voting a three years' service. Austria looked upon Serbia as a permanent source of danger to the Habsburg monarchy and desired to reduce it to the condition of a small State dependent upon her; in 1913 she communicated to Italy a plan for the invasion of Serbia to which the Italian Government refused to be a party. The Russian Government wished to consolidate its newly regained influence in the Balkans by supporting Serbia, and it had resumed its plans for expansion towards Constantinople and the Straits. Russia moreover was alarmed at the extent of German influence over the Young Turks and protested when the German general, Liman von Sanders, was given the command of the Turkish army

corps at Constantinople. Isvolsky, who was Russian ambassador in Paris, desiring to avenge himself for his defeat in 1908, established intimate relations with Poincaré, president of the republic since 1913, who appointed as ambassador to St. Petersburg that enemy of Germany, Delcassé. Feeling themselves assured of the support of France the Russian Government reviewed the situation in Feb. 1913 and, confident that their plans with regard to Constantinople could not be realized except after a European war, they ordered the preparation of plans for a landing of troops on the Bosporus. The danger came from Austro-Russian rivalry and in the enmity between the French and German nationalists. It was in vain that the democratic parties endeavoured to avert a rupture by manifestations of Franco-German *rapprochement*, by the socialist conference at Basle and the inter-parliamentary conference at Berne. But the tension was maintained by incidents on the French frontier and by the centenary celebrations of the battle of Leipzig in Oct. 1913.

ORIGINS OF THE WORLD WAR

The Serajevo Crime.—Peace was broken by an event that occurred in the Balkan territory of Austria—the murder of the heir to the Austrian throne, the archduke Francis Ferdinand, at Serajevo, the capital of Bosnia. The murderers were Bosnian Slavs, and subjects of Austria; the weapons they used came from a Serbian arsenal. Long afterwards it became known that these weapons had been supplied to the assassins by a Serbian officer, a member of a secret society known as the Black Hand, which was led by an officer of the Serbian staff named Dimitrievič. The Serbs were inspired by hatred for Austria, who persecuted its orthodox Serb subjects and stood in the way of Serbian national unity. But the report made to the Austrian Government by Wiesner on July 13, 1914, rejected the idea of any complicity in the crime on the part of the Serbian Government.

The Austrian Government was convinced that the independence of the kingdom of Serbia imperilled the existence of the Austro-Hungarian empire, because it provoked the Slav subjects of the emperor to break away from the empire. Austria had already determined to render Serbia harmless by making it again dependent upon her, and she had instituted diplomatic action to isolate her by means of the Balkan league. The murder of the Archduke, however, opened the way for military action and Berchtold, the minister for foreign affairs, announced to Count Tisza, the Hungarian minister president, Austria's intention "to take advantage of the crime" to "settle its account with Serbia." Tisza advised that Austria should await a more favourable time and act only after she had achieved an agreement with Rumania and Bulgaria. The Austrian Government before entering into a war that might lead to Russian intervention wished to assure itself of the support of Germany and Count Hoyos was sent to Berlin with a letter from the emperor which was handed to the kaiser on July 5 by the Ambassador Count Szogeny.

The kaiser replied that Austria could count on "the complete support of Germany"; Russia was not ready for war and would think twice before taking up arms. The kaiser himself made preparations for leaving on the 7th for his annual holiday in the North Sea. He did not hold, as has been thought, a royal council at Potsdam, but confined himself to having an *informal* conversation with the chancellor Bethmann-Hollweg and interviews with certain officers whom he warned to take dispositions, although he did not believe Russia would go to war.

Without giving a definite reply Bethmann-Hollweg told Szogeny and Hoyos that in the relations between Austria and Serbia it was for Austria to judge as to what should be done, and he did not seek to learn the intentions of the Austrian Government (the Bavarian *chargé d'affaires* in Berlin said, on July 18, that Germany had given Austria "a free hand"). The two governments agreed that Italy should not be informed but the Germans advised Austria that it would be necessary to compensate Italy for any advantage which Austria might gain in the Balkans.

The Austrian council of ministers proposed at Vienna, on July 7, to impose on Serbia conditions so inacceptable as to lead only to war; Tisza opposed this policy and threatened to resign. The decision was taken on July 14. The chief of the general staff, Conrad, declared that from a military point of view "all temporizing" would be dangerous. The minister for foreign affairs, Count Berchtold, considered that from a political point of view this decision would be damaging to the prestige of Austria which Germany would tax with weakness. Another council held on the 19th agreed to the terms of the ultimatum to Serbia and discussed the results to be expected from the war. Serbia was to be placed in a state of dependence on the monarchy by a military convention; its dynasty was to be expelled; its territory apportioned between the other Balkan States. On July 21 the emperor gave his approval to the note, but it was determined to delay its dispatch until President Poincaré had left St. Petersburg. The whole operation was conducted in great secrecy. The German Government had adopted a passive attitude and had not made any attempt to induce Austria to modify the terms of the note. Europe received the impression that the Austrian and German Governments had come to an understanding to lull the suspicions of the other governments and take them by surprise.

The Ultimatum to Serbia.—The German Government had refrained from any participation in drawing up the ultimatum, which was, so it is said, "an affair for Austria," and it did not receive the text until the 22nd, although it had twice demanded it. The secretary of state, von Jagow, in the absence of the chancellor examined it and found it too severe; the Austrian ambassador replied that it had already been despatched to Belgrade. The ultimatum which was presented on July 23, taxed Serbia with not having kept the engagement of 1909 to live on neighbourly terms with Austria and with having permitted the development of a subversive movement for the separation from Austria of certain parts of its territory. The ultimatum went on to enumerate the conditions demanded by the Austrian Government among which were clauses compelling the Serbian Government to dismiss all officers and civil servants whose names should be communicated to it by the Austrian Government and to admit to Serbia Austrian representatives who should collaborate with the Serbian Government in repressing the subversive movement. A reply was demanded within 48 hours without any discussion on the terms of the note. The Austrian Government treated the Serbs as a subject people.

The Triple Entente could only conclude that Austria was determined to make war, notwithstanding the opposition of Russia, and that she had taken this decision in agreement with Germany. Berlin believed that Russia was in no condition to go to war and thought that France and England would not intervene; but the German ambassador in London, Prince Lichnowsky, made known to Berlin that the British Government counted on Germany not to associate herself with demands that manifestly had for their object the provocation of war.

On July 24, in London, Paris and St. Petersburg, the German ambassadors delivered a note in which the German Government declared that the Austrian demands were "equitable and moderate" and would, if necessary, be enforced by military measures; the matter was one to be settled exclusively between Austria and Serbia. Germany desired "the localization of the conflict" (this note had been drawn up before the German Government had seen the text of the ultimatum). The French minister replied, merely expressing the hope that Austria would be able to enter into negotiations with Serbia. The British minister, Grey, declared that the Austrian ultimatum "surpassed anything which he had ever seen" and pointed to the danger of a European war "if public opinion in Russia should compel the Government to make war on Austria"; he proposed a mediation on the part of the "Four Powers not directly interested." The Russian minister, Sazonov, refused to accept the localization for, according to him, it was "a European question," but on the following day he declared that Russia was prepared to exhaust every endeavour to avert war. The German Government, however, believed that the Triple Entente would not go to the extent of making war, though the latter, they saw, were determined to maintain the independence of Serbia.

On the advice of Russia and France the Serbian Government replied to the ultimatum accepting the majority of the demands; as for the conditions which violated the rights of a sovereign

State it declared itself ready to submit them to the international tribunal at the Hague. The Austrian minister at once pronounced this reply unsatisfactory, and left Belgrade on July 25.

The German ambassador at Paris proposed to the French Government that it should use its influence with Russia to prevent the spread of the conflict, but he refused the French proposal of concerted action by the Powers both at Vienna and St. Petersburg. Germany wished to prevent Russia from acting and to leave Austria free. The British Government proposed a conference in London of the four Powers which should demand jointly the suspension of all active military operations by Austria, Russia and Serbia. The German Government refused, because it could not—so the chancellor wrote—"drag Austria before a European tribunal," nor could it set itself up as mediator between Austria and Serbia except "in a conflict between Austria and Russia." It persisted in wishing to localize the conflict, that is to say, to hand over Serbia to Austria, and it counted on the inaction of England. The brother of William II., Prince Henry, visited King George in London, and was asked by the king to do his best to keep out of the war. Sazonov proposed a direct negotiation to the Austrian ambassador and Berchtold replied that war had already commenced. This was not true, but Berchtold wished to create a definite situation in order to prevent a further move on the part of the Entente Powers.

On the evening of July 27, the German Government was informed by its ambassador in London that Grey had said to him that any military action on the part of Austria would be a "direct provocation" to Russia and that it was the duty of Germany to hold Austria in check. The British cabinet had ordered the fleet, which was about to disperse, to remain concentrated (July 28). The German chancellor informed Austria that Germany could not refuse all mediation, for it was important that they should appear to be forced into war. But he did not advise Austria to stop her military operations. The kaiser, who had returned to Germany, read the Serbian reply and wrote in the margin "a great moral victory for Vienna, but it dissipates every reason for war." He proposed only that Belgrade should be occupied as a pledge of the execution of their promises by the Serbs (July 28). Bethmann, who was informed by the German ambassador that Berchtold was proposing to dismember Serbia, demanded from him a declaration of his intention to reassure public opinion in Europe. But he advised his ambassador "to avoid creating the impression that we are desirous of resisting Austria."

Declaration of War Against Serbia.—On July 28, 1914 Austria declared war on Serbia by telegram and broke off the conversations in which she was engaged with Russia because they no longer served any purpose; on the 29th she began the bombardment of Belgrade. The Russian Government drew up two mobilization orders, the one a partial one with a view to war with Austria alone, the other a general one. Disagreement now became manifest within the Governments of both Russia and Germany as to the policy to be followed. For military reasons the general staffs desired to hasten their preparations for war in order to assure the advantage of offensive action, while the civilians for political reasons, sought to delay for fear of appearing responsible for breaking the peace. At first the German Government sought to intimidate Russia and its ambassador, Count Pourtalès, declared on the evening of the 28th to Sazonov, that a continuation of the Russian mobilization would compel Germany to mobilize; "it would be nearly impossible to prevent the European war." The Russian Government determined to order a general mobilization but the tsar, who was anxious for peace, cancelled the order and decreed instead the partial mobilization. In Germany on the same day, July 29, the general staff demanded an immediate decision in order not to leave the initiative to the enemy; Bethmann sought to delay the decision.

The Austrian Government finally declared to Russia on July 29 that it had no intention of annexing Serbian territories but that it could not accept the Russian proposal to respect "the sovereign rights of Serbia." Bethmann sought to avert a British intervention by proposing, on the evening of the 29th, to the British ambassador, Goschen, that if England would remain neutral Germany would not annex any French territory. Immediately there arrived a telegram from the German ambassador in London announcing Grey's declaration that if war broke out England could not remain a spectator. The German Government, advised moreover that Italy would not support her allies, during the night sent many communications to Vienna for the purpose of inducing Austria not to reject any project of mediation. The same evening the tsar proposed that the Austro-Serbian dispute should be submitted to arbitration and he despatched a personal telegram to William asking him "to exert very great pressure" on Austria. The kaiser replied that if Russia continued to mobilize he would be unable to influence Vienna: "It is on you that the weight of the decision lies."

The Russian and German Mobilization.—On the 30th the tsar gave way to his general staff, who pointed out that partial mobilization on the Austrian frontier would disorganize the general scheme of mobilization; he, therefore, gave the order for the general mobilization.

The Austrian council of ministers refused to suspend their operations against Serbia, and requested England to stop the Russian mobilization; as yet, it was unaware of the partial mobilization. On the advice of the German general staff, it ordered the general mobilization on the morning of the 31st. Both governments declared that the mobilization was a defensive one and would not preclude negotiations. On receiving information of the Russian mobilization, the kaiser proclaimed a state of war to be imminent and informed Sazonov that if the Russian order was not cancelled within 24 hours, Germany would consider herself at war with Russia. The Russian mobilization had, in Germany, given the impression that Russia was the aggressor; all parties, even the Socialists, united to pass the votes of credit and to defend Germany against the Russian invasion.

The Declarations of War.—On his return to Paris from St. Petersburg, Poincaré had telegraphed to Russia that "France would fulfil her obligations under the alliance," although continuing her efforts to preserve the peace. In order to avoid the risk of a military conflict, the French Government ordered its troops to withdraw to ten kilometres behind the frontier. On the evening of the 31st, von Schoen, the German ambassador, informed the French minister Viviani, that he would return on the following day to learn what would be the attitude of France in event of a war between Germany and Russia. The answer was made to him that "France would act as her own interests required." It has since been revealed that von Schoen was in possession of instructions that if France promised to remain neutral he was to demand the cession to Germany of Toul and Verdun as a guarantee. On August 1 a general mobilization was ordered in France almost simultaneously with Germany.

Realizing that war was inevitable, the French Government called upon England for assistance. But there the Liberal cabinet was divided, and the majority hesitated to launch Great Britain into a continental war in which its interests and its honour were not immediately engaged. Parliament was not in session and public opinion did not seem ready for war. The decision to take part in the war was precipitated by an action on the part of Germany. Great Britain, in common with France, Austria, Prussia and Russia was a signatory to the treaty of 1839 which guaranteed the neutrality of Belgium, and this obliged it to repel with armed force any violation of Belgian territory. In 1868 the Great Powers had similarly guaranteed the neutrality of Luxembourg. Grey had demanded on July 30 an assurance from the French and German Governments that the neutrality of Belgium would be respected. France gave this, but Germany declared herself unable to make any reply. The plan of the German general staff was to make a swift attack on the French army in order to crush France before the Russian armies were ready, and in order to avoid fighting on two fronts. The chief of the Austrian general staff, Conrad, had been informed that the German general staff calculated that the operations against France would be concluded 33 days after mobilization. But to act quickly the German army was compelled to pass through Belgium. On Aug. 2 it occupied Luxembourg.

The German Government declared war on France on Aug. 3,

alleging that the French had violated German territory. The German ambassador in Brussels handed to the Belgian Government a note demanding a free passage for German troops across Belgium, accompanied by a threat that if Belgium refused, she would be treated as an enemy, and adding that it was aware that French troops were about to enter Belgium. The German general staff, however, had actually drawn up this note several days previously and had prepared proclamations to the Belgian people. The Belgian Government refused; the German troops had already crossed the frontier. This intelligence decided the British cabinet to act; three ministers alone refused to support the war and handed in their resignations. The English ambassador, Goschen, delivered an ultimatum in Berlin, calling upon the German Government to respect the neutrality of Belgium; he was refused. The war began the night of August 4–5.

DIPLOMATIC RELATIONS DURING THE WAR

The Question of Responsibility.—The investigation of war responsibility does not lie within the sphere of this article. But after the Treaty of Versailles had declared Germany responsible for the war by calling upon her to pay for its ravages, the reproach of having started the war provoked in Germany an agitation over war guilt which has become one of the factors of European politics. It will be useful to examine the position of this question.

The secret documents published since 1919 do not confirm the opinion that was prevalent during the war that Germany had deliberately intrigued to inveigle France and Russia into a trap prepared for many years with a view to the extension of dominion by war. It is certain that no Government really desired a European war; Austria desired only a local war with Serbia; Germany supported her, as in 1909, in order to frustrate Russia. When the Russian Government had shown itself determined to defend Serbia, the German and Austrian Governments refused to retreat from the risk of a general war. This risk compelled the European States to make military preparations. It was Russia who took the initiative in ordering a general mobilization, and German public opinion has seen in this fact the proof of a determination to make war, and so has thrown the responsibility for the war on Russia. It was Austria and Germany, however, who first declared war; but neither a mobilization nor the declaration show who really willed the war. Undoubtedly international law was violated. It was violated when Austria sent an ultimatum to Serbia containing clauses incompatible with the rights of a sovereign State, and when she invaded Serbian territory in order "to chastise the Serbs," who were not her subjects. It was violated when Germany invaded Luxembourg and Belgium, notwithstanding the neutrality which she herself had guaranteed.

The Governments of the three empires wished to avert a general war but they were too distrustful of one another frankly to consult upon the means of avoiding it; for each feared to reveal its plan lest it should become the dupe of a bluff or ruse. France and England were powerless spectators of the conflict. France was bound by the Russian alliance; the British cabinet did not dare to risk action which had not been approved by the nation. The war was not the work of personal ambitions, but the result of the system of the three military empires, Austria, Russia and Germany. The civil authorities responsible for the acts of their Governments, did not venture to decide on war. Of the three emperors not one desired the war but all three, brought up in an entourage of officers and accustomed to show deference to military opinions, felt obliged to leave to the general staff, not only the decision as to how the war should be conducted but also the moment when it should be begun. The general staffs, eager to take action in order to deprive the enemy of the offensive, which was then considered the decisive factor, extorted from their sovereigns authority to take the initiative. The war was thus the result of a military plan. (*See* WAR GUILT.)

Course of the War.—The history of the war is treated elsewhere. (*See* WORLD WAR.) But inasmuch as military operations exercised a decisive influence upon diplomacy it may be as well to indicate here its general course. The general staffs of all the States were convinced of the great advantage to be derived from taking the offensive, and they each sought to take it in the hope of bringing the war to a speedy conclusion by a decisive victory. But the war lasted for more than four years without any offensive resulting in a lasting success.

The Austrian offensive in Serbia in 1914 was repulsed by the Serbs; the German offensive in France was stopped on the Marne; the Russian offensive in Prussia ended in disaster. The Serbian offensive in Austria and the Russian offensive in Galicia in 1915 were repulsed; the French offensives first in Artois then in Champagne, were arrested with great loss. The Italian offensive against Austria was checked on the Corso, and the British offensive against the Turks in the Dardanelles failed after a massacre of British colonial troops. In 1916 the German offensive at Verdun failed, the Russian offensive was checked on the borders of Galicia, and the Rumanian offensive resulted in the invasion of Rumania. In 1917 the British offensive was checked in Artois, the French in Champagne, the Russian at Tarnepol where the Russian army was destroyed; the Italian offensive was arrested by the *débâcle* of Caporetto (*q.v.*) and the Austro-German counter-offensive against Italy ended on the Piave. In 1918 the supreme offensives of the Germans in Picardy on the Marne and at Rheims were alike repulsed.

The war was decided not by victories but by the exhaustion of the armies and by the failing *morale* that manifested itself successively among the nations—in Austria in the defection of the Austrian Slavs, in Russia after the revolution, in Rumania, Bulgaria, and finally in Germany. In this war between two coalitions the one which possessed the greatest extent of territory, the greatest population, and the most abundant resources, ended by conquering the other, which at the outset had had the advantage of a better trained army, one able to operate on interior lines. But the coalition primarily achieved victory because as mistress of the seas she preserved the means of revictualling her armies and peoples, whereas the central empires had access only to two small ocean-highways—the Adriatic and the North Sea—which were blockaded by the navies of their enemies. Victory did not take the customary form of an invasion of the territory of the vanquished; the victor while yet in occupation of enemy territory had been converted into the vanquished by the exhaustion of his armies and by the demoralization of the civilian population.

The Neutrals.—The war opened between Austria and Germany on the one hand and Russia, France, Great Britain, Serbia and Belgium on the other hand. The Central Empires appealed to their allies. Italy replied that as Austria had taken the offensive, there existed no *casus foederis,* and that she could not give her support except on conditions deemed inacceptable by Austria. King Charles of Rumania was allied to the central empires by a secret treaty but a crown council decided that there was no *casus foederis,* and Rumania remained neutral. Turkey under the influence of the Germanophil Young Turks who were uneasy about Russia's projects against Constantinople, signed a treaty of alliance against Russia on Aug. 2 and on Aug. 6 Germany promised to lend her support in obtaining the abolition of the capitulations (*q.v.*). The Turkish Government permitted two German cruisers to enter Constantinople, but at the same time, in order to veil its intention, proclaimed the neutrality of Turkey. Ferdinand of Bulgaria had negotiated an alliance with Austria but, fearing that if he attacked Serbia, Serbia would be supported by Greece and Rumania, he remained neutral waiting to see which side was going to be victorious.

Turkey Enters the War.—The British and French ambassadors attempted to keep Turkey neutral by a promise to guarantee the integrity of her territory but the Russian Government would have preferred a war with Turkey which would have afforded her the opportunity to carry out her designs on Constantinople. The Turkish Government, foreseeing a victory for Germany, abolished the capitulations (Sept. 9), closed the Dardanelles, and finally despatched her fleet to bombard the Russian coasts. Russia declared war and the tsar in the manifesto of Nov. 2 announced the "solution of the historic Russian problem of the sea-board of the Black sea." The entry of Turkey into the war broke the line of communications between Russia and

her allies by the convenient route of the Black sea and threatened British supremacy in Egypt. England replied by annexing Cyprus and opposing the khedive of Egypt whom she replaced by his son, a protégé of Great Britain.

The Allied Coalition.—In consequence of her alliance with England, Japan entered the war on Aug. 23, and on Sept. 5, 1914, the three Entente Powers, Great Britain, France and Russia pledged themselves by the Pact of London not to conclude peace separately and not to lay down conditions of peace before they had been agreed in common. At the request of the Russian Government the Allies signed an agreement with Russia known as the Constantinople Agreement on March 18, 1915 which promised Russia, Constantinople and the Straits, together with a portion of the hinterland on either coast in Thrace and Asia Minor. Constantinople was to be a free port.

Italy had armed and opened negotiations with both parties. At first she did not demand from Austria more than the cession of the Italian-speaking Trentino, but as the war went on she determined to place a higher price on her support. In April 1915 she demanded from Vienna, as the price of her neutrality in addition to the Trentino, Gorz and Gradisca, numerous islands in the Adriatic, which should be handed over to the immediate possession of Italy, and a declaration of Austria's disinterestedness in Albania. On the advice of the Germans and of Conrad, the Austrian Government continued negotiations. But Italy preferred the offers of the Entente and undertook to support the allies "with all her resources" by the Treaty of London of April 26, 1915. She was promised by this treaty the whole of the Tirol south of the Alps, with its natural and geographical frontiers up to the Brenner; Istria as far as Guarnero and the islands, and the whole of Dalmatia, of which the southern portion was to be neutralized. In event of a partition of the Turkish empire, Italian interests were to be safeguarded in the Near East. On May 3 the Italian Government denounced its treaty with Austria and on May 23 declared war on her. Thereupon Germany broke off diplomatic relations, although Italy did not declare war on Germany until Aug. 1916.

Bulgaria.—The strategic position of Bulgaria and Rumania on a line of communication between Austria and Turkey rendered their support of peculiar value to the Central Empire. Russia brought pressure upon the Serbian Government to make concessions to Bulgaria in Macedonia; she promised Rumania the annexation of Austrian territory populated by Rumanian speaking inhabitants; but the fear of an attack by her neighbours prevented King Ferdinand, who had succeeded Charles in 1914, from committing himself even after the entry of Italy into the war. The Central Empires, requiring the aid of Bulgaria against Serbia, promised her all Macedonia. The Entente was powerless to make offers to Bulgaria without the consent of its Serbian ally, but the *skuptchilna* consented, on Aug. 16, 1915, to the cession of a portion of Macedonia, but subject to Serbia receiving territories to be conquered from Austria. Bulgaria, however, demanded immediate possession, and turning towards the Central Empires, she signed a treaty on Sept. 6, 1915, which promised her the annexation of nearly all Macedonia and that eastern portion of Serbia which she claimed as Bulgarian, and further, in event of an attack being made upon her by Rumania or Greece, she was promised the restitution of the territory she had lost in 1913. The Central Empires thus acquired a line of communication with Turkey, and embarked, in Oct. 1915, on a campaign that resulted in the occupation of Serbia.

Greece.—The Allies could only come to the rescue of Serbia by way of the Greek port of Salonika. The Greek cabinet was divided among itself and Venizelos, who had directed Greek policy since 1911, and who was supported by the majority of the chamber, worked in the interests of the entente. But King Constantine, who was a brother-in-law of William II., and a Germanophil, dismissed Venizelos in March 1915, and dissolved the chamber. After the elections Venizelos, who had returned with a majority, gave the Allies leave to disembark troops at Salonika. Constantine, however, refused to depart from his neutrality and the allied troops were disembarked in Oct. 1915, despite the protests of the Greek Government, and too late to save Serbia.

The Inter-Allied Council.—The Allies soon realized that diplomacy was an ineffectual way of co-ordinating military operations. The French minister for war, Millerand, visited London, and Asquith, the British prime minister, interviewed Joffre, chief of the French staff, at the British headquarters. As a result, the decision was taken to co-ordinate operations by conferences. The first conference was held at Calais in July 1915 by the British and French prime ministers, with the assistance of Lord Kitchener, Lord Crewe, Balfour, Millerand, Delcassé, Augagneur and Albert Thomas. In a single day it made strategical decisions that had been in abeyance for weeks. The second conference in Paris, on Nov. 17, between the chief ministers of the two States, resolved to reinforce the army at Salonika and discussed the question of landing at the Dardanelles. It further resolved to establish a committee for the purpose of co-ordinating allied actions and at a meeting between Briand and Asquith in London, in Jan. 1916, an organization was agreed upon. It was given the character of a consultative body, composed of the prime ministers in office with the collaboration of other ministers and technical experts. The object was to place the control of the military in civilian hands; for all the meetings were preceded by meetings between the general staffs. The first took place in Paris on March 26, 1916, and was attended by the prime ministers of France, Great Britain, Belgium, Italy and Serbia, and the ambassadors of Russia, Japan and Portugal. It passed decisions on proposals made by the general staffs, presented by Joffre, and established an Inter-Allied transport council in London.

A secret agreement concluded by Great Britain in 1915 for the creation of an Arab kingdom should be mentioned here, since it compelled Great Britain to come to an agreement with France for a division of their spheres of influence in Syria and Cilicia. This agreement, known as the Sykes-Picot agreement from the names of the negotiators, was communicated to Russia, but concealed from Italy, whose claims it controverted.

Rumania and Greece.—After the defeat of the Germans at Verdun and the success of the Russian offensive against the Austrians, the Rumanian Government, confident in the triumph of the Allies, signed a treaty of alliance and a military convention on Aug. 17, 1916, which promised to Rumania all Austrian territory inhabited by Rumanian-speaking peoples. Rumania at once entered the war, but its offensive was speedily repulsed and its territory invaded.

The Rumanian disaster gave an added importance to Greece as the sole country by which the Allies were able to invade eastern Europe. The quarrel between Constantine and Venizelos led to a civil war. The latter, supported by the Greek islanders, established a Provisional Government at Salonika under the protection of the Franco-British army and made war in Bulgaria. France and Great Britain were prevented by Russia and Italy from taking action against Constantine, who remained master of the old kingdom. An Inter-Allied conference at Boulogne on Oct. 20, 1916, composed of the Allied chief ministers, for foreign affairs, war, and the marine, commanders-in-chief, and the chiefs of the British and French general staffs, determined to give financial and military assistance to Venizelos. The conflict with Constantine was resolved by the intervention of the French Government, which demanded on Oct. 10, the disarmament of the Greek fleet and the control of the police and the railways. The excitement in Athens, which was encouraged by the king, resulted in a massacre of Allied marines and Venizelists. The crisis was not ended until 1917, when Constantine left Greece and Venizelos, returning to power, brought Greece into the coalition and into the war against Bulgaria.

United States.—In full accordance with their tradition of abstaining from all "entanglements" in European affairs, the United States at first held aloof from the war. President Wilson was led to intervention by the measures taken by the Allies against neutral ships for the purpose of preventing contraband trade with Germany. He announced to the British Government his desire to see the rights and duties of the United States respected in accordance with the principles of international law and

treaty obligations. He protested against the blockade of the North sea and demanded the liberty of the sea. Discussion was continued on the subject of the use of submarines, floating mines, and the seizure of merchant vessels.

The sinking of the "Lusitania" by a German submarine, involving the death of 124 Americans, aroused public opinion in the United States and Wilson informed Germany that he would be obliged to go to war if she continued to take the lives of American citizens. At the same time he promised to use all means at his disposal to raise the starvation blockade. The German ambassador, Count Bernstorff, declared that German submarines had already received orders not to attack passenger vessels. Notwithstanding this, the "Sussex" was torpedoed in March 1916, and American lives were lost. The United States despatched an ultimatum to the German Government, which promised not to sink merchant vessels without affording the passengers an opportunity of saving their lives; the Germans demanded in return an intervention on the part of the United States in London to force England "to recognize the laws of humanity." While he refused any intervention, Wilson exerted himself to the utmost to preserve peace. After his re-election he proffered his mediation to the belligerents on Dec. 18, 1916, inviting them to make known their conditions of peace, and expressing the hope of rendering peace durable by the creation of a League of Nations (*q.v.*).

First Peace Proposals.—After having occupied Russian Poland in 1915, Germany and Austria sought to obtain the military assistance of the Poles by giving them pledges for the future. The proclamation issued on Nov. 5, 1916, promised the restoration of an independent Poland which, however, would be closely united to the two empires. The Russian Government replied with the publication of a promise to establish a Great Poland under the guarantee of the Entente.

The Central Empires were now beginning to feel the privations of the blockade. The emperor Francis Joseph, who died on Nov. 21, 1916, was succeeded by the young and inexperienced Charles, who desired peace, and who communicated his desire to William II., by whom it was approved. The two emperors in a conference with their ministers and chiefs of staff, decided to suggest peace at a moment when their military successes would enable them to dictate conditions. In the name of Germany and her Allies, Bethmann-Hollweg addressed a note to the neutral States announcing "propositions" that should serve as a basis for a lasting peace (Dec. 12). Germany answered Wilson by proposing a direct negotiation between the belligerents in a neutral country.

The Allies denounced this offer as a manoeuvre calculated to promote discord between them. Lloyd George, who had become the head of a coalition ministry, declared that to enter into a conference with a Germany that claimed to be victorious without any notion of the propositions to be made would amount to "placing our heads in a noose." On Dec. 30 the Allies replied that the proposal was entirely unsubstantial, and they demanded expiation for crimes committed, and complete indemnity for all the destruction caused by the war.

On Jan. 10, 1917, they replied to Wilson with a statement of their peace conditions: Reduction of the territory of Germany; dismemberment of Austria by "the liberation of the Italians, Slavs, Rumanians, Czechs and Serbs from an alien rule"; and the expulsion of the Turks from Europe. Further, they announced that they adhered with all their heart to the idea of the League of Nations.

Judging the German reply to be too vague, Wilson invited the German Government to define more exactly its conditions of peace. Bernstorff was instructed to inform Wilson that Germany was unable to accept his offer of mediation because such an acceptance might give to her enemies the impression that the German offer of peace was inspired by fear. Wilson continued to work for a peace "by understanding" and he said, in January 1917, that "only a peace between equals can be durable." His confidant, Col. House, who in 1915 and 1916 had entered into conversations in Europe with the leaders of both groups of belligerents, besought Bernstorff to advise his Government to communicate to the President their terms of peace in order that he might then propose a peace conference. But a royal council in Germany, notwithstanding the opposition of the chancellor, had already determined to embark on unrestricted submarine warfare, which, according to the German admiralty, would force Great Britain to sue for peace in five months.

An Allied conference at Paris on Nov. 15 and 16, 1916, composed of British and French delegates, discussed the critical situation in Russia and later, in conjunction with Russian and Italian delegates, the Polish and Greek questions. The conference in London on Dec. 16 between the British and French statesmen drafted replies to Germany and America and discussed operations in Palestine and the extension of the British front in France. The Rome conference of Jan. 5, 1917, between the four European members of the alliance discussed the military and financial help to be given to Russia, decided the measures to be taken in Greece against Constantine, and the instructions to be given to Gen. Sarrail, commander of the allied army at Salonika.

America Enters the War.—On Jan. 31, 1917, Wilson was informed by Bernstorff that on Feb. 1 Germany would commence unrestricted submarine warfare. Accordingly, on Feb. 3, the President broke off diplomatic relations with Germany. It became known that Germany had offered Mexico her alliance in event of a war with the United States. On April 6, the United States declared war on Germany and in the following December on Austria. The majority of the Central and South American States also declared war, but without taking any military action; on July 22 Siam, and on Aug. 14 China, followed.

The Conference of St.-Jean-de-Maurienne.—The Italian Government, when it learnt of the secret Franco-British understanding about the Arab countries, demanded a precise interpretation of the article of the Treaty of London that dealt with the Italian claims in Asia Minor. Since Italy dominated the line of communication with Salonika, the British and French premiers entered into a discussion with the Italians on April 17, at St.-Jean-de-Maurienne, which resulted in a secret compact by which Smyrna was promised to Italy. France proposed to demand the abdication of Constantine, but Sonnino rejected the proposal.

The Austrian Peace Negotiations.—The emperor Charles and his foreign minister, Count Czernin, in vain endeavoured to dissuade Germany from undertaking submarine warfare. They perceived that the Austrian monarchy was threatened by the revolt of its Slav subjects, and, knowing that the Allies did not desire the destruction of the Habsburg monarchy, they worked to obtain a peace by understanding. When Bethmann-Hollweg visited Vienna in March, Czernin told him that Italy had made overtures of peace and that France seemed disposed to negotiate. Bethmann, while agreeing to everything in principle, objected that France would demand Alsace and that he would not dare to suggest it to the emperor or the German nation; he therefore advised negotiations on the basis of an exchange of territory. Czernin demanded that Germany should cede Alsace to France and receive Poland in compensation; Austria to be permitted to indemnify herself in Rumania. The military commanders who directed the policy of Germany were against this proposal, and wished, on the contrary, to deprive France of the Briey mines and to force Belgium into an economic and military union with Germany. An agreement, concluded at Kreuznach on May 17, between the Austrian and German Governments, guaranteed to Austria the integrity of her territory and certain acquisitions in the Balkans. Germany, in event of obtaining the annexation (*Angliederung*) of Courland and Lithuania and the protectorate (*Anlehnung*) of Poland, was prepared to agree that Rumania should come within the Austrian sphere of influence.

The German Government was ignorant of the secret negotiations with France in which the emperor Charles was already engaged through his brother-in-law, Prince Sixtus of Parme, who had arrived in Vienna following the departure of Bethmann-Hollweg. Czernin did not approve of the proposed conditions, and Charles, without advising Czernin, despatched by Sixtus, on May 24, an autograph letter addressed to the president of the republic, Poincaré, in which he professed himself willing to support in Berlin "the just claims of France to Alsace-Lorraine" and to work

for the re-establishment of Belgium and Serbia as sovereign States; he further agreed to grant Belgium an indemnity and to give Serbia an outlet to the Adriatic. The Allies regarded this letter as a proof of the weakness of Austria and observed that no mention was made of a cession of territory to Italy. At the conference of St.-Jean-de-Maurienne, Sonnino declared that he could admit no discussion of "the aspirations of Italy as recognized in the Treaty of London," and he added that Italy could never conclude a "white peace."

The Russian Revolution.—The March Revolution of 1917, by which the tsardom was overthrown in Russia, left Russia still a member of the alliance of 1914. The Provisional Government carried on the war with the support of all parties—even of the Socialists—with the sole exception of the Bolsheviks. But the regulations introduced by the revolutionaries into the army, and the revolutionary propaganda for the return of the troops to their homes, paralysed the Russian army. The Bolshevik leaders, some of whom had returned to Russia through Germany, established themselves in St. Petersburg and engaged in a violent propaganda against the provisional Government. Socialists throughout Europe gave their support to a proposal of the Germanophil Dutch Socialist, Troelstra, to hold a conference at Stockholm, in a neutral country, for the purpose of concerting measures to compel the belligerents to conclude peace, and to force them to make known their war aims. Kerensky, the Russian president, and Arthur Henderson, the leader of the British Labour Party and a member of the British cabinet, gave their support to the proposal, which was also favourably regarded by Lloyd George. At a conference in London on May 28, composed solely of British and French representatives, any participation in the conference at Stockholm was rejected and passports refused to British and French delegates. This conference further took measures to reorganize the Salonika front.

The collapse of the Russian army forced the Allies to take certain decisions. A great inter-Allied Conference was held in Paris on July 25, composed of representatives of Great Britain, France, Russia, Italy, Greece, Rumania and Serbia. At a further conference, on the succeeding day, were added representatives of Belgium, Japan, Montenegro and Portugal. These conferences decided to grant financial aid to the Government of Venizelos, discussed the proposal of establishing an allied base at Corfu and Italian operations in Epirus.

German Peace Negotiations.—The German nation, which was depressed by the privations of the blockade and the failure of the U-boat warfare, despaired of a victorious peace. On July 19 a majority in the *Reichstag,* which up to then had been the docile servant of the Government, passed a motion proposed by Erzberger, the leader of the Centre, in favour of a peace by understanding, without territorial acquisitions and financial or economic constraints. The resolution demanded freedom of the seas and announced the determination of the German people to fight on for so long as "the enemy Governments threatened Germany and her allies with conquest and oppression." Bethmann-Hollweg, attacked by the majority, resigned, and the new chancellor, Michaelis, deprived the motion of all real effect by his declaration that its objects were capable of attainment within the limits of the motion "as I understand it" a declaration that was regarded by the Allies as a sign of bad faith on the part of the German Government.

The peace negotiations that had been carried on secretly in Switzerland between unofficial agents—Baron Revertera, an Austrian diplomat, and Comte Armand, a French officer—in Aug. 1917, failed on account of the conditions to be imposed upon Germany. The deep resentment that had been aroused in the French and Belgian peoples by the ravages of war and the repressive measures of the Germans against non-combatants—measures that were exaggerated and distorted in propaganda—rendered a friendly understanding with Germany impossible of achievement.

The Pope's Intervention.—In agreement with the German Catholics and in an endeavour to save the Catholic Austrian monarchy, Benedict XV. appealed to the heads of the belligerent States to negotiate on the basis of arbitration, reparation and reciprocal restitution, and liberty of the seas. The Allies returned no reply, and Wilson sent a refusal. The British cabinet stated that it could enter into no negotiation that had not been preceded by an unequivocal declaration on the part of Germany that Belgium would be restored after the war. At a royal council at Potsdam on Sept. 14 it was decided, on Ludendorff's advice, that Germany should stand firm. The German reply to the pope, on Sept. 19, did not even mention Belgium, while a verbal note handed to the papal nuncio at Berlin, stated that Belgium must grant Germany the right to undertake commercial ventures and preserve the separation of Flanders as established by the Germans. Thus the peace-move of the Vatican ended in failure. Nor were the conversations in Belgium between Lancken and Coppée, and the Spanish negotiations attended by any greater success.

The Supreme War Council.—The Caporetto disaster led to the holding of a conference at Rapallo, on Nov. 7, between the French, British and Italian statesmen and the chiefs of staff, at which military measures were taken to avert the threatening danger. On the proposal of Lloyd George the conference determined to set up a central body to direct operations on all fronts. At a general inter-allied conference in Paris, on Nov. 29, a Supreme War Council was established which held its first meeting on Dec. 1. It was a permanent advisory body composed of the heads of the Allied Governments and its recommendations were not put into practice until they had been accepted by the Governments. Since it was composed of representatives of the British Colonies, India and the majority of the Allied Governments, its real authority became very great. Its deliberations have been kept secret. All that is known is that at its meeting at Versailles (Jan. 30–Feb. 2, 1918) it determined to constitute a general reserve for the whole of the armies on the Western, Italian and Balkan fronts, and entrusted the execution of this task to an executive body composed of military representatives of Great Britain, Italy, the United States and France. After the German offensive on March 21, a meeting of the council was held at Doullens, on March 26, at which Marshal Foch was charged with the duty of establishing co-ordination between the French and British armies; and, after the failure of the German offensive, the council, at its meeting at Abbeville on May 1, decided to abolish the military executive and entrusted to Foch the supreme command of the Allied armies.

Renewed Austrian Peace Moves.—In Germany, Count Hertling, the leader of the Catholic Bavarian Centre, became chancellor in Nov. 1917. He was inclined for peace but was powerless against the military leaders, Admiral Tirpitz, who had just founded, in September, the warlike *Vaterlands-partei,* and, above all, Gen. Ludendorff, who was the soul of the general staff. William II., yielding to their counsels, decided to continue the war. In France, Clemenceau, who had become president of the council, exclaimed in the chamber on Nov. 20, 1917 "La Guerre, rien que la guerre," and he adopted repressive measures against the pacifists. In England, Lord Lansdowne pointed out, in a letter to the *Daily Telegraph,* that a continuation of the war would entail the ruin of the entire civilized world and he suggested that the Allies should reconsider their war aims. In December the South African representative, Gen. Smuts, engaged in conversations with the late Austrian ambassador in London, Count Mensdorff-Pouilly, with a view to separate peace with Austria; they failed because Mensdorff's instructions compelled him to act in unison with Germany.

Charles and Czernin saw the Austrian monarchy threatened with a revolt of its Slav populations. In the *Reichsrat,* in May 1917, the Slav majority overthrew the ministry at the first meeting held since 1914. Charles thought that help might be obtained in England, but Lloyd George told the trade union delegates on Jan. 5, 1918, that England would support French democracy to the death in its demand for a "reconsideration of the great wrong of 1871," although she did not make war to bring about the breakup of the Habsburg monarchy. He outlined three indispensable conditions for peace: the re-establishment of the sanctity of treaties; a territorial rearrangement of Europe, based on the right of self-determination; and the establishment of an international organization to limit the burden of armaments and lessen the

probability of war.

Intervention of President Wilson.—The hopes of Charles were destroyed by the publication of Wilson's Fourteen Points (*q.v.*). The central European empires approved of the theoretical clauses, in which were advocated the abolition of secret diplomacy, freedom of the seas in time of war, commercial equality, reduction of armaments and a League of Nations. But their rulers refused to agree to the independence of Belgium, the cession of Alsace-Lorraine, the restoration of Poland and the freedom of the Straits. The Austrian Government, in particular, saw the ruin of the monarchy in the recognition of the right of its subject nationalities to autonomy and the surrender of its Italian-speaking lands to Italy. Wilson's programme imposed all the sacrifice on the Central Empires, while behind it lay the secret agreements between the Allies.

The German Government declared that, in view of the military situation, it was not in a position to negotiate on the bases laid down by Lloyd George, and demanded their revision, letting it be clearly understood that it would not cede any portion of Alsace-Lorraine. The Supreme Council at Versailles answered, on Feb. 4, that this declaration did not propound a suitable basis for negotiations.

Russia and Germany.—The second Russian Revolution of Nov. 1917 brought into power the Bolsheviks, who were eager for peace and enemies of the Ententes. The new Government invited all the belligerent States to conclude an armistice and to enter into negotiations for a general peace. The Allies refused the invitation, which was contrary to the provisions of the Treaty of London, and on Dec. 7, the Russians agreed to a suspension of hostilities with Germany and her allies, and subsequently, on Dec. 15, concluded an armistice to which Rumania was forced to be a party. The peace negotiations were made publicly at Brest-Litovsk (*q.v.*). The Bolsheviks at first embarrassed the delegates of the quadruple alliance by demanding for all nations that right of self-determination which spelt the ruin of the Turkish and Austrian empires; on Dec. 25 the delegates accepted the Russian proposals for a peace without annexation and indemnities, with a reservation that it must also be accepted by the Allies, who were invited to take part in the deliberations on this basis. As they refused, the negotiations were resumed on Jan. 9, 1918, for the conclusion of a separate peace. The leader of the Russian delegation, Trotsky, demanded the evacuation of German troops from the Russian provinces they were occupying, in order to allow full liberty for plebiscites; and he protracted the negotiations to facilitate revolutionary propaganda in the Central Empires.

A delegation from the Ukraine arrived at Brest-Litovsk to demand that Russia should be constituted a federal republic. On receiving a refusal from the Bolsheviks they proclaimed the independence of the "republic of the Ukrainian people" and concluded a separate peace on Feb. 9, in which Austria promised, in a secret clause, to erect into a separate crownland, Ruthenian Galicia. The Ukrainians promised to furnish a million tons of corn. But the Bolsheviks overthrew the Ukrainian Government, and the Ukraine was then occupied by Austro-German troops, who succeeded, with difficulty, in collecting a portion of the promised delivery of grain. Concessions made to the Ukrainians irritated the Poles, and they turned against Austria; a part of the Polish troops in Galicia marched into Russia, whence they were conveyed, under Gen. Haller, to France and there united to the Polish Legion.

In opposition to the German officers by whom the negotiations were conducted, Trotsky announced on Feb. 18 that Russia abandoned the idea of a formal treaty but regarded the war as terminated. Germany at once resumed the war, and forced the defeated Russians to sign the Treaty of Brest-Litovsk on March 3. Russia gave up Courland, Lithuania and Poland to the Central Empires, and pledged herself to accord liberty to Finland, Estonia, Livonia, Ukraine, and to certain Caucasian districts claimed by the Turks. The contradiction between German demands and German peace proposals was exploited by the Allied propaganda.

While concentrating her offensive power on the western front, Germany had left troops in Russia, where the Bolsheviks were threatened by the "White armies," led by generals of the former imperial army. Disquieted by the revolutionary propaganda, the German Government refused to send troops to aid the Red armies. But it signed an additional article to the Brest-Litovsk treaty (Aug. 27), in which it promised not to aid the creation of any new independent State within Russian territory, and received in exchange the right to include Lithuania and Estonia within its sphere of influence.

With almost its entire territory occupied by enemy troops Rumania was forced by an ultimatum to accept the preliminary conditions of the peace of Bufta (March 5), but the victors could not agree upon the distribution of the booty. Peace was not finally concluded until May 7, in Bucharest, by the Germanophil ministry of Marghiloman; Rumania agreed to cede all the Dobrudja (*q.v.*) and place herself in economic dependence upon Germany. This treaty was not ratified.

The Fall of the Austrian Empire.—Germany's allies were annoyed by her separate agreement with the Bolsheviks. The Austrian Government complained that Germany had rendered peace impossible by refusing to make sacrifices in the West. An organization that had been set up in London under the control of Lord Northcliffe in Feb. 1918, for propaganda, announced to the enemy countries that it was "impossible to renounce the liberation of the oppressed peoples of the Habsburg monarchy." The leaders of the Southern Slavs, who were refugees abroad, had united, together with the representatives of the kingdom of Serbia by the Pact of Corfu, July 20, 1917. The Italians who had been rendered more conciliatory by peril, agreed to hold a congress in Rome, in April 1918, for the refugees from all the Slav and Rumanian lands of the Austrian empire. The dispute between the Italians and the Southern Slavs over Dalmatia—a Slav country that had been promised to Italy by the Allies in 1915—was settled by a friendly agreement. A mixed commission of British, French and Italian representatives, directed from the Italian headquarters a propaganda among the Slav troops of the Austrian army.

The danger became more pressing. Czernin, in an endeavour to make known the obstacles to peace, blamed Clemenceau's refusal to renounce the French claim to Alsace-Lorraine. Clemenceau, in reply, stated that the offer of its restoration came from Austria and published the emperor's letter of March 1917. Czernin withdrew. This revelation, that the emperor had sought to betray his allies by concluding a separate peace at their expense, aroused in Germany violent resentment against Charles, who felt obliged to visit the German headquarters at Spa with his new minister, Burian. There they agreed to the establishment of political, military and economic union between the two empires both during and after the war. This agreement was interpreted by the Allies as a movement towards the German domination of the whole of Central Europe. The apprehension that this step inspired won adherents for the idea of a partition of the Austrian empire, which had hitherto been vigorously opposed by the diplomatic world. The French Government recognized the national Czechoslovak council in Paris, presided over by Prof. Masaryk, as the supreme organ of an independent nation (June 1918); and the British Government (Aug. 9) and the United States (Sept. 3) followed its example. The status of an Allied army was accorded to the Czechoslovak legions fighting in Siberia or raised in Italy and France, and the national council at Paris admitted the rights of an Allied Government.

After the failure of the German offensive in France, a conference of German statesmen and generals was held at the general headquarters at Spa, on Aug. 14. Ludendorff admitted that all chance of a victory had disappeared, but added that he hoped to fight a defensive action which might incline the enemy towards peace. Charles and Burian, who had come to Spa, declared that Austria could not face another winter campaign. The Bulgarians and Turks also announced their inability to continue the war, and Hintze, the secretary of State for foreign affairs, sought and obtained authority to open negotiations for peace. But the German Government still hoped for a military success, and wished to negotiate through the intermediary of a neutral State, while

Burian demanded an immediate appeal to all the belligerents. In September, Hintze visited Vienna to negotiate an agreement. When the German army was forced to retreat, Burian determined to act without Germany; and he appealed to all the belligerents to negotiate for peace. But Wilson replied that the American Government was neither able nor willing to agree to a conference on a subject on which he had already clearly defined their attitude.

The Surrender of the Quadruple Alliance.—Bulgaria was the first to sue for peace. After the collapse of her army, the Government under Malinov, a sympathizer with the entente, not having received a reply from the Central Empires, proposed an armistice, which was granted on Sept. 29. Ferdinand abdicated. In Turkey, after the British victories in Palestine, Enver and Talaat, who had supported Germany, fell from power. The British admiral concluded an armistice on Oct. 31 which placed Constantinople and the Straits in the hands of the Entente and obliged the Turks to break off relations with the Central Empires.

Unable to resist the Allied offensive, which had been strengthened by the participation of American troops, Ludendorff at the end of September begged to be allowed to apply for an armistice and in spite of the opposition of the new chancellor, Prince Max of Baden, who would have preferred direct negotiations for peace, was granted permission, with the result that on Oct. 4, the German, Austrian and Turkish Governments appealed to Wilson for an armistice. On Oct. 8 Wilson answered that he could not consult his allies until the Central Empires had admitted their defeat by evacuating all Allied territory. He asked whether the chancellor spoke in the name of "the constituted authorities of the empire who have so far conducted the war." On Oct. 14, he demanded the cessation of submarine warfare and that the evacuation should be carried out so as to provide absolutely satisfactory safeguards and guarantees of the maintenance of the present military supremacy of the Allied armies. On the 16th, the emperor Charles, in order to appease Wilson, published a manifesto in which he announced the transformation of the monarchy into a Federal State; but he preserved the unity of the Hungarian kingdom, that is to say, the domination of the Magyars over the Slavs. On the 18th, Wilson replied that the United States having already recognized Czechoslovakia as a belligerent State, and the "justice of the national aspirations of the Southern Slavs," it was for these people to decide for themselves what they would accept. Before according an armistice, Wilson, on the 23rd, made it clear that none would be granted unless thereby a renewal of hostilities on the part of Germany was rendered impossible, and he declared that "the nations of the world do not, and cannot trust the word of those who have hitherto been the masters of German policy." If he had to continue to negotiate with the military rulers and monarchist autocrats of Germany he must insist, not on negotiations, but on surrender. Thereupon Ludendorff demanded a levy *en masse* for the defence of the Fatherland, and when the other generals declared further fighting useless, Ludendorff resigned (Oct. 26).

The Austro-Hungarian army in Italy, disorganized and routed, requested an armistice and on Nov. 3 signed a capitulation which compelled them to surrender unconditionally and deprived them of any right to appeal to Wilson's Fourteen Points. The Inter-Allied Conference in Paris, from Oct. 31 to Nov. 4, discussed the conditions of the armistice to be granted to Germany on the basis of the Fourteen Points and came to an agreement, with the exception of a reserve as to the freedom of the seas. The note which was sent to Germany on Nov. 5, in the name of President Wilson, announced that the Allies were ready to conclude peace on the conditions and in accordance with the principles laid down by Wilson. Germany was to pay compensation for all damage inflicted on the civilian population and their property. Marshal Foch communicated these conditions to the German delegation. The Germans found them much more severe than they had anticipated, but the general staff declared that resistance was impossible. Germany was in revolution and the chancellor, acting under the pressure of the Socialists, announced the abdication of the kaiser and the crown prince, and on Nov. 9 a republic was proclaimed. The Provisional Government set up by the Socialists announced its willingness to accept the armistice, which was signed on Nov. 11, in the Forest of Compiègne, by a delegation headed by Erzberger, the leader of the Centre Party, and with the approbation of Marshal Hindenburg.

EUROPE AFTER THE WAR

An account of the events which have disturbed the peace of Europe since the World War will be found in the special articles (*see* VERSAILLES, TREATY OF; PARIS, CONFERENCE OF; LEAGUE OF NATIONS; REPARATIONS AND DAWES PLAN; LOCARNO; *see* also DANZIG; VILNA; MEMEL; FIUME; CORFU; SAAR; RUHR; and RHINELAND). It is only necessary here to emphasize the characteristics of the new Europe that emerged from the war and to indicate the general course of relations between the different European States. Not only was the World War the greatest known to history by reason of its extent, the size of the armies engaged, the number of casualties and the greatness of the devastation and cost; it resulted in a political, social and territorial revolution which exceeded in violence and results all previous revolutions. Europe emerged transformed.

The Transformation of Europe.—Nearly all the European States had been involved sooner or later in the war; only Spain, Switzerland, Holland, Denmark, Norway and Sweden had remained neutral. The Napoleonic wars resulted in a general re-distribution of Europe; so, too, the World War resulted in yet another distribution—but in a very unequal manner. The national States formed on the exterior parts of Europe preserved their territories—some intact (Sweden, Norway, Luxembourg, Holland, Switzerland, Great Britain, Portugal and Spain); others, with one exception, increased their territory in accordance with the principle of nationality. Thus France recovered Alsace and that part of Lorraine which she had lost in 1871, Belgium received back the cantons which had been taken from her in 1815, and Denmark obtained the Danish portion of Schleswig. Serbia and Rumania received large accessions of territory through annexation of districts inhabited by Serbian and Slovene or Rumanian-speaking peoples, while Italy not only received Italian-speaking districts of the Trentino, Trieste and Zara, but all the southern portion of the German-speaking Tirol and the Slovenian districts on the Adriatic.

The three military empires, which covered the great central mass of Europe, were reduced or dismembered by the separation of all the districts inhabited by peoples of a foreign nationality. The German empire lost, apart from the districts restored to France, Belgium and Denmark, all its eastern Polish-speaking districts, Posen, West Prussia, the district of the Kashubes, and that part of Upper Silesia which voted in the plebiscite taken in 1921 for annexation to Poland. For economic reasons, Danzig and the Saar mines were the subject of special treatment.

The Russian empire lost all the territories on its western frontier peopled by foreign nationalities:—Finland, which was already autonomous, Estonia, Latvia, Lithuania and Russian Poland were erected into sovereign States. Some parts of White Russia and of Ukrainian Volhynia were annexed to Poland, while Bessarabia went to Rumania.

The Austro-Hungarian empire disappeared, and the two former dominating peoples kept only that territory in which their nationals formed the majority of the population. They formed two little national States—German-Austria and Hungary; of the rest of the empire part was divided among three neighbouring States, Italy, Serbia and Rumania, and the rest helped to build the revived Poland and the new State of Czechoslovakia.

The dismemberment of the Austro-Hungarian empire altered the dimensions of the two Balkan States, whose territory has been extended far beyond the Balkan peninsula; Rumania united within her frontier all Rumanian-speaking peoples; Serbia has become the kingdom of the Serbs, Croats and Slovenes, or Yugoslavia. The rest of the Balkan peninsula was divided between Greece, a diminished Bulgaria and Albania.

This rearrangement of the map of Europe increased the number of sovereign States and upset the balance of power. In 1914,

excluding the Ottoman empire, there were six great Powers. There are now only five; as against one State of moderate size (Spain), there are now five—Spain, Poland, Rumania, Czechoslovakia and Yugoslavia; as against 11 small States there are now 16, including five new States, Finland, Estonia, Latvia, Lithuania, Albania and two created out of the débris of the empire, German-Austria and Hungary; as against two very small States there now remains but one, Luxembourg. Thus the total has been raised from 20 to 27. Europe has never before had so many States of medium size. It has been impossible to exclude them from the European concert, in which they have filled the gap between the Great Powers and the little States.

The Political Revolution.—Only in one part of Europe did the war bring about a political revolution. All the national States other than the Central Powers retained their representative and democratic Constitutions; only three were republics (France Switzerland and Portugal); all the rest were, and have remained, at least officially, constitutional monarchies. The three imperial dynasties, the Habsburgs, Romanoffs and Hohenzollerns have disappeared and their States have, for the most part, been turned into republics on the French model of a democratic parliamentary republic with an elective president, and have extended universal suffrage to women. Hungary alone has sought to retain the monarchy, although she is still without a king.

Russia was organized by the Communist party into a federation of republics, the Union of Soviet Socialist Republics (U.S.S.R.). The proletariat, which is the legal sovereign, is represented by a congress elected on a franchise restricted to proletarians of both sexes. The Communist party wields the dictatorship in the name of the proletariat under the form of an absolute and centralized round. This form of government did not originate in Russia, but in the principles of Marxism, and may be regarded as being not only the national organization of a State, but also an instrument by which to consummate the proletarian revolution throughout the world.

These revolutions have upset the ratio between the types of political régimes. Before the war Europe contained only three republics as compared with 17 monarchical States, and including five great Powers, one medium Power, nine minor States and two very small States. Since Greece has become a republic there remain only 13 monarchies, including the two great Powers, Great Britain and Italy, Hungary, a monarchy without a king and Albania a kingdom since 1928. There are now 13 republics, including three Great Powers, France, Germany and Russia. Thus the greater part of Europe has become republican.

The Financial Revolution.—The war involved the belligerent States in unheard of expenses, of which only a very small part was covered by taxation. The Governments were forced to have recourse to loans of different kinds, and with the exception of Great Britain, the issue of paper money in such quantities that the real value of the legal currency became depreciated in an unprecedented manner. The national expenses were increased by the interest on these loans to a degree which made it impossible to balance the budgets, and upset the value of money, which is the standard for all values. This policy was pursued by nearly all the States, even after the peace and resulted in a chronic deficiency in budgets, the fall of State stock, the depreciation of currency and in three States, Russia, Germany and Poland, ended in complete bankruptcy. England alone has been able to restore her currency to par. Economic life became completely revolutionized by high salaries and high cost of living, sudden fluctuations of exchange, and—in England—by unemployment on a scale never before reached.

The financial and economic crisis became the dominant interest of politicians throughout Europe, and it has been the task of Governments to find expedients to enable them to meet their loan liabilities and balance their budgets. This preoccupation so strengthened the national sentiments that all the Continental States were moved to raise their customs duties to an unprecedented height. It also brought about an augmentation in the wages and pensions of the labouring and commercial classes, weakened the resources of the privileged classes, equalized the standard of life, raised the condition of women, and in brief, Americanized Europe.

The Destruction of the Concert of Europe.—The change in international relations was reflected in the negotiations that resulted in the Treaty of Versailles. Of the six great Powers forming the European concert, three were absent; Austria was destroyed; Bolshevik Russia had become isolated; Germany was the object of the negotiations without being called upon to take part in them. The treaty that has been nicknamed by the Germans "the dictation of Versailles," disarmed Germany, compelled her to submit to a military occupation and deprived her of any active part in European politics. The settlement of Europe was thus regulated by three European Powers, Great Britain, France and Italy, together with Japan and the United States. Wilson had announced that the procedure would follow another method than that employed by the Congress of Vienna in which decisions had been arrived at in secret by "potentates" without any regard for the feelings of the people. He endeavoured to work in public and to put into action the principle of the right of peoples to determine their own fate. But in reality the deliberations were secret, the work was done by commissions whose personnel had been chosen by the Governments, and the final decision was made by a council composed of the Governmental chiefs of the five great Powers. Having little interest in European affairs, Japan left these matters to the four other Powers, who became known as the Big Four, and since the Italians were reduced to play a secondary rôle, the decisions were taken by three great Powers, Great Britain, the United States and France, which meant in effect, by Lloyd George, Wilson and Clemenceau. When the Allies had reached an agreement on the conditions of peace, their agreement assumed the force of a contract which could not be discussed without dissolving their unity, and they imposed it upon the vanquished in five distinct treaties. When Wilson refused to agree to the reserves which the American Senate added to the treaties, the United States withdrew from the concert and the three European Powers, Great Britain, France and Italy, alone remained. This rump of the concert of Europe undertook the application of the treaties and the chiefs of the Governments continued to compose a Supreme Council (*q.v.*) which settled the affairs of Europe in conferences between ministers that were held at Spa, in July 1920, in London in Feb. 1921, and at Genoa in April 1922.

Matters of secondary importance were left to the Conference of Ambassadors (*q.v.*), created in 1920, and meeting in Paris, whose functions were limited to the execution and interpretation of treaties, received the reports of the commissions charged with the delimitation of frontiers, and settled the territorial arrangements resulting from the plebiscites ordained by the treaties. Its members were each responsible to their own Governments and it operated as a clearing house for avoiding the delays incurred in ordinary diplomatic procedure.

The New Organ of International Law.—By accepting the Covenant, which created the League of Nations, the signatories of the Treaty of Versailles introduced into international relations a principle and a new system. From the earliest times the conduct of Governments had been regulated solely by an indefinite tradition, which, even when embellished by the name of international law, consisted solely in variable customs without any obligatory force. Interests of State as interpreted by the sovereign, were the sole rule of policy, and the Governments conducted their relations with other States according to the principles of Macchiavelli, which were revived from Bismarck's time under the name of *Realpolitik*. The European congresses amounted to no more than temporary organizations set up to settle transient matters and were composed solely of representatives of the States whose interests were directly involved.

The war inspired in the European peoples a passionate desire to prevent its recurrence by imposing on their Governments as a duty the maintenance of peace. The League of Nations is an institution radically different from a congress of the European concert. It is a permanent body with a staff of permanent employees holding periodical meetings and always prepared to act

without delay in regulating differences between States before they have had time to develop into dangerous conflicts. Its power is not limited to any region or to any question, and extends over the whole sphere of relations between all the States-members. Neither does it work after the fashion of the congresses, in the tense atmosphere of the capital of a great Power, but at Geneva in the calm surroundings of a neutral town. It is its express mission not to serve particular interests, but to maintain peace by demanding from all States respect for treaties and international law. For the first time the Governments have recognized a moral obligation to submit their activities to the rule of universal justice.

From the former concert of Europe the great Powers have preserved for themselves the privilege to a permanent seat in the executive Council, but they are in a minority as compared with the representatives of States elected by the Assembly, while in the Assembly itself all States are on an equal footing. The discussions of the Assembly and the Council are held in public, and although secret intrigues outside the meetings may not be without influence, the publicity, and the meeting together in Geneva, of statesmen from the whole world has given to the small nations an influence which they could never have attained in the days of the concert of Europe. They use this influence for the maintenance of peace by the creation of an international public opinion which makes itself felt in the Governments of the great Powers. The settlement of difficulties is facilitated by means of the Court of International Justice set up at The Hague in 1920–21.

The League was endowed by the treaties with permanent powers in regard to the colonial mandates, National Minorities, Danzig, the Saar Basin, in virtue of which it has already taken numerous decisions. The great Powers have in addition, by common agreement, entrusted it with the settlement of the Upper Silesian question, which proved beyond the capacity of the Conference of Ambassadors. Its decision, which was put into operation without delay, established a precedent for an extension of its authority. It also regulated with success the differences between Sweden and Finland over the Åland Islands in 1921, the frontier differences between Albania and Yugoslavia, and frontier incidents arising between Bulgaria and Greece.

Conflict with Communist Russia.—War was prolonged in Russia by the campaign carried on by the White generals, supported by the Allies, against the Red armies, while the Moscow Government sought to promote Communist revolutions in the European States. This crisis was of short duration and only a single country, Hungary, was governed for a few weeks by Communists. After they had driven the Polish troops from the Ukraine, the Red armies arrived within sight of Warsaw before they were thrown back in disorder in 1920. The Soviet Government concluded peace treaties at Riga with the Baltic States.

The Communists repudiated the Russian debts, annulled concessions to foreigners, and confiscated their deposits in the banks. At first the European Governments refused to recognize the Soviet. But industrial and commercial interests wished to resume relations with Russia in order to open up her stores of petrol, wheat and minerals. The Bolsheviks appealed for foreign capital to reorganize their industry. The ***rapprochement*** began with the Treaty of Rapallo, which they signed with Germany in 1922, during the Genoa Conference. The Soviet Government was subsequently accorded official recognition by the ministries of Ramsay Macdonald in Great Britain and Herriot in France in 1924; and the other States followed suit. Subsequently Russia kept a diplomatic representative in all the capitals, and made use of them to stir up revolution. The Conservative cabinet in England adopted measures, in 1927, to counteract this propaganda and in May of that year raided the offices of the Soviet Commercial Delegation and broke off diplomatic relations. The Soviet maintained a hostile attitude towards the League of Nations and refused in 1926 to ask to be admitted to membership.

The Successor States and the Little Entente.—The destruction of the Habsburg monarchy, which was an event without precedent in the history of modern Europe, was the work, not of its enemies but of its subjects. The national States, new or transformed, which took the place of the empire, had to reorganize a whole system of institutions, and to build up a political and administrative personnel in countries devastated by four years of war and plunged without preparation into a system radically democratic. The treaties compelled them to grant complete equality of political rights to national minorities of different language and religion; the right of teaching their language in schools and using it in the Church services and law courts was placed under international guarantee and control of the League of Nations (*see* MINORITIES).

The dismemberment of the Austrian empire substituted several States, each with its own independent Government, for one vast united territory; it resulted in internecine conflicts such as were usual in the Balkans; hence the catchword "the balkanization of Europe." But the Governments of the Successor States (*q.v.*) felt themselves to be threatened by the same adversaries, and therefore banded themselves together into what is known as the Little Entente (*q.v.*) without consulting the great Powers. Beneš, the foreign secretary of Czechoslovakia, took the initiative; he concluded a treaty of defensive alliance with Yugoslavia in Aug. 1920, and a similar treaty with Rumania, April 1921, who thereupon concluded a treaty with Yugoslavia, June 1921. The three States, to all of which a part of Hungary had been annexed, thus protected themselves against the protests of the Hungarians. They intervened, Oct. 1921, in order to prevent the restoration of Charles as king.

Rumania, in order to defend herself against Russia, concluded a treaty with Poland, 1921; Czechoslovakia concluded a treaty of guarantee with Austria, Dec. 1921, the first of the kind between one of the victorious and one of the vanquished States. The system of guarantee was completed, 1924, by the Treaty of Rome concluding an alliance between Italy and Yugoslavia and the treaty of alliance between Czechoslovakia, Italy and France. All these treaties were registered by the League of Nations.

The destruction of the economic unity of the Austro-Hungarian empire raised a further problem. Vienna had been the financial centre of the banks, distributing capital and directing commerce in all the territories. Now each of the Successor States regulated as sovereign its financial policy, each wished to create its own industries and to protect them by high tariffs. Commercial ties between the countries were rudely broken; communications were upset by the division of the lines and rolling stock of the railways. Two remedies were suggested; a customs union between the Successor States, and the union of Austria and Germany; they were refused both by the States and by the Great Powers.

Conflicts on the Adriatic.—Italy had not obtained exclusive domination of the Adriatic. The treaty had given Dalmatia to Yugoslavia and made Fiume autonomous. A sudden attack put Italy in possession of Fiume. The Fascist Government of Mussolini after 1922 gave an aggressive air to the policy of Italy by demonstrations devised to appease national *amour propre*, but this was balanced by a prudent diplomatic practice. After the murder of Italian officers belonging to the commission for the delimitation of the Greco-Albanian frontier, he sent a fleet to occupy Corfu; but he accepted the verdict of the Conference of Ambassadors. He concluded with Yugoslavia the treaty regulating the question of Fiume, 1924, by a division of territory. He showed considerable diplomatic activity in eastern Europe by concluding treaties with Hungary, Greece and Rumania, which were interpreted as an attempt to isolate Yugoslavia. He worked for the imposition of Italian influence in Albania by the Treaty of Tirana (1926). The Serbs protested; the quarrel seemed to be made up after negotiations between Italy, France and Yugoslavia, which resulted (1927), in a treaty between France and Yugoslavia.

Polish Disputes.—The treaties had given Poland a large tract of territory without fixing its definite boundaries, which did not become settled until after a series of violent quarrels with her neighbours. The Poles made war on the Ukrainians (1919) in order to subject Lemberg and Galicia, and imposed on these Ruthenian-speaking countries—instead of the autonomy intended by the treaties—a system of occupation which was tolerated by

Europe. The invasion of the Ukraine, pushed as far as Kiev, was stopped by the Russian Red army (1920). On the side of Lithuania, after the sudden attack on Vilna (*q.v.*) (1920), the frontier was drawn by the Conference of Ambassadors, who accepted the *fait accompli*; but Lithuania refused to recognize it. The attempt to form an alliance of the Baltic States against Russian communism made at the Conference of Warsaw (1921), failed on account of a disagreement with Finland. The Russian frontier, fixed by the Treaty of Riga, left Poland in possession of the occupied territory. On the side of Germany the settlement of the frontier necessitated the intervention of the League of Nations over the question of Upper Silesia, where the plebiscite resulted in an open war between the Poles and the Germans.

Relations with Germany.—The chief preoccupation of European diplomacy has been the relations between the Allies and Germany, on which depended the agreement between Great Britain and France. The French formula, "restitution, reparation, guarantee," required a complicated system. The French general staff claimed as a guarantee the indefinite military occupation of the left bank of the Rhine; Clemenceau accepted an occupation limited to 15 years in exchange for an American and British guarantee. But the refusal of the United States to ratify the treaty, annulled this promise; the French Government have therefore been occupied ever since in finding an effective guarantee. French nationalists, who have become influential since the success of the *Bloc National* in the elections of 1919, hoped to make themselves secure by reducing Germany to a state of partition; they hoped to detach from Berlin the Catholic Rhineland. The British Government saw no lasting security except in a reconciliation with Germany, and fought against all schemes for destroying German unity.

The Allied Governments did not desire to fix the sum due from Germany for reparations, for fear of creating too much disappointment in France. They called three conferences, at Spa (1920), London (1921), Genoa (1922), for the purpose of settling with Germany the best means of obtaining her payments and the share each ally was to receive. The French Government tried to work upon Germany by exerting military pressure; they took the opportunity of the dispatch of German troops against the communists in the neutralized zone to extend their military occupation as far as Frankfurt (1920), and then into the Ruhr. The president of the republic, Millerand, intervened to put a stop to the negotiations at Genoa. The accord between Great Britain and France was therefore broken; and Lloyd George, after his resignation, conducted an open campaign against French policy. The Bonar Law ministry tried to re-establish friendly relations at the conference of Paris, Jan. 1923, by a plan which diminished the French debt to England. The Poincaré ministry rejected it and carried out a previously thought-out plan to work German industries under the direction of French engineers, and occupied the industrial region of the Ruhr (*q.v.*). The passive resistance of the Germans ruined German currency and stopped the payment of reparations. At the same time armed bands made "separatist" demonstrations on the left bank of the Rhine with the connivance of the French army of occupation.

The crisis was resolved in 1924 by the adoption of the Dawes Plan (*q.v.*). The victory of the party of the Left at the elections, who represented the peace-loving mass of the French electorate, led to the formation of a ministry which pursued a more pacific policy in foreign affairs and re-established good relations with Great Britain.

The Guarantee Treaties.—The French Radical ministry and the British Labour Government agreed to revive through the League of Nations the scheme for general disarmament promised by the Treaty of Versailles. The French Government saw in this a means to obtain the abortive guarantee of 1919 by making it a preliminary condition of disarmament. Its formula was "security, disarmament, arbitration." The Geneva protocol of 1924 was drawn up in this spirit; the members of the League of Nations were to undertake to support each other against all aggression and to enforce sanctions against the aggressor. But the British Government, representing the whole of the British empire, had to reckon with the repugnance of English opinion to any general commitment, and still more the refusal of the dominions, members of the League, to promise to intervene in purely European conflicts. The protocol therefore was wrecked.

The scheme extended to all the members of the League seemed to be too great; Briand said "In order to ensure peace it is Europe which must be organized." The policy of guarantee was raised again in the form of special treaties, to which the British Government took no exception. The project proposed confidentially by the German to the British Government, March 1925, was accepted by France and discussed at Locarno (*q.v.*) in October. The agreement was signed in London in the form of treaties between Germany, on the one hand, and Great Britain, France and Belgium on the other. The contracting parties engaged themselves to abstain from all aggression, to respect the frontiers established in 1919 and to submit all differences between them to arbitration. Great Britain and Italy engaged themselves to guarantee the treaties by going to the help of any State attacked. This agreement meant that Germany renounced Alsace-Lorraine, but by accepting an arrangement which had in the first instance been imposed upon her by force, she treated with the other Powers on an equal footing. She was to ask for admission into the League of Nations and to receive a permanent seat on the Council.

France wished for an analogous agreement for the eastern frontier between Germany and Poland; this was known as the "Eastern Locarno." But the Germans refused to accept as final either the régime imposed on Danzig, or the Danzig corridor, or the division of Silesia, and the British Government did not wish to undertake to intervene in eastern Europe. Germany merely gave up her claim to go to war to alter the frontiers. She concluded treaties with Poland and Czechoslovakia which submitted all their differences to arbitration; France, by a separate instrument, promised to guarantee them.

The admission of Germany to the League of Nations, proposed at a special meeting at Geneva in March 1926, was delayed by the opposition of Spain and Brazil, who wished to take advantage of the occasion to gain for themselves a permanent seat. The admission of Germany was decided at the session of Sept. 1926. The German foreign minister, Stresemann, took his seat on the Council, where he used his influence in 1927 in the direction of peace and disarmament. Germany had re-entered the Concert of Europe, as France had done in 1818; but she remained under special obligations by the occupation of her territory and the limitation of her military, naval and air forces.

The success obtained by the system of guarantees in the direction of security diminished resistance to schemes for disarmament. Negotiations began again for the "general limitation of the armaments of all nations" promised to Germany at the Treaty of Versailles, and recognized as necessary by Article VIII. of the Covenant of the League. A preliminary meeting at Geneva, Nov. 1927, in which a Russian Soviet delegation took part, set up a commission to report on the conditions for a reduction of armaments.

The autumn session of the League of Nations, 1927, was held in a calm atmosphere. The representatives of Poland and Lithuania, countries in a condition of permanent conflict, declared at Geneva, in Dec. 1927, that their countries were not in a state of war, although Lithuania continued to claim Vilna. The year 1928 opened without grave disagreement in any part of Europe. The Little Entente limited itself to protesting at Geneva against the illegal importation of machine guns into Hungary. Russian revolutionary propaganda was diminished by disunion among the communists.

But the conflict between Poland and Lithuania, continued in spite of the intervention of the League of Nations and was only settled by the Königsberg conferences. In the South Ahmed Zogou, considered as the agent of Italian politics, was proclaimed king of Albania (August) which prejudiced the re-establishment of friendly relations between Italy and Yugoslavia. On the other hand the international atmosphere was lightened by the combined effort of the great Powers in favour of peace. The Kellogg Pact

by which the contracting parties were pledged to renounce war as a political instrument, was signed on Aug. 27, in Paris by the United States and the majority of the European Powers. The 9th Assembly of the League of Nations in Geneva discussed in a pacific spirit the evacuation of the Rhinelands and the Polish-Lithuanian conflict, and the president of the Preparatory Commission for the Limitation of Armaments was invited by the Council of the League to be ready to convoke the commission "in any case" at the beginning of 1929. The favourable impression was, however, a little decreased by the criticisms made by the United States on Sept. 29 on a Franco-British agreement referring to the limitation of war navies, and which American opinion considered directed against the United States.

On Feb. 11, 1929, a treaty was signed between the Vatican and the Italian State, which put an end to the discord of nearly 60 years, and restored to the papacy its states as a sovereign power over a small area of Rome—"The city of the Vatican." See further especially the article PAPACY and also ITALY, PIUS XI., VATICAN, etc.

BIBLIOGRAPHY.—*Cambridge Mediaeval History* (1923–27, bibl.); *Cambridge Modern History* (1901–12, bibl.). It is neither possible nor useful to indicate all the documents and works relating to all the questions dealt with in the present article; they can be found in the bibliographies annexed to each of the articles to which they refer. It is sufficient to indicate certain general works. They are, in addition to the Cambridge histories above cited: Th. Lindner, *Weltgeschichte*, 8 vols. (1901–14), a clear, judicial and well-informed account; *Periods of European History*, 8 vols. (1893–1901), each volume by a different author, a good popular account; E. Lavisse et A. Rambaud, *Histoire generale du IVe siecle à nos jours*, 12 vols. (1894–1902, with bibl.), written by a large number of authors of varying ability.

For history after 1815: A. Stern, *Geschichte Europas seit den Wiener Verträgen von 1815, bis zum Frankfurter Frieden von 1871*, 10 vols. in three series (1894–1924), the most complete and scientific account; C. Seignobos, *Histoire politique de l'Europe contemporaine*, 2 vols. (7th rev. ed., 1925–26), deals with the period 1814 to 1914 (detailed bibl.). For England, the *Cambridge History of British Foreign Policy*, 3 vols. (1922). On the recent period, G. P. Gooch, *History of Modern Europe, 1878–1919* (1923).

For the post-war period the chief documents are collections of documents from archives, for the most part published by different Governments and accounts by statesmen or generals, published in the form of notes, memoirs or correspondence. The enumeration of such documents and works will be found in the bibliographies attached to special articles relating to the World War, Versailles, and the League of Nations. (C. SE.)

INDUSTRY AND TRADE

It is a curious and regrettable fact that much less comprehensive information is available concerning the industries of Europe than about those of more recently developed industrial areas of the world. Thus it is easier to obtain a picture of the state of industry in North America, Australia, New Zealand or South Africa than it is to follow the sequence of events in the continent where modern industrial organization began.

It is not proposed in this article to describe the condition of individual industries in any detail or to trace the vicissitudes through which any particular trade has passed, but rather to show first, the importance of industry as distinct from agriculture or other activities to the whole economy of Europe, secondly, the place which Europe holds in the industry of the world, and thirdly, the character and causes of the broad changes which occurred in the period 1913–28.

Although Europe is the cradle of modern industry, and looks to North America and Oceania for so large a proportion of her food supply, actually a much larger proportion of her population is engaged upon agriculture and fishing than in either of these two areas. There are indeed only five countries in Europe—the United Kingdom, Germany, Belgium, Holland and Switzerland—where industrial workers and miners outstrip in numbers the agriculturists. Indeed, so far as the daily activities of her citizens are concerned, England and Scotland are the only European countries where industry plays an overwhelmingly important rôle. In England and Wales 47·2% of the total population are directly dependent on industry and mining and only 6·8% on agriculture and fishing (1921 census); in Scotland the comparable figures are 47·3 and 10·1%. In Belgium, the most highly industrialized country after Great Britain, nearly a fifth of the population is engaged upon agricultural pursuits. If a map were to be drawn of Europe in which each country was shaded according to degree of its industrialization, the depth of shading would be found to diminish with remarkable regularity from the dense blackness of Great Britain in the north-west to the lightest of greys in the east and south-east. Switzerland, it is true, is more highly industrialized than France, and in the three Scandinavian countries the normal order is reversed, but the exceptions to the general rule are few as the following figures illustrate:

Percentage of Population Engaged in Industry and Mining

Group I.	Belgium, Germany, Gt. Britain, Switzerland .	Over 40%
Group II.	Czechoslovakia, France, Holland	Over 35 and under 40%
Group III.	Austria, Sweden . . .	Over 30 and under 35%
Group IV.	Denmark, Italy, Norway, Portugal	Over 20 and under 30%
Group V.	Hungary	Over 15 and under 20%
Group VI.	Bulgaria, Estonia, Finland, Latvia, Lithuania, Poland, Rumania	Under 15%

While the east and west of Europe interchange foodstuffs and manufactured goods between them, Europe produces more manufactured goods and less agricultural products than she requires. In the 19th century her industrial supremacy was undisputed, and not only did raw materials flow from all parts of the world to be worked up in her factories, but she herself was the greatest producer of coal, minerals and many other of the raw products she required.

Europe as Producer.—In consequence, on the one hand of the rapid development of other parts of the world, the growth of their populations and the discovery of new sources of supply, and on the other of the check which the World War caused to European progress, that supremacy is no longer undisputed. Unfortunately it is not possible to measure Europe's position in world industry as we can measure it approximately in world trade, but some indication of her relative importance as a producer of raw materials may be obtained and some notion of the relative rate of industrial evolution in Europe and elsewhere may be conceived.

For the first purpose may be employed the indices now compiled annually by the League of Nations of the production of certain groups of raw materials. They do not, it is true, embrace all products or the production of all countries and the share of Europe in world output is no doubt somewhat exaggerated. The most important lacuna in the figures is caused by the lack of agricultural data for China. But by comparing the position in two years separated by a sufficient interval of time and by giving at the same time the figures for North America, it is possible at once to see Europe in perspective and to ascertain the character of the changes which have taken place.

Relative Contribution to Aggregate Production

	Europe		North America		World
	1913	1926	1913	1926	
Cereals and other food crops .	46·2	43·3	19·6	20·5	100
Colonial produce, tobacco, hops, etc.	13·7	11·7	14·6	13·4	100
Vegetable oil materials . .	22·6	17·2	18·0	16·2	100
Textiles	16·9	16·7	30·2	33·1	100
Wood-pulp	55·3	46·6	43·9	49·7	100
Fuels	48·0	37·8*	44·9	50·6*	100
Metals	52·1	40·7*	41·5	40·6*	100
Chemicals (Fertilizers) . .	54·9	57·7	15·1	10·9	100
Total production . . .	42·7	36·2	26·1	29·7	100
Foodstuffs	45·6	42·3	19·6	20·9	100
Raw materials	38·6	28·7	35·1	40·3	100

*1925—European production in the following year was seriously affected by the British coal dispute.

The first fact brought out by these figures is the magnitude of European production even after taking into account that most of China's agricultural output is omitted; the second is the decline in her position since 1913. This decline, moreover, has been greatest exactly in those industries, coal-mining and metallurgy, upon which her prosperity in the 19th century was so largely based. In textiles, thanks to the development of artificial silk manufacture, she has nearly maintained her position; in chemicals, as a result of the very rapid progress achieved in the manufacture of azotic fertilizers, she has improved it; but on balance her contribution to the total value of the output of the materials considered has appreciably diminished.

These figures must not, of course, be interpreted as giving Europe's contribution towards total industrial output. They relate either to the products of the soil or subsoil, such as cereals, flax, coal, etc., or such crude or partly manufactured articles as pig-iron, wood-pulp, artificial silk yarn, etc. Nor must it be presumed that she is necessarily poorer because her share in the world production of these foodstuffs and raw materials is smaller than it was. Actually her index of raw material production was slightly higher in 1925 than in 1913. The change in her relative position was due to the rapid progress achieved elsewhere, as is shown by the following figures:

Indices of Production—1913=100

	Europe*	N. America	Asia†	World
Textiles	143	141	125	128
Wood-pulp	154	207	..	183
Fuels (1925)	91	130	159	116
(1926)	80	143	157	116
Metals (1926)	89	146	163	119
Fertilizers	142	178	285	136
Total foodstuffs and raw materials				
(1925)	102	128	121	116
(1926)	98	132	122	116
Total raw materials				
(1925)	98	133	147	122
(1926)	93	144	150	125

*Includes the whole of U.S.S.R. †Excludes Asiatic Russia

In 1925 many countries in Europe were still suffering from the effects of inflation or the commercial depression which frequently follows on currency stabilization. In 1926 British industry was prostrated by the protracted coal dispute. In spite of these temporary difficulties production of basic products was during these two years just about at the pre-war level. But in North America it had increased by over a third and the net value added in manufacture by very considerably more. After the autumn of 1926 a rapid advance was made in Europe, well beyond what had ever been achieved previously. But in the interval between 1913 and these later years a very great change had taken place in the relative importance of different industries—a change which is illustrated by the indices for textiles and wood-pulp on the one hand, 143 and 154 respectively, and those for fuels and metals, which were only about 90. To some extent these changes are typical of what had been happening elsewhere. Thus the world fuel and metal indices are much lower than the others given. But European industry has undergone and is undergoing a change which is in many respects exceptional. The competition of countries more recently industrialized, changes in commercial policy, new scientific discoveries and a number of other factors have weakened the demand for the products of what were formerly her basic industries—coal-mining, heavy metals, shipbuilding, cotton spinning, etc., and directed capital and labour into other channels. The magnitude of this change can be gauged to some extent from the individual indices of certain countries and by splitting certain of the indices given above into their component parts.

Not many countries supply current and complete information concerning even their leading industries, but the tendencies of trade in Great Britain, France, Sweden and Russia can be traced. Thus, in Great Britain in 1927 the iron and steel index averaged 91·5, the shipbuilding index 71, that for cotton 78·8, that for tobacco 130·8, for paper 145·8. In France the general industrial index in 1926, owing to the export premium which arose from exchange depreciation, stood as high as 125, while the metallurgical index, which was appreciably higher than in most other European countries, was well below the general average at 113, and textiles were as low as 94. In Sweden in the same year paper averaged 162, the chemical industry 144 and all industries 123. In Russia, in the commercial year 1926–1927 the heavy industries averaged 86 and the light 119.

Such data as exist for the whole of Europe give similar results. The recovery and development of the newer and smaller industries have been much more rapid than in the case of what were considered the major European industries at the end of the 19th century:—

Industrial Production in 1925; 1913=100

	Europe	North America	World
Coal and lignite (in terms of coal)	91	101	98

*1924. †1926

In most cases the year 1925 has been chosen as more characteristic for Europe than 1926. Since that date there has been a very rapid development in certain countries, and by 1927 European production of coal and raw steel was over 100 per cent of that in 1913. But complete later figures are not available and those given bring out very clearly the character of the changes which have been taking place. All the heavy industries have suffered either from absolute weakening in demand or from over-capitalisation, an excess of plant laid down for war needs. The general service textiles, cotton and wool, owing to somewhat different causes, have suffered likewise. On the other hand new industries have grown up and industries which were previously of minor importance have greatly expanded. The tendency for lighter goods to replace the heavier, and for the more expensive the cheaper, is illustrated to some extent in the table. But, in fact, the movement is more radical and comprehensive than is suggested by the figures quoted. Thus, not only have artificial and natural silk replaced cotton and even wool to some extent, but within the cotton industry finer counts are being spun and in the woollen more merinos and crossbreds and less shoddy and coarse wool are employed. Similarly in the metallurgical and engineering industries, while the heavier branches have suffered, the manufacture of lighter machinery has developed and the motor-car industry has made vast strides. The internal combustion engine has for many purposes displaced the steam engine; aluminium has displaced cast iron for hollow ware; knitted goods have displaced woollen cloth, etc.

Of the recent technical changes perhaps the most revolutionary are concerned with the means of transport and the electrification of industry. Europe has directed large amounts of capital which might previously have been utilized for railways or other purposes necessitating the use of the products of the heavy metal industries to the construction of roads and is gradually substituting electric power for the direct employment of coal as fuel.

The Most Prosperous Industries.—But during the years immediately following the armistice, Europe was busily engaged in

repairing war damage, and much capital was sunk in the improvement of land, the reconstruction of towns and villages and the re-equipment of factories. There has thus been a greater expenditure on capital account than the bare statistics of basic industries portray. It remains nevertheless true that the industries which have prospered the most, apart from a few exceptions are rather those manufacturing goods for immediate consumption—the motor-car industry, hosiery, the manufacture of boots and shoes, of confectionery, of tobacco, of paper, etc. A number of factors have contributed to this result. During the years immediately succeeding the war, the national income of most European countries was reduced, and less was available for saving. The hazards of war and the storms of inflation weakened the will to save. The change in the distribution of wealth in favour of unskilled labour at the cost of the landlord and the middle classes hindered capital accumulation. Further, the international flow of capital was checked by currency instability. It is not necessary to deal here with all the complications to which inflation and deflation gave rise. From 1918 to 1925 unsound monetary conditions were without doubt the most important of all the hindrances to European industrial recovery. They had, however, one secondary effect which is likely to prove of longer endurance, for they contributed in a number of ways to the erection of those tariff walls which have helped to divide Europe up into a number of more or less water-tight compartments. The economic nationalism which has characterized post war commercial policy has further enforced the tendency in favour of the development of the smaller and newer industries. The endeavour of each State to make itself economically independent has led to the erection of new plant in a number of markets which were previously supplied from abroad. Thus has there been a double shift in the centre of gravity: first, away from the staple industries towards new activities, and secondly, away from the large existing agglomerations of plant and equipment towards new plant in less highly developed countries. Both tendencies have resulted in much existing plant being left inactive. Other influences beyond European control have worked in a like direction. Thus, the growth of industry in the countries in which the raw materials are found, stimulated by the war and fostered by tariffs, has weakened the extra-European demand for many and more especially for the coarser products of European factories. A particularly striking example of this phenomenon is afforded by cotton spinning; Japan and the United States consumed in the commercial year 1926–27 about 3½ million more bales of raw cotton than immediately before the war, and Europe about 1¼ million less. But while Japan, China, India and Brazil are able to meet their needs in coarser cotton products to a much greater extent than heretofore, the quality of European production has improved and its consumption of fine Egyptian cotton risen.

European industry has been affected, then, by lack of new capital and in certain directions excess of existing plant, by the vagaries of currencies and of taste, by the impetus which the war gave to the industrialisation of countries which for a time were unable to satisfy their needs in the markets on which they had previously relied, by tariffs, prohibitions, transport difficulties and all the other impediments to trade on the construction of which so much ingenuity has been spent. There has been a process of disintegration and new growth. But simultaneously there has been a tendency towards reintegration. The war promoted, and indeed rendered imperative, collective bargaining between the State and industries whose products were required for war needs, and thus stimulated the formation of industrial associations in all belligerent countries. The peace treaties in many cases divided the members of these associations from one another by new lines of frontier. The difficulties of the situation forced the leaders of industry to collaborate in seeking a solution of the problems which arose. Modern European industrial organisation is thus characterized by the concomitant growth of industries new in kind and in place and the association of industries, old and new, into powerful international combinations.

Nature and Volume of European Trade.—The attempts made by the great majority of European countries in post-war years to foster domestic industries have inevitably affected both the composition and the quantum of European trade. The proportion of the total goods produced which are exchanged internationally has diminished despite the fact that with the foundation of new States the number of trading units has increased. But the continent as a whole is necessarily dependent on outside sources of supply for many of her raw materials and is not self-sufficing in foodstuffs. The changes which have taken place in commercial policy therefore have not been sufficient seriously to modify the essential characteristics of her international trade. Europe remains necessarily a buyer of raw products and seller of manufactured goods. In some respects recent scientific progress has rendered her less dependent on foreign supplies; thus artificial silk is manufactured from indigenous timber, nitrogen is obtained from the air of Europe instead of the deserts of Chile, and the enormous capital expenditure on roads has necessitated the import of no raw materials from extra European lands. But on the other hand the demand for petroleum in which she is not self-supporting, of rubber, of vegetable oils and fats has greatly increased and with the growth of her population her purchases of bread-corn have likewise gone up.

The composition of the trade of the individual countries varies widely and roughly in accordance with the occupational division of the population illustrated above. A number of countries publish figures of their trade divided into five large groups of products, namely, (i.) live animals, (ii.) articles of food and drink, (iii.) materials raw or partly manufactured, (iv.) manufactured articles, (v.) gold and silver. These countries may with advantage be arranged in the order of the relative importance of their exports of manufactured goods.

Imports and Exports by Groups of Commodities

The selection of countries given is sufficiently characteristic of Europe as a whole to bring out the essential facts and to throw in relief the devotion to industry in the north and centre of Europe, and the importance of agriculture in the east and south-east. The imports of Europe are much more evenly spread amongst the second, third and fourth groups than are the exports. A third of the imports of Switzerland, one of the most highly industrialised countries in Europe, consists of manufactured articles, and over a third of those of the Netherlands and Sweden. This contrast between imports and exports is of course an almost universal phenomenon. Countries, like individuals, tend to earn their income by devoting their attention to a restricted number of activities and to spend it on a wide range of objects. But as a characteristic of European trade it is of vital importance. For as industries develop in other parts of the world, Europe's prosperity is necessarily dependent upon the demand by manufacturing States for manufactured goods. Her trade, as her industry, is accordingly tending to concentrate more on highly finished goods and articles of high value demanding an exceptional degree of skill in the process of their manufacture.

Exports of coal, of unbleached cotton piece goods, of railway material, have shrunk and British trade has been particularly

adversely affected. Both in the United Kingdom and elsewhere the products of the newer industries, of the most expensive goods, of luxury goods, have increased their importance. Thus manufactures of silk, paper, motor cars, scents and soap constitute an increasingly important share of French exports; electro-technical goods of German exports; silk piece goods, fine cotton tissues and motor cars of those of Italy; diamonds and plate glass of those of Belgium. The examples are selected almost at random. The tendency they illustrate is common to nearly all the more advanced industrial States of this continent. It has been intensified by the war, but is nevertheless a natural development. It was to be expected that the power of countries beginning on an industrial career to compete with Europe should have been greatest in respect of the coarser grades of goods. The advantage they derive from cheaper labour or cheaper raw materials could only be countered by methods of mass production—methods whose success is greatly dependent on a large home market. But European markets are fenced about with customs, tariffs and with a few important exceptions Europe produces relatively short lines of goods intended to meet the needs of a medley of consumers in all parts of the world and designed to penetrate through what gaps may be found in the tariff walls which have been erected. Further, as all continents in the world grow in wealth, the demand for superior European products mounts automatically.

Before the war Europe probably accounted for over 60 per cent of the total trade of the world. In 1926 her share had fallen to under one half. This diminution of her importance has been due in part to an absolute reduction of the quantum of her imports and exports and in part to the very rapid development of the far east and the United States of America. Within Europe the most serious factor has been the partial severance of Russia from the other trading nations of the world. But in the whole of central and eastern Europe the international interchange of goods is on a much smaller scale than it was for instance in 1913, although it is just in this part of the continent that the new states have been set up. In order to understand the changes which have taken place it is necessary therefore to divide the continent into large groups of countries and consider these groups separately.

Territory	Imports			Exports			Total		
	1913	1925	1926	1913	1925	1926	1913	1925	1926
A. Eastern and Central Europe:									
Excluding Russia (U.S.S.R.)	17·8	15·3	13·2	17·4	12·3	13·7	17·6	13·9	13·4
Including Russia (U.S.S.R.)	21·4	16·6	14·3	21·6	13·4	14·9	21·5	15·1	14·6
B. Rest of Europe*	40·2	37·9	37·4	33·6	30·7	29·0	37·0	34·4	33·3
C. Europe, excluding Russia (U.S.S.R.)*	58·0	53·2	50·6	51·0	43·0	42·7	54·6	48·3	46·7
D. Europe, including Russia (U.S.S.R.)*	61·6	54·5	51·7	55·2	44·1	43·9	58·5	49·5	47·9
World	100	100	100	100	100	100	100	100	100

*Excluding the Netherlands, owing to incomparability of pre- and post-war statistics. The inclusion of the Netherlands would raise the percentages for Europe, including Russia, in 1925 and 1926 to: imports 55·9 and 53·2; exports 45·3 and 45·2; totals 50·8 and 49·3.

While Europe's share in world trade has fallen off that of North America has risen from 14% in 1913 to 19% in 1926 and that of Asia from 12% to 17%.

Europe's Share of World Trade.—The change which has taken place is, however, more profound than might at first sight be believed. Europe's share in world exports has contracted more than her share in world imports. In 1913 the excess of imports over exports represented very largely goods obtained in payment for the interest owed by countries to which Europe had lent capital. During the war much of that capital abroad was lost or sold for goods required for immediate war-time consumption, so that Europe's claim on other parts of the globe was seriously diminished. By 1926 the position had been reversed and many European countries were borrowing from the United States of America and paying interest on previous loans. Their borrowings were however very much greater than their interest payments, exceeding them probably by some £100,000,000. The excess of imports over exports in that year therefore was composed largely of goods purchased out of the proceeds of capital borrowings. It may be expected that within a relatively short space of time Europe's borrowings will fall below her obligations on account of interest and amortisation of debt and that in consequence her exports will increase relatively to her imports, and both the direction of her trade and the average level of her prices profoundly modified.

Although there is no reason to believe that the net production of European industry is lower than it was before the war, the quantum of her trade, if that term may be employed to express volume in terms of stable values, would appear in 1926 to have been still about 10% less than in 1913. The following figures show the relative position of the same groups of countries as were employed above:

Percentage Changes in Quantum of Trade 1913=100

Territory	Imports		Exports		Total trade	
	1925	1926	1925	1926	1925	1926
A. Eastern and Central Europe:						
Excluding Russia	92·8	82·6	75·6	86·0	84·1	83·4
Including Russia	83·7	74·3	66·7	75·1	75·1	74·5
B. Rest of Europe	101·3	102·8	98·1	94·2	100·3	99·3
C. Europe excluding Russia	98·7	96·5	90·4	90·8	95·1	94·5
D. Europe including Russia	95·4	93·1	85·9	86·7	90·6	90·3
World	107·8	111·1	107·1	108·5	107·4	110·3

Russian trade is growing, but in 1926 was still less than half of what it had been in 1913. With the gradual restoration of settled conditions in the other countries of central and eastern Europe trade throughout the whole of this area steadily develops—impeded though it is by high tariffs and frequent changes in rates of duties. The rest of Europe by 1926 had just about got back to the pre-war level, a proof, since foreign trade has become less important than domestic, that the total production of goods had risen above that level. The neutral maritime countries, Denmark, Norway, Sweden, Spain, etc., have achieved the greatest progress; and the first three countries, with Holland, have pursued the most liberal commercial policy. (A. Lov.)

MINERALS AND INDUSTRIES

The modern period was inaugurated by the exploitation of coal and iron for steam-driven industry, England for long leading in this development. In the last quarter of the 19th century the predominance of British industry was strongly challenged by Belgium, Germany and the United States of America, and with the coming of the 20th century, electrical power, whether from waterfalls or from coal and the use of gas and oil engines diminished England's initial advantages seriously. The mid-Victorian form of the doctrine of Free Trade, with its consequences of high-specialization on the part of different countries in different activities, was not attractive to Continental States anxious lest economic dependence upon neighbours or possible enemies might interfere with political freedom. The idea grew up of States producing within their borders as much as possible of the manufactured goods they need, and developing an export trade in certain industries in which they might have special advantages. The repercussion of this movement upon Britain has been a marked feature of British life in the last ten years, during which efforts have been made in many industries to safeguard the British markets for British products. The conflict between the idea of a British market preserved for British goods and the idea of Britain as a centre of large scale industry for export purposes is one of the standing problems of British life; and solutions are sought by compromise rather than by planning on one or other line.

The coal and iron industries of Europe have developed a zone of dense population along the northern bases of the central hills of Europe, from Flanders to Poland, and in that zone many great industrial centres have grown in what had already long been

famous cities, often at the exit of valleys from the broken lands of central Europe. The greatest coal producers, in sheer quantity, are Britain and Germany, half the German production being lignite, formerly considered inferior but now recognized as of value for special purposes. France, Belgium, Czechoslovakia, Poland and Russia also produce large amounts of coal, and Spain, south-east, Holland, Austria, Hungary and Yugoslavia a certain amount. Quantities of less than three million tons per annum are produced in a number of States. The development of coal mines in the Belgian Campine and in Dutch Limburg, the opening of the Kent coalfield and the development of the Doncaster area in England, and the rehabilitation of the French coal mines after 1914–18, are outstanding recent features.

The production of iron was at first predominant in England, but the situation changed, especially with the invention of methods for extracting the iron from the *minette* of Lorraine, which has now become the chief source of the metal on the Continent, Europe, as a whole, being behind the United States of America in iron production. With the re-entry of Lorraine into France that country has become the leading producer of iron in Europe, with Luxembourg and England a long way behind. The change of political frontiers has reduced Germany to a minor position in iron production, though she has the coal and the skill for the industry. Iron production in Sweden remains important, thanks to the superior ores found there. Spain, Austria and Czechoslovakia produce a certain amount of iron, and so does Russia. The large iron industry in Belgium depends mostly on Luxembourg for its raw material, and international co-operation between Germany and France is of the utmost importance to the German ironworks. Vein-minerals, especially copper, are produced chiefly in the Iberian peninsula and Germany, as also are lead, manganese and zinc. Austria is also of some importance here. Some gold and platinum are produced in Russia, and silver in Germany, but the Continent is not rich in the precious metals.

Salt has long been of economic importance, indeed many a prehistoric site of the Late Bronze or Early Iron age is near salt and seems related to salt supplies. The regulation and taxation of salt supplies have exercised Governments throughout the historic period, and this attention on the part of rulers demonstrates its special value to mankind. Europe is specially fortunate in having large salt supplies, which are specially important in England, Germany and Poland. Potash compounds are obtained in large quantities in central Germany, and also in France now that the potash deposits of Alsace are within that country once more.

The old predominance of Britain in the textile industries has gone. Customs boundaries in Europe have multiplied, and many States are trying to develop these industries for themselves. Moreover, the introduction of wood pulp industries, both for artificial silk and for paper, has given advantages to countries with forests for pulp and waterfalls for power, features which often go together. Further, Holland, as a neutral in the war of 1914–18, has gained very greatly in industrial importance, especially in the making of textiles (both cotton and artificial silk). Italy, with long experience of natural silk, leads, in Europe, in the production of artificial silk, though its total is far below that of U.S.A. Germany and England follow, and France, Belgium and Holland also produce the material largely, the production of the two latter being remarkable for the size of the countries.

Motor-cars, oil- and gas-engines, and the use of electrical power, have altered the distribution of the manufacture of fine machinery, and south Germany, Switzerland and north Italy have profited specially in this sphere. The spread of rubber industries is another recent phenomenon. The term chemical industries has come into use to cover a large range of works based upon applications of chemical science working upon mineral salts, vegetable oils, and a variety of other materials. The high development of scientific education in Germany has given that country a leading place in chemical industries, but Britain has organized herself in this matter and in that of the production of dye-stuffs in the last few years, and many countries are taking part, in varying measure. The growth of industries in ports to which are brought copra, palm oil, earth-nuts, rubber, etc., from the equatorial regions is a notable feature of this century, while the supply of electric power has promoted the distribution of industries along railway lines, as west of London, not necessarily near coalfields.

POST-WAR REORGANIZATION

The adaptation of former armament works in Germany to industrial production after 1918, and the reconstitution of the German mercantile fleet, and the re-growth of Germany's shipbuilding industry, by a great effort of all concerned, has been a marked feature of European life since 1918. Parallel with this has been the reconstruction of the ruined regions of northern France and their equipment for modern industry on a large scale; this region needs supplies of fuel from Belgium and Germany. The renovation of Belgian industry has been very marked, and Antwerp has recovered and expanded, while there has been great expansion of Dutch textile and other industries. The northwestern lands have felt the crisis of 1914–18 in other ways. Sweden, with her own supplies of high grade iron and timber, was able to maintain her position throughout the crisis, and in the subsequent period of financial upheavals. Norway lost a proportion of her mercantile fleet through submarines and mines, and both her carrying trade and her exports and imports were seriously interfered with. The reorganization of trade and finance after the war has been difficult, and the Norwegian mercantile marine, formerly among the largest in Europe (after Britain and Germany) has been outstripped in size by those of several other nations; it was naturally of importance when wooden ships were in general use. Denmark lost a proportion of her cattle in 1914–18, partly through difficulties about fertilizers and feeding stuffs, and her entrepôt trade at Copenhagen is not what it was under pre-war conditions. Also, industrial depression in Britain, and the competition of New Zealand in the supply of dairy produce have limited Denmark's chief market. On the whole, therefore, the north-west is somewhat less prosperous than formerly, while the low countries seem to have gone ahead markedly. Switzerland has been in a strong position throughout, but had to face special difficulties when the currencies of all surrounding countries were heavily depreciated and subject to daily fluctuations. The progress of the electrical industry and of the utilization of electrical power is a leading feature. The struggle of Austria, left with a historic city of nearly two million people in a small and rather poor State, has been and still is a severe one; it is increasingly recognized that Vienna is needed by Europe as a whole, and if the Main-Danube, Elbe-Danube and Oder-Danube ship canal schemes should mature, the great city would have to play a very important part once more; every re-growth of international links is likely to profit Vienna, but the new and strong Czechoslovakian State is naturally inclined to use its own Bratislava (formerly Pressburg) as outlet towards the Danube. Czechoslovakia, in the fortunate position of combining strong agricultural, industrial and cultural traditions under able leaders, has advanced remarkably since its birth in 1918; the other new States have nearly all found serious political difficulties and, in several of these, the loss of the old aristocracy and the parcelling of the land among peasant proprietors has thus far brought a diminution of harvests. Finland, with its timber, has prospered considerably.

Communications.—Communications in an area of such varied and broken topography are very largely determined by physical features and, in Europe, the lines or zones of the loess (*see* above), the Elbe-Oder lines to the boundaries of the mid-Danube basin, and thence to the Adriatic, to the Vardar, to Nish, Sofia and Constantinople, and to the Black sea, have remained important since prehistoric times, while the Alpine passes and the Rhône-Rhine ways have played great parts in Roman and later periods and, among the former, the Brenner was important still earlier and had very special importance in the middle ages. This importance is illustrated by the historical development of Venice and of Innsbruck, Ulm, Augsburg, München, Ratisbon, Passau, Nürnberg and Frankfurt-on-Main north of the Alps. Many of these towns are of great industrial importance at the present time, having re-developed, especially with the re-distribution of industry and the spread of the use of electrical power in the 20th

century. But the historic route is no longer of special commercial importance, and as a way across the Alps it is now supplemented by lines of railway in other passes. The Semmering had a railway built in 1848–54, and this was continued by other passes via Caibach to Trieste in 1857; this was built before the Brenner railway. The Mont Cenis railway (altitude 4,380 ft.) was built in 1871, and is being supplemented (1928) by a line from the French side down to the Riviera. The St. Gotthard tunnel (altitude 3,785 ft.) was made in 1882, and the Simplon tunnel (altitude 2,300 ft.) in 1906. Each of these three railways has been built at a lower level than its predecessors, thanks to the growth of engineering enterprise in planning longer and longer tunnels, and the introduction of electric power for locomotives, lighting, ventilation and pumping has greatly reduced the difficulties of long tunnels. The importance of the Simplon route has been greatly increased by the cutting of the Lötschberg tunnel through the Berner Oberland, giving direct communication from the Simplon to the north via Berne and Basle. There are many other tunnels within the Alpine system, and the development of mountain railways, notably to Davos and the Engadine, has been an important feature of the growth of communications. The railway network of Europe has been made a good deal closer, the mileage of track laid having increased considerably since the beginning of the century. Electrification of railways is proceeding apace in Switzerland, France, Italy, Holland, Germany, etc. The railway systems which can be termed continental in the fullest sense include the following:

(*a*) That from Calais or Paris via Strasbourg, Stuttgart, München, Linz, Vienna, Budapest, Belgrade, Nish, Sofia and Philippopolis to Constantinople, with a prospect of organization of a train ferry across the Bosphorus to link this system with the railways of Arabia, Syria and Palestine and, ultimately, Egypt and beyond.

(*b*) That from Ostend or the Hook of Holland via Cologne, Frankfurt-on-Main and Nürnberg to join (*a*).

(*c*) That from Calais or Paris via Mont Cenis to Milan, Zagreb (Agram) and Belgrade to join (*a*).

(*d*) That from Ostend or Paris or, ultimately Lisbon or south Spain, via Brussels to Cologne, or from the Hook of Holland to Cologne, Magdeburg, Berlin and onwards, either via Vilna to Leningrad or to Warsaw and Moscow, linking with the trans-Siberian system.

(*e*) That from Calais or Ostend via Paris or Basle, or from north Germany, etc., via Basle to the Lötschberg and Simplon or the St. Gotthard, and so into Italy, or via München and Innsbruck and the Brenner, also into Italy.

(*f*) That from north Germany via Vienna and the Semmering pass to Trieste.

(*g*) That from Berlin and Vienna through Klagenfurt and the Karawanken, and the Julian Alps to Trieste, etc.

(*h*) That from Berlin via Lwow to Odessa.

(*j*) That from Oslo and Stockholm to Helsingborg and Malmö, across the Sound to Helsingfors or Copenhagen by train ferry. From Copenhagen one route via Gedser, with its train ferry to the German port of Warnemünde, giving connections with the German and general Continental systems. Another route goes across Zealand and Fünen to Jutland, traversing the Great and Little Belts by train ferry, and reaches Esbjerg, whence steamship communications give links with England, France, the Low Countries, etc.

Water transport on rivers and canals developed greatly prior to the invention of the railway locomotive, and in England it has, on the whole, lagged behind since the railway gave such added speed to movement. Canals in Britain involved much engineering and many locks, which greatly delayed transport. On the European plain, however, there were large navigable rivers, and, linking them in Prussia, natural channels between morainic hills (*see* BERLIN). The canal systems of the Rhine and north Germany are of great economic importance, but they are, as yet, not adequately united to the Danube system of navigation, for the old Ludwigs Kanal via the Altmühl linking Nürnberg and Regensburg (Ratisbon) is small and may freeze in very cold weather. A new canal, from Main to Danube, for large boats, has been planned and would make a great difference to European communications, as also would the projected canal from the Oder to the Danube via the March. The added importance of Vienna, if these schemes develop, is easily appreciated. The canal from Marseilles to the Rhône and the opening up of the Étang de Berre which is the consequence, the improvement of the Seine, making Paris an important port, the similar development at Manchester, due to the Manchester Ship canal, the Kiel canal, and the improvement of the Hamburg-Lübeck system, are important local changes of water communication in the last generation which deeply affect European commerce. Ocean-going boats of moderate size can go up the Rhine to Cologne, and very large river boats and barges get up to Mannheim; 1,000 ton barges go right to Strasbourg and Kehl, Kehl being the port on the German side of the Rhine opposite Strasbourg; at times they can even go as far as Basle. Barges of 1,000 tons can go up the Meuse to Liége; Brussels is becoming a port of some importance. The treaties of 1919 enforced international control in the case of several navigable rivers, previously belonging to the Central Powers, and, for example, gave Czechoslovakia special privileges at Hamburg and Stettin.

The revival of road-transport, thanks to motor cars and lorries, is leading to improved road systems and alterations of communications, the end of which it is not easy to foresee, but it is said that this has not yet deeply affected international commercial transport, much as it has changed tourist traffic. Air communications are still in their infancy (1928), but promise to enhance the importance of the capitals as termini at the expense of junctions near frontiers. The many, and in some cases unexpected, results of the development of telephones, wireless telegraphy and films as means of international communication are matters of common talk, and the spread of certain English or American phrases and notions through the films is very noticeable in some countries in Europe.

DISTRIBUTION OF THE POPULATION

Population—States and Towns.—The populations of the countries of Europe, according to censuses or estimates subsequent to the last census, are given in the table opposite.

Population is increasing everywhere as a result of the development of economic resources and the advance of medical science, but the rate of increase is lessening very markedly in several regions, and this is shown most typically in the decline of the birth rate, which, in England and Wales, was 16·6 per thousand in 1927, the lowest figure ever touched. The contrast between this and figures over 35 reached about 60 years ago is very striking. In Italy the diminution of death rate, though well marked, is not as striking as in Britain, and the fall of the birth rate has been much slower, the increase of population since the beginning of the century has thus been nearly 25%, and this followed an increase of some 14% in the previous 20 years. The stability of the French population, with somewhat higher birth and death rates than the British, is proverbial. The fact that the German republic, shorn of so much territory through the war of 1914–18, nevertheless has a much larger total population than at the beginning of the century is a clear indication of the immense industrial development that has occurred. Density of population in Belgium and the Netherlands has increased markedly in the 20th century, in large measure owing to development of manufactures, as discussed in the articles on those countries, but, at the moment, England and Wales together have a slightly greater density of population even than Belgium. If the above figures be added together it should be noted that they would give the population, not of Europe, but of Europe with a large area in Asiatic Russia.

The population and area of the British Isles and Italy are not now very different from one another, but the distribution of population in the two cases is very different. In the British Isles, London and Glasgow overtop the million, and at least three towns approach that mark, while seven more have over 300,000 people each, ten others over 200,000 and 25 others over 100,000. In Italy, on the other hand, the three chief cities are nearly on a level, at over 800,000 people, there are three others with over 300,000

	Year	Population	Per square mile
British Isles:			
1. England and Wales	1927	39,290,000	673
2. Scotland	1927	4,892,000	164
3. Northern Ireland	1927	1,253,000	239
4. Irish Free State	1927	2,958,000	111

*Land area

people, five others with over 200,000 and seven others with over 100,000. The contrast between the British Isles and France is equally marked, for, apart from Paris, France has one city with over 600,000, one other with over 500,000, two others with over 200,000, and 12 others with over 100,000. France has been far more successful than England in holding her rural and small town population in several regions, though rural decreases are widespread and serious. France and Italy again contrast, for Paris has as many people as Rome, Milan and Naples together, an illustration of French centralization. Germany, with Berlin and Hamburg over the million mark, and 13 others over 300,000, nine more over 200,000, and 22 others over 100,000, shows a condition of much more intense urban development than is found in France, and a larger number of towns over the 300,000 mark than have the British Isles, a reflection of the fact that in Germany there are many historic capitals of constituent States, as well as a number of great industrial centres. The number of large towns in Soviet Russia is a conspicuous feature at the present time.

Cities of Europe having over 1,000,000 people each are:—

London (Greater London)	7,791,310
Paris (Greater Paris, Dept. of Seine)	4,628,637
Berlin (Greater Berlin)	4,024,165
Moscow	2,019,453
Vienna	1,865,780
Leningrad	1,616,118
Hamburg	1,079,126
Glasgow (estimate)	1,049,000

The effective population of Liverpool, of Manchester and of Birmingham is much larger than is given in the official figures for specified areas, and they are all practically agglomerates reaching or passing the million. The same reserve should be borne in mind concerning a number of Continental cities. There is a widespread tendency towards ribbon growth of cities beyond their old limits and to a decline of population at the centre, and many diverse attempts are being made to cope with the serious disadvantages of ribbon growth along the roads by planning schemes, in which Germany has shown great foresight and understanding. It seems to be widely true of cities of over 300,000 people in western Europe that they tend towards a metropolitan character, save in certain special cases, whether they are official capitals or no.

It has been said in an earlier section that the idea of the city is far older in the Mediterranean region than in Europe farther north, indeed many a "village" in Italy has a more or less urban appearance, the tendency being to close agglomeration, often on hills, near a spring, and, in olden times, behind a circuit of walls. A dispersed population has become more and more characteristic of north-west Europe in recent centuries as dangers of local anarchy have diminished and agricultural improvements have broken down communal tradition.

In France the idea of the town is older than it is farther north and north-east, and quite a number of towns usually in charge of a bishop in the post-Roman centuries, survived the difficult prelude to the middle ages and grew again as trade and intercourse developed, from the second half of the 11th century onwards. The towns on the left bank of the Rhine, and some on the Danube, also retain a measure of continuity from Roman times, but the towns farther east are, for the most part, appreciably younger. From this cause there has arisen a difference fraught with great consequences for modern political organization. As the towns of east-central Europe grew, in many cases, long after those of the west, and grew in the midst of a rurally-minded population, they often attracted to themselves people from the west, German-speaking or Jewish people, who settled among Slavonic and other peoples of east-central Europe, sometimes in this way making a middle class that neither the aristocracy nor the peasantry has been able fully to assimilate to itself.

Attention may be drawn to a tendency to change in the town-plan from west to east. In a French town of Roman tradition, typically ruled by a bishop in the centuries following Roman decline, the cathedral is often the centre around which the market town is set, and often enough within the Paris basin there may not be any old town hall or other obvious mark of the burghers' power. On the borders of that basin, however, the historic town hall and the watch-tower are frequent features. Beyond the Rhine the old town is more often in the shelter of a castle, though the cathedral may be important here too. Going east one notes the frequent coupling of cathedral and palace within a stronghold, as at Prague and Cracow, and this idea is expressed most forcibly in the kremlins of the Russian cities. To understand the historic evolution of European town plans, however, one needs to have in mind many other evolutionary lines, notably the growth of maritime cities, with their groups of traders, as at Ypres, Bruges, Lübeck, etc. This has given a richness of public buildings and residences and a burgher pride which spread from the early trading cities of the coasts far inland.

POLITICAL REORIENTATION

Political Geography.—The city-state of the Mediterranean area has been the subject of many discussions, and here it is necessary to say only that its existence in antiquity and its revival in the middle ages were hindrances to any tendencies towards the growth of the idea of nationality in that region. On the other hand, in the Paris basin and on the English plain, with their towns growing or reviving, from the 11th century onwards especially as foci of rural areas around them, ease of communication led to a growth of a common vernacular tradition which, with military considerations to spur it, gave rise to the idea of a nation. This was, in the case of the Paris basin and the English plain, a group of people speaking one language, following one law and at first one form of religion, and inhabiting one continuous territory under one unified Government which controlled defence at least. The old unity under the Church was to some extent in opposition to the growth of national units and, in Germany, division as regards law and religion in the 16th century delayed the possibilities of growth of

unity around the common language which the introduction of printing, and especially the printing of the Bible, was tending to standardize. The cheapening of printing, and the spread of book-education to the middle classes in the early 19th century, was a contributory factor, alongside of a natural resistance of peoples to the enforcement of unity by Napoleon, of the phenomenal rise of nationalism in modern Europe, which has found its expression in such marked fashion in the treaties concluded after the war of 1914–18. The basic factor of nationality is more and more group consciousness, and we have the attractive example of Switzerland to show that this can be strongly developed where there is neither unity of language nor unity of religion and where even unity of law is not of very ancient growth.

Hardly any nation except Sweden, Norway, Denmark, Holland and England (without Wales) had a complete unity of language before the war of 1914–18, and Wales is included with England for many political purposes, so that the claim to unity of language is not really effective, though all save a very few can understand English. France has a Breton, a Basque, a Flemish and an Allemanic-speaking region, Germany has Slavonic elements, much reduced since the war; and most of the east-central European States created after 1918 have minorities differing in language, and sometimes in religion, from the governing group. The problems of national organization are much increased as a consequence of this, for in most cases there is a lack of that feeling of security, military and economic, which so greatly helps to keep Switzerland a group-conscious unit. The Russian plain with its multiplicity of languages and customs, and the isolation of its communities in those immense areas, is difficult ground for the growth of a valid group-consciousness. It is important to note that the 19th century nationalist movement achieved the unity of Italy, and the growth of its group-consciousness of recent years has been a very marked feature of European life. The ferment of nationalism in the Balkans in the late 19th and early 20th century, and the relations of the movements concerned to political powers outside, are well known to have been among the most important factors of the war of 1914–18. While the passion of nationalism has remodelled the map of Europe, has immensely increased the difficulties of tariff frontiers in Europe, and has caused currency troubles which have shaken credit very seriously, there are abundant signs of developments in a very different direction.

There have long been international congresses of specialists in branches of learning or of education, or of public health and welfare, or of technology. In spite of post-war difficulties these are now reviving, and some nationalist enthusiasm is turning to rivalries in these activities. Of the importance of many of these congresses, both for public welfare and for international effort, too much cannot be said. The network of banking is spreading across national frontiers, and this has greatly helped in the gradual re-establishment of currencies ruined by the crisis of 1914–18. Many large industrial enterprises are increasingly spreading to most of the industrialized lands, and in some cases even to others, so as to have production behind the tariff wall. There are attempts at international arrangement in railway, canal and river transport, not always happy or successful when dictated in treaties. There are important international labour movements and movements among university students. Most of all, there are the foundations of the Permanent Court of International Justice at The Hague and of the League of Nations at Geneva, with its related International Labour organization and the many committees of the League Assembly for health and humanitarian purposes, and finally, the International Institute of Intellectual Co-operation.

These are organizations, but in addition to such deliberate efforts there is a change in mind making itself felt, a growing consciousness of the difficulties of self-sufficiency of the nation as an economic unit, of the waste due to the multiplicity of organizations in many small States for doing or making the same things. The contrast between the small production in an average European country and the large scale production possible in the immense free trade area of the United States, is one that is causing much anxious thought.

The present (1928) difficulties of international co-operation between peninsular Europe, Europe and the Russian plain, largely political, cannot be discussed here, but these difficulties are in everyone's mind, both in the nation-States of peninsular Europe and in the Soviet Union, as hindrances to the welfare of the peoples of the whole of Europe.

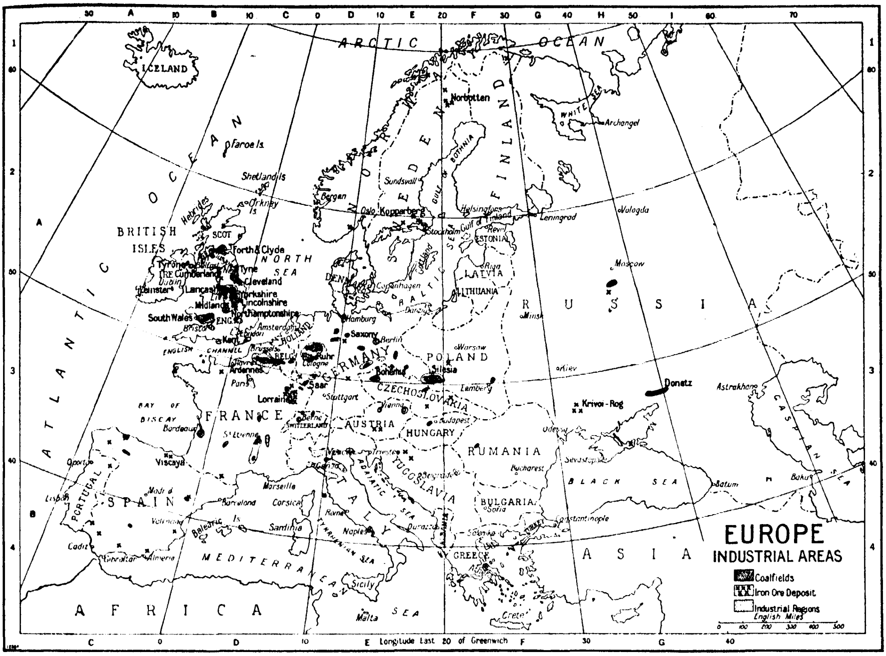
EUROPE AS AN ECONOMIC UNIT. The line of division between Europe and Asia has been obliterated by the Soviet Government. Border provinces have been amalgamated into new administrative areas which straddle the ancient frontier in complete disrespect for geographical dogmas. The exact population of Europe in 1928 is thus unknown, and the European area can only be stated on the hypothesis that reference is made to an historic and not to an actual fact. But the convention of the existence of Europe is worth preserving; the medley of races which dwell between the Ural River and Ural Mountains on the east and the coasts which face the Atlantic on the west do constitute, despite all political fissures and commercial barriers, an economic unity with a being, personality and character essentially its own.

The climate of the extreme north may be sub-arctic and of the southern peninsulas sub-tropic, but that of the great bulk of the continent is temperate; rainfall is almost everywhere adequate for the cultivation of the soil, and by far the larger portion of the ten million odd square kilometres of area is nourished by a single vascular system of rivers which flow without exception into the seas embracing the mainland, none twisting round the eastern watershed into Asia. Of the 470 million inhabitants (estimated 1928) the great majority are of Indo-European stock and of one religion. Almost all are settled tillers of the soil or fixed residents of towns. Stretching as Europe does from north of the 70th to the 36th degree of latitude, exceptions to this rule of essential unity are inevitable. Thus, the Tartars pursue a nomadic life over the arid steppes of south-eastern Russia, the Vlakhs wander unimpeded, as the seasons change, through half a dozen states; the Magyars in the heart of Europe, the Finns and Lapps in the north are of another racial stock; there is little in common between the reindeer pastures of the Russian tundra and the volcanic gardens of Naples. But these exceptions serve to emphasize the characteristic homogeneity of the whole.

Europe's Livelihood.—How, then, do these 470 million people earn their living? Europe, for all her manufacturing and mining industries, is predominantly agricultural. In only five countries do the industrial exceed in number the landworkers. The most important factors, therefore, determining the daily occupations of her population are the fertility of the soil and the character of the climate. North of a line which may be traced roughly along the river Dal in Sweden across the Baltic sea to Leningrad and the southern shore of Lake Onega and thence south-east



DRAWN BY JOHN BARTHOLOMEW & SONS, LTD.

MAP OF EUROPE SHOWING THE CHIEF INDUSTRIAL AREAS AND THEIR PRODUCTS

towards Orenburg, the predominant vegetation consists of forests. Between this line on the north and east and the grasslands of central Russia on the south, spreads out westwards the great tract of territory broken by the Carpathians and bordered by the Rhodopes, the Alps and the Pyrenees, where arable and mixed farming alternate. In the southern peninsulas, in the lower valley of the Rhone and along the Adriatic coast this mixed farming is largely replaced by the cultivation of southern fruit, by olive groves and vineyards. But vineyards spread as far north as the 52nd degree in Posen, and rye, the most important cereal in Germany and Russia, is sown in the high-lying districts even of Greece and Portugal. All the peninsulas save Denmark are mountainous, and the vast plain which is Russia and its extension over northern Germany, is divided by the folds of the Carpathians from the wheatfields of Hungary and by the folds of the Alps from the fertile valley of Lombardy. These mountain ranges of the south increase the rainfall where rain is needed, and the Carpathians protect to some extent the centre of Europe from the rigours of the Russian winter.

If the local distribution of the population of Europe be studied it will be found that its lower densities tend to vary with the fertility of the soil and the clemency of the climate, its intenser densities with the richness of the subsoil and the natural means of communication.

Thinly Populated East.—The whole forest and steppe area of the north and east, the mountain massifs and the arid plateaux of Spain contain but a minute fraction of the total population. Into the black land of central Russia and round the central coalfield projects a wedge of greater density. But even with all the industrial areas of the Donetz basin, of Moscow, of Lodz, Upper Silesia, etc., the total population of the nine countries in Europe which lie east of the 20th degree of longitude, and together account for 60% of the whole area of Europe, only comprise a little over one-third of its inhabitants. Of that third, the great majority to-day are peasants farming, since the agricultural revolution which the war ignited, their own land and producing mainly for their own needs. In the north, below the forest belt, the typical crop is rye, in the south wheat and maize. But in Estonia the main occupation is dairy farming; Northern Russia supplies two-thirds of the world's requirements of flax, and flax is the staple article of Latvian export. South of the Rhodope mountains cereals give way to vines, olives and tobacco; but in recent years the cultivation of tobacco has spread widely.

This greater eastern half of Europe produces mainly for its own needs. It exports not more than 5% of its average cereal harvest. But it forms, nevertheless, the main granary of Europe, produces a half of Europe's wheat and maize crop, nearly two-thirds of her rye and about one-half of her oats. For the industrial population of the west the surplus is too small, and over 10% of the total bread corn is imported from other continents.

Densely Populated West.—West of the 20th degree of longitude the populations are congregated in much closer masses, the greatest density being found in the valleys of the Rhine and the Scheldt, on the lower reaches of the Thames and between Birmingham and Bradford. Though in the whole of this area there are no tracts of land comparable at once in fertility and size with the black soil of Southern Russia, the tillage is more scientific, the production per hectare, save in the Iberian peninsula, is higher and the organization of agriculture more nearly approaches that of industry. The wine of France, the sugar of Germany or Czechoslovakia, the butter and bacon of Denmark, the cheese of Holland, are all produced with the aid of an elaborate

economic organization which more closely resembles the business mechanism of industry than the primitive labour of the eastern peasant. The higher output per hectare and the higher average value of the crops produced enable the land to carry a heavier population than elsewhere. But in these countries the proportion of land to total workers is with but few exceptions relatively low. In agriculture, unlike industry, machinery directly and continuously competes with labour after a certain stage of efficiency has been reached, and while the growth of industry has attracted labour to the towns the increased use of mechanical appliances on the land has tended to reduce the demand for labour. To some extent this tendency has been counteracted by other forces. The demand by towns for vegetables and fruit, as in Belgium and round almost all the great industrial centres, has gradually converted agriculture into horticulture, while the laws of inheritance in France and elsewhere have led to the incessant sub-division of properties and impeded the use of mechanical processes. But throughout western Europe, with the possible exception of France, the march from village to city has been uninterrupted. In Europe, indeed, the towns have grown up from the country-side, while in more recently colonised lands, after the first few years of struggle, the circle of cultivated land has slowly expanded as demanded by the increasing population of the towns.

Across the whole of the alluvium deposits of the North German plain rye and oats predominate, intercepted in the richer river valleys by wheat and alternated with potatoes and sugar beet. Czechoslovakia is a transition land where rye and wheat and potatoes compete on almost equal terms; in the Valley of the Danube rye gives way to wheat and after its junction with the Drave wheat in its turn is alternated with maize. West of the Rhine, the hardier cereals almost disappear to be replaced by wheatfields and vineyards, by mulberry groves in the south of France and the Lombardy plain, by olives and rice in Italy and Spain, and by oranges and lemons along the Mediterranean littoral.

The southern littoral is devoted to fruit trees, much of the northern to pasture land and dairy farming. Denmark, Holland and Estonia are essentially dairy countries, Great Britain is the greatest breeder of cattle for stock and beef, and after Russia the owner of the largest flocks. But elsewhere sheep are to be found in the largest quantities, not on the fat pastures of the valleys, but on the mountain slopes moving with the seasons, on the high uplands of Spain, on the Carpathians and the Apennines.

Europe Does Not Feed or Clothe Herself.—Europe produces a quarter of the world's supply of wool, a half of its crop of wheat and oats, over nine-tenths of its rye, two-thirds of its barley (excluding China's production). But she does not feed herself or clothe herself. The denser agglomerations of her population live not by the interchange of products with the agricultural area, though those areas meet the great bulk of their requirements within the continent, but by the sale of manufactured goods to all parts of the world. The raw materials exported are few—coal, wood-pulp from the north, some silk and wool, some platinum from Russia. The raw materials derived from the soil or subsoil are far from adequate for her industrial needs. But though Europe looks to other continents for her raw textiles, and rarer metals, for her vegetable oils and rubber, even for a large proportion of her hides and tanning materials, the seat of her great industries has been determined mainly by the deposits of coal and the proximity of raw products.

Of all factors determining the distribution of population, the most powerful have been the depth and availability of the coal seams and the natural means of communication. Coal is found in the great majority of European States, but Great Britain and Germany together are responsible for over two-thirds of the total supply and these two countries, Belgium, France and Poland, for nearly nine-tenths. Round the coalfields in these countries, in Lancashire and Yorkshire, in the valleys of the Sambre and the Meuse, in the Ruhr and the Saar districts, round Creusot, in Saxony and Silesia and in Bohemia, lie the great industrial centres. On the continent of Europe they are thus largely concentrated in the territories drained by the Rhine, the Meuse, the Elbe, the Oder, and their tributaries, and it is in these valleys that the density of population is thickest. Indeed, their only serious rivals are the rich Lombardy plain with its centre at Milan, and the scattered points constituted by the great capitals Paris, Berlin, Stamboul, and the volcanic oases in Southern Italy and Sicily. But none of these points can rival the Rhine valley and more especially the wealthy zone which lies between Dortmund and Lille.

Coal as a European Industrial Factor.—Coal has been and is the greatest natural factor determining the industrialization of Europe, and her greatest natural source of wealth. It accounts still for some 6½% of British exports, and of the total amount entering into international trade, Great Britain and Germany are together responsible for almost two-thirds. But only from these two countries and from Poland is there a net surplus for export. It is the magnet which has drawn the country population and all types of industry to itself. It is often cheaper to transport even iron ore to coal than coal or coke to the iron mines, and the economy in the case of other raw materials is determined jointly by their requirements of power for treatment and by their weight and bulk.

On coal and iron the European industry of the nineteenth century was based. Europe still produces about 45% of the world's supply both of pig-iron and steel, and of Europe's output over five-sixths of the pig-iron and over three-quarters of the steel are manufactured in Great Britain, France, Germany and the Belgo-Luxemburg Union. Coal and iron in these four countries lie for the main part not only in juxtaposition to one another, but near either to the sea coast or to rivers which could be and have been connected by a network of canals. Thus, to the north of the Tyne lies the Durham and Northumberland coal, to the south the Cleveland ore; in Ayrshire and the Clyde basin the black band ironstone extends to the coalfields; the iron works on the coast of South Wales were based originally on local ore and worked with local coal. In Belgium and Luxemburg, France and Germany, the main deposits lie in the basins of the Meuse and Moselle, or between the Moselle and the Rhine in Lorraine, and north to Luxemburg, in the provinces of Namur and Liège, round Saarbrücken; in the neighbourhood therefore of their greatest coalfields, and in easy access to the sea. The great inland iron works of Europe, at Creusot, in Silesia, in the Erzgebirge, west of the Ural Mountains, and south of Moscow likewise are all situated in the vicinity of coal. The works on the Donetz basin are at once near coal and near the Black sea at Rostov.

Here, too, in these valleys, where coal is mined and access to the sea is ready, many of the other major industries of Europe have concentrated, as cotton in Lancashire, round Chemnitz and the Saxon coalfield, in the Rhine valley at Mulhouse, Colmar, etc., in Bohemia; wool in Yorkshire, at Roubaix, Amiens, Tourcoing, etc., at Barmen and Elberfeld; machinery again largely round the central British coalfield, at Creusot, Essen, Krefeld, Barmen, Chemnitz, etc. Indeed an almost unlimited range of examples might be quoted.

But although coal has been the prime factor in determining the localization of European industry, it would be easy to exaggerate its importance. On the continent of Europe as a whole, industrial energy is both less specialized and less topographically centralized than in Great Britain. In France this is due in part to the fact that she has many coal mines scattered throughout the central region at Creusot, St. Étienne, Alais, Carmaux, etc. But other forces, some natural, some historical, have competed. Her woollen industry has grown up near the downs of Champagne where her flocks were fed, at Rouen within the pastures of Normandy and close to Le Havre where foreign fleeces are transshipped. Rouen, too, for its closeness to the sea, is one of the centres of cotton spinning. The mills in the Vosges, at Epinal, St. Dié and Sénones, date from the transference of the Alsatian industry to Germany after the wars of 1870. The textile industry of Lodz is an artificial creation; the silk industry of Krefeld and the cutlery of Sheffield owe their prosperity to the properties of the local water. Lyons, where also the water meets to a peculiar degree the requirements of the silk industry, is in the centre of the mulberry area; the chemical industry at Stras-

bourg has been built up on the deposits of natural potash salts. But quite apart from natural causes the whole history of Germany with its multiplicity of states and far-flung seats of learning has naturally conduced to the decentralization of industry. European industry has been built on the natural resources of the soil and the sub-soil. But it has been preserved and extended by acquired skill and technical education. The cork and wine of the Iberian peninsula, the steel or pulp of Sweden, the zinc of Upper Silesia, the attar of roses of Bulgaria, the linen of Ulster or Cambrai, even the tulips of Haarlem and the carnations of San Remo are the natural outcome of favourable local conditions. But the chemical industry of Germany has its roots in her thorough system of technical education, the scents and dressmaking of Paris spring from a national talent, as do the luxury goods and wares of Vienna. Again, the European countries which have been most successful in the manufacture of artificial silk—Italy, Great Britain, Germany and France—are not those in which the raw materials are most plentiful. The motor-car industry of Italy has been based on the skill of her mechanics, the watches and chocolates of Switzerland on native ingenuity and the absence of reasons for other occupations, and the rubber sponges of Moscow on the invention of a single individual.

Thus, the forces which have determined the character and the place of European industry have been manifold. Her industries were highly developed when the newer industrial countries were still in the process of early colonization and settlement. As these countries have gradually discovered and exploited their natural resources, a change has taken place in the economy of Europe, caused in part by their increasing competitive power and in part by the normal progress of science. Both causes have tended towards the decentralization of industry. The first because the increased competitive power of these younger countries has attacked particularly the basic industries of Europe, coal and cotton, wool and pig iron; the second because it has affected above all the means of transport and the source of power.

White Coal.—Coal is being supplanted in many countries by hydro-electric power, or itself transformed into electric energy and distributed in that form by long radii of transmission cables over an ever widening circle from the central mine heads. In Sweden and Norway, in Italy, north and south, in Switzerland, the Tyrol, in the mountains which lap round the east and south of France, in the Iberian peninsula and indeed wherever water can be harnessed, it is being employed as energy for driving the wheels of industry. Its use is bringing about a decentralization of industry dual in form, first, from the former centres dependent on the riches of the sub-soil, and secondly within the regions of hydraulic power themselves. For that power is caught here and there in scattered valleys, not concentrated as is coal.

Dispersion of Industry.—But there are other human forces at work which aid in the dispersion of industry. The desire of each country to be independent of its neighbours and the neglect of the value of agriculture by town dwellers into whose hands political power has passed have led to the obstruction of the free interchange of goods within Europe by the imposition of customs duties and the creation of industries in countries, more especially in the centre and east of the Continent, which before relied on Germany and the industrial States of the West for the manufactured articles which they required. The causes of this policy of national and rationalistic protection are many and need not here be enumerated. But amongst them there is one which is profoundly affecting both the relationship of Europe as a whole with the rest of the world and her own internal unity.

American Capital and European Labour.—Before the war the surplus population migrated to America, attracted by the natural resources of a half-developed continent, and thus maintained a certain equilibrium between the growth there of capital and the increase of population, an equilibrium at which the attraction to European labour and to national capital was maintained. Now the gates to the greatest field for emigration have been nearly closed, and the accumulations of American capital have vastly increased. The old equilibrium has been upset and American capital seeks European labour instead of European labour migrating to American capital. This change must have impeded the growth of wealth in the world, for the resources of nature on which that capital and labour may combine are more readily available and more plentiful west than east of the Atlantic. But in Europe, in the first place, it has affected the centre of gravity and in the second, brought about a radical modification of the relations of that continent to the rest of the world. The western and northern countries of the Continent were, and are again gradually becoming, capital exporting countries and it is to the south and east that American capital is tending, and must tend, to flow—to those countries in fact in which the old streams of emigration had their source. The rate of development of these countries will thus be, and is being, accelerated and the balance of the whole Continent altered.

That form of economic organization which is vaguely defined as modern industrialism has been slowly spreading from the midlands of England, where it had its birth in the eighteenth century, east to the great centres of economic activity which have been considered, and from these centres, through a multiplicity of trickling, often scarcely perceptible, streams to new basins. But it still remains true that if a line be drawn from Reval to Minsk and through Lemburg down the river Theiss to Belgrade and then west along the line of the river Save to Fiume, and across the north of Italy from Ravenna to Leghorn, south and east of that line the characteristic industry is handicraft. In Russia, Rumania and the Balkan peninsula, for all the big towns which exist, the typical centre of economic activity is the market village. The peasants clothe and feed themselves and the division of labour is between individuals, not between armies of specialized trade unions. In Italy the industrialized north has naturally affected the habit of life throughout the peninsula. Owing to the peculiar adaptability of the Italian workman to highly skilled individual effort, however, the workshop has continued to compete on equal terms with the factory. But the pressure of increasing population and the infiltration of capital from abroad are, except in Russia where other forces are at work, furthering the movement towards industrialization. The oil deposits in Galicia and Rumania likewise tend to this development. Indeed, all the petroleum fields of importance in Europe lie east of the line from Reval to Leghorn traced above. They lie in fact along the line of the Caucasian and Carpathian mountains, from Baku on the Caspian sea across the Crimean peninsula, a line which is broken by the Black sea and the Danube plain to be renewed at the Buzau-Dambovița fields in Rumania. But of all forms of energy petroleum is the most easily transported and industries, though aided by its proximity, are not tethered to it as they were to coal mines. Indeed, the influence of petroleum and its use in road transport has been rather to knit Europe more closely together as a whole than to intensify the development of isolated spots. For it has added a new means of international communication to the old network of waterways and railways, which crosses national frontiers with infinitely greater frequency than either of these. Moreover, rivers, though some of them, the Danube, the Rhine and the Elbe, may be the greatest of Europe's international highways, frequently divide while they join, and the obstruction caused by political boundaries is appreciably less for traffic by road than by rail. Petroleum again has rendered possible transport by air, which is, of all forms, the freest from artificial hindrances.

But the essential unity of any living organism is more easily apprehended by regarding it in its relations to other organisms than by studying with close inspection the cells of which it is itself composed. Europe, at the close of the nineteenth century, represented to the rest of the world a form of economic structure, which, though not unique, was uniquely perfected, instrumental in the provision of certain services upon which the other continents were largely dependent. She purchased their raw materials and foodstuffs, gave in exchange manufactured articles destined either for immediate consumption or for the further exploitation of undeveloped regions. She also provided goods largely in the form of loans, thus supplying at once the capital needed and through her streams of emigrants, the labour to manipulate that

capital. The raw products she bought, the manufactured goods she sold and lent, the labour she released were all alike carried on her vessels. Europe was thus to those outside her essentially the centre of commerce and the source of labour and capital. By the beginning of the second quarter of the 20th century these characteristics had become less striking; her services were less urgently required, partly on account of the growth of rivals to her position, partly because, as has been seen, the traits of her character had changed. Raw materials are increasingly manufactured elsewhere, North America can export capital in large quantities, the stock which Europe has planted throughout the American continent, in Australasia and Africa has multiplied, and Europe is herself borrowing abroad. But she remains the greatest centre of world trade; nearly two-thirds of the world's mercantile marine belongs to her; her foreign investments still greatly exceed those of any other continent.

Europe as Trader.—Where the great industries lie, there naturally does trade demand the most of the people's energies—in Great Britain, France, Germany, Belgium and Switzerland. But the distribution of trade and industry is not identical. The size of the seats of commerce depends on the wealth of their hinterland, but the overseas carrying trade is conducted largely by nations such as Norway and Greece, Holland and Denmark, naturally thrust upon the sea. In these countries and in those such as Austria and Switzerland which lie across the inland routes east and west or north and south, the largest proportion of the active population, after Great Britain, is engaged in trade and transport. But the services rendered vary. In London and Liverpool, Hamburg and Bremen, Rotterdam and Antwerp, Le Havre and Marseilles, the goods produced in the neighbouring factories and the raw materials required are congregated, bought and sold, unloaded and shipped. But Norwegians send their ships to collect goods in foreign ports, the Greeks both collect and trade widely themselves, Switzerland, though a centre of commerce, is essentially a transit country, Austria, though a country of transit, is essentially a centre of commerce with a network of banks and merchant houses spread over all the neighbouring States.

The mercantile marine of all the Mediterranean peninsulas is considerable, but the distribution of the products not only of Western and Central but also of Eastern Europe is largely conducted by the countries giving on the Atlantic and the North Sea, and it is in the North Sea ports that the markets both for raw products of warmer climates and the cereals of Eastern Europe centre. Thus Liverpool, Antwerp and Bremen are the central points for the distribution of raw cotton, London and Hamburg for wool, Bermondsey and Hamburg for hides; the wheat and maize of the Danube valley is graded for further distribution at Antwerp and Rotterdam. The largest international European markets for petroleum are at Liverpool, Glasgow and Swansea, the largest market for rubber at Liverpool. Of the distributing centres in the south of Europe which can claim international importance, the greatest are Lyons and Milan—the two main arteries of the silk trade.

But both in the distribution and in the overseas transport of goods, Great Britain plays a preponderant part. She stands at the Atlantic gate of Europe, unhampered by contiguous frontiers and unimpeded by artificial barriers. She stands, indeed, without the unity of Europe, attached by trade more to her Empire than to the continent—a focus of that trade, and a distributing centre not only for Europe but for the whole Atlantic. Despite her partial isolation, she represents in large measure the prototype of the economic organization to which continental Europe has tended to conform—a model it is true never exactly copied. With her extraordinary specialization in industry and commerce, and, at least before the World War, in output of a few major products; with her deliberate sacrifice of agriculture, and the urban massing of population, she has exaggerated the features which are largely characteristic of the economy of Western Europe to a point far beyond that which other countries have reached or attempted to reach. From the specialization on a few industries there is, as has been observed, a reaction in most European countries, and in eastern and central Europe an attempt has been made to check the drift towards the towns by dividing the large landed estates into smaller holdings. But this revolution in agriculture has been accompanied by a deliberate policy of industrialization. The east, up to the Russian frontier, looks to and imitates the west, and in doing so breaks the unity and spreads the uniformity of Europe. It breaks the unity because with the industrialization of the agricultural countries the surplus of bread corn available for the rest of the continent is likely to be diminished and the demand for the manufactures of the north and west weakened. New or higher barriers obstructing the free flow of goods are constructed, the markets within Europe are restricted and the opportunities for large scale production reduced. But Europe is necessarily dependent on other continents and on warmer climates for many of her raw materials, and these she can only buy with what she herself produces. To buy cheaply she must produce cheaply, to produce cheaply she must be permitted to devote her energies free from artificial impediments to the manufacture or the cultivation of those goods for which the natural conditions or the quality of her workers best fit her.

The New, Post-war Barriers.—The war and its settlement increased the impediments to the exchange of goods and inevitably upset the balance and distribution of productive forces within Europe. Almost 11,000 kilometres of new frontiers were traced and along every kilometre was built a new tariff wall, here high, there low, behind which national economic lakes stagnate. The political frontiers themselves, even when as in Holland surmounted only by the tiniest parapet, must to some extent check the free flow of the forces of production. Goods move more readily than capital, and capital incomparably more willingly than labour. Even had there been no new tariffs the new political demarcations scored across the face of Europe would inevitably have affected the existing economic equilibrium.

Industrial Europe has never known free trade and the equilibrium which existed in 1913 was determined largely by the political boundaries which then existed. The new frontiers determined at Versailles sometimes cut and sometimes joined the natural fields of wealth. Thus the Lorraine iron field, previously divided between France and Germany, was reunited, but the whole was separated from the Ruhr coke with which the eastern half had previously been supplied without hindrance, and many of the German blast furnaces were cut off from their supplies of ore. Upon the iron and steel of the Lorraine, Luxemburg and the Saar, the iron works of Westphalia, and the engineering and shipbuilding industries throughout Germany had largely relied. Similarly, the division of Upper Silesia separated the blast furnaces of the Polish half from the hard coke for which they had been constructed, and many of the industries of eastern Germany from their supplies of coal, and severed or half severed, innumerable meshes of the net-work of lead, zinc and coal mines, furnaces and factories which had been gradually perfected during the last fifty years.

The new frontier cut through both the existing economic organism and the natural supplies of wealth which lay in the subsoil; but by the Treaty of 1922 between Germany and Poland time was allowed for the regrowth and training of that organism before the separation of the two parts was made complete.

The cotton mills of Lodz and Narva lost their Russian market; the engineering shops of Riga and Tallin and the dairy farms of the surrounding country were cut off from Petrograd.

Industrial Czechoslovakia could no longer readily dispose of her goods in her old markets in Austria, Hungary, Galicia, Transylvania and the southern littoral of the old Austro-Hungarian Empire: the spinning mills of Austria were divorced from the looms of Bohemia, the Styrian iron ore from the Moravian coke, the flour mills of Budapest from the corn lands of Transylvania and Croatia. The road between Central Europe and the Mediterranean at Fiume and Trieste has been obstructed; Bulgaria has been cut off from contact with the Aegean at Dedeagatch.

European Trade Frustration.—All these modifications of national boundaries have checked the growth of old economic organisms and caused a loss to vested interests. All large modifications of frontier must have this result. The frontiers which existed in 1913 could claim no very special economic virtue.

Transylvania is the natural complement to the old kingdom of Rumania; Posen, Congress Poland and Galicia were disintegrated by the treaties of the eighteenth and the legislation of the nineteenth century, not by natural forces. Of permanent significance as affecting the circulation of goods in Europe, the distribution of industry, and the growth of wealth is not the fact that frontiers have been changed, but that they have been increased in length, that they embrace more and smaller states, and that along their length higher protective tariffs have been constructed. Each new state has endeavoured to fabricate with the help of such tariffs those parts of the general mechanism of production of which it found itself deprived when its new frontiers were constituted, or to build up new industries for the employment of those who were temporarily thrown out of work. Thus have been forced into existence a new textile industry in Hungary, new engineering shops in Rumania, new motor-car factories in Czechoslovakia. Behind the quickset hedges planted at Versailles have been built formidable walls from which now a coping stone, now a whole line of bricks may occasionally be removed by way of reciprocal concession. The centre and south-east of Europe has thus been divided into allotments, and the agricultural produce of Russia is crushed painfully through a few state-guarded gates on a closed frontier stretching from north to south across the whole breadth of Europe. So the natural interchange of goods between east and west, or between the industrial and agricultural areas of the centre of Europe is impeded. But the new obstructions are not confined to the new frontiers. The highest tariffs in Europe are those of Spain; Britain has ceased to be a free-trade country.

Europe must export manufactured products to feed herself. Supplies of grain from Russia are reduced and controlled and from the rest of eastern Europe greatly curtailed. But it is on industrial products that her new and higher duties are imposed. The cost of production to the European agriculturist is thus raised and the possibility of cultivating poorer land reduced. The cost of living, the costs of production and the price at which manufactured articles can be sold in exchange for the raw materials and foodstuffs of other regions of the world are all enhanced. The power of Europe to compete is weakened by every denial of her essential unity and by every obstruction to her liberty of internal intercourse.

From century to century the political scene has changed; now this nation, now that, has occupied the forefront of the stage. But what Europe as a whole has had to offer has changed but little. Some of her minor gifts have been exhausted, part of her major legacies expended; one generation has chosen this source of wealth, another that, tin or copper or iron or coal. With the growth of science, unknown wealth has been discovered and old forms put to new uses. Timber to-day is converted more into pulp for paper than into charcoal for crucible steel; the platinum of the Urals, the uranium ore of Czechoslovakia, the bauxite deposits of Jugoslavia have lain awaiting the knowledge to employ them. Some other mines may have been worked out, but to the natural gifts has been added a vast accumulation of capital built up through centuries, and the essential heritage of Europe, her soil, her climate, her central position and great mineral wealth, still remain. (A. Lov.)

EUROPEAN CORN BORER (*Pyrausta nubilalis*), a pyralid moth of the subfamily Pyraustinae accidentally introduced into the United States from Europe and now considered to be a great potential pest to the principal agricultural crop of the States, namely Indian corn (*Zea Mays*). The species has a wide geographic range in the northern hemisphere, occurs all over Europe as far north as 58°. It occurs also in many parts of Asia, and in Pacific islands as far south as Guam and the Philippines. Its climatic range shows a variation from the dry steppes of south-eastern Russia to the moist tropical conditions of Guam. It is known in Europe as an enemy of maize, hops, millet and hemp, and has many other food plants. It was probably introduced into the United States in broom corn coming from Hungary, having been discovered in 1917 near Boston, Mass., in 1919 near Schenectady, N.Y., and in the same year near Buffalo, N.Y. There seems to have been an independent introduction in Ontario. The insect spread rapidly, and is now found in Maine, New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, Pennsylvania, Ohio, Indiana and Michigan. In Massachusetts it has many food plants, known under the popular names pigweed, smartweed, cocklebur, barnyard-grass, lambsquarters, ox-tail, and panic-grass. West of Pennsylvania it is largely confined to the maize plant. There are two generations each year in New England, but only one in its western range.

The female moth measures about an inch from tip to tip of the spread wings. The colour is variable, and ranges from pale yellow to light brown, the wings being marked by zigzag lines. The insect hibernates as a full grown larva in its burrow in the corn plant. In May or early June it transforms to a pupa within the stalk, remaining in this stage from ten days to two weeks. The moths issue, through holes previously cut by the larvae, in late June. They are active fliers, and lay their eggs in flat, irregular masses on the underside of the corn leaves, sometimes, however, on the upper sides, sometimes on the stalk or on the husk of the ears. Each moth lays an average of 400 eggs. The eggs hatch in four to nine days. The larvae feed for a few days on the surface of the leaf, but soon enter the stem of the plant. In the midwestern States they become nearly full-grown by the middle of August, but remain within their tunnels throughout the winter. In New England the moths issue in June; their larvae become fully grown toward the end of July, and the moths from the second brood issue during August and early September. Their eggs hatch, and the larvae enter the stalks, becoming full-grown before the appearance of cold weather.

Efforts at Control.—Extraordinary efforts have been made by the Federal Government and by the States to retard the spread of this injurious insect, at first by quarantines enforced by the inspection and seizure of all products likely to carry the borers, but it has been impossible to prevent the spread by the flight of the moths; and by the winter of 1926–27 midwestern farmers and stock-growers became so alarmed at the prospective damage that Congress was induced to pass an appropriation of $10,000,000 to be spent in an effort to stop further spread in a radical manner; in other words, to enforce along the border of spread the destruction during the winter months of all portions of the plant remaining in the fields. This effort was carried on with the co-operation of the States concerned during the late spring of 1927, and there can be no doubt that the result has been to retard the spread of the pest to a certain extent and to educate the corn planters of that part of the United States concerning the best methods of control. The corn borer becomes a serious pest only where cornstalks are allowed to stand in the field through the winter. During seven months of the year the full-grown larva remains in the lower part of the stalk. The mere pulling of the stalks and placing them in piles, as is done in certain parts of southeastern Europe, does not prevent the issuing of many moths in the spring; the absolute destruction of the stalks and their contents is necessary. A method of corn culture has grown up in the larger part of the United States which is peculiarly favourable to the increase and spread of this pest, and a reform in this method, which seems simple, will prevent the enormous damage that has been feared. The experts of the Federal Government, aided by especial funds appropriated by Congress, have made extensive investigations of this insect since its discovery in Massachusetts and New York, in the effort to find control measures. Some of these investigators have been stationed in Europe and have made careful studies of European methods and conditions. These experts have especially investigated the question of natural control and have sent to the United States many thousands of specimens of European parasites of the borer which have been multiplied in the United States and liberated in the fields.

See the publications of the U.S. Department of Agriculture, particularly *Farmers' Bulletin No. 1535*, and the publications of the State agricultural colleges and experiment stations. (L. O. H.)

EUROPEAN WAR, 1914–18: *see* WORLD WAR.

EUROPIUM is a very rare metallic element (symbol Eu, atomic number 63, atomic weight 152·0) belonging to the rare-earth group, discovered in 1896 by Demarçay. Previously, in

1889, Crookes noticed a band in the spectrum of some earths from samarskite and to the substance giving this spectrum he provisionally gave the name S. This was found, later, to be identical with europium. It was first obtained in a pure state by G. Urbain and H. Lacomb in 1904 by the employment of a very ingenious method which involved the crystallization of the double magnesium nitrates of the rare earths along with the isomorphous bismuth magnesium nitrate. The latter possessed a solubility similar to that of the europium salt and thus, by increasing the bulk of material, made the process easier to carry out. Owing to the great rarity of this metal, it is best obtained from the crude mixture of samarium and gadolinium oxides derived from monazite. The salts possess a pale pink colour and show a faint absorption spectrum. The spark spectrum of this element is very brilliant. (*See* RARE EARTHS.) (C. J.)

EURYDICE, in Greek mythology, the wife of Orpheus (q.v.).

EURYMEDON, one of the Athenian generals during the Peloponnesian War. In 428 B.C. he was sent by the Athenians to intercept the Peloponnesian fleet which was on the way to attack Corcyra, but was anticipated by Nicostratus with a squadron from Naupactus. In the following summer, in joint command of the land forces, he ravaged the district of Tanagra; and in 425 he was appointed, with Sophocles, the son of Sostratides, to the command of an expedition destined for Sicily. Having touched at Corcyra on the way, in order to assist the democratic party against the oligarchical exiles, Eurymedon proceeded to Sicily. He agreed to terms of peace proposed by Hermocrates, but the Athenians repudiated the agreement and fined him. In 414 Eurymedon, who had been sent with Demosthenes to reinforce the Athenians at the siege of Syracuse, was defeated and slain before reaching land (Thucydides iii., iv., vii.; Diod. Sic. xiii. 8, 11, 13).

EUSDEN, LAURENCE (1688–1730), English poet, son of the Rev. Laurence Eusden, rector of Spofforth, Yorkshire, was baptized on Sept. 6, 1688. He was educated at St. Peter's, York, and at Trinity college, Cambridge, of which he became a fellow. He was made poet laureate in 1718, and became rector of Coningsby, Lincolnshire, where he died on Sept. 27, 1730. His name is remembered by the numerous satirical allusions of Pope, *e.g.*,

> "Know, Eusden thirsts no more for sack or praise;
> He sleeps among the dull of ancient days."
> *Dunciad*, bk. i. 11. 293–294.

EUSEBIUS, a name borne by many bishops and others in the early Church. The most important are:

EUSEBIUS, bishop of Vercelli (d. 371), a strong opponent of Arianism, was with St. Augustine, the first Western bishop to unite with his clergy in adopting a strict monastic life after the Eastern model (*see* Ambrose, *Ep. 63 ad Vercellenses*, s. 66). The legend that he was stoned to death by the Arians was probably invented. His three extant letters are in Migne *Patrol. Lat.* vol. 12.

EUSEBIUS, bishop of Samosata (d. 380), is first mentioned among the Homoean and Homoeusian bishops who in 363 accepted the Homousian formula at the synod of Antioch presided over by Meletius, whose views he seems to have adopted (*see* MELETIUS OF ANTIOCH). According to Theodoret (5, 4, 8) he was killed at Doliche in Syria, by a stone cast by an Arian woman. He thus became a martyr, and found a place in the Catholic calendar (*see* the article by Loofs in Herzog-Hauck, *Realencykl.*, ed. 1898, v., p. 620).

EUSEBIUS OF LAODICEA, was an Alexandrian by birth, and gained so great a reputation for his self-denial and charity that when in 262 the city was besieged by the emperor Gallienus he obtained permission to lead out the non-combatants. In Syria, he took part in the controversy against Paul of Samosata, bishop of Antioch. He became bishop of Laodicea, probably in 263, and died before 268. (*See* the article by E. Hennecke in Herzog-Hauck, v. 619.)

EUSEBIUS, bishop of Rome for four months under the emperor Maxentius, in 309 or 310. The Christians in Rome, divided on the question of the reconciliation of apostates, on which Eusebius held the milder view, brought forward a competitor, Heraclius. Both competitors were expelled by the emperor. Eusebius was buried in St. Calixtus, at Rome. The epitaph, in eight hexameter lines, set up by his successor Damascus, contains all the available information.

EUSEBIUS (OF NICOMEDIA) (d. 341?), Greek bishop and theologian, was the defender of Arius more avowedly than his namesake of Caesarea, and from him the Eusebian or middle party specially derived its name, giving him in return the epithet of Great. His first bishopric was Berytus (Beirut) in Phoenicia, but his name is especially identified with the see of Nicomedia. He wrote a letter in defence of Arius to Paulinus, bishop of Tyre, which is preserved in the *Church History* of Theodoret. He appears to have been agreed with Eusebius of Caesarea in placing Christ above all created beings, the only begotten of the Father, but in refusing to recognize him to be "of the same substance" with the Father, who is alone in essence and absolute being.

At the council of Nicaea Eusebius of Nicomedia earnestly opposed the insertion of the Homousian clause and refused to sign the anathema directed against the Arians, "because he doubted whether Arius really held what the anathema imputed to him" (Sozom. ii. 15). After the council his zeal against the Athanasians led to his temporary banishment from his see but through the influence of the emperor's sister Constantia he was promoted to the see of Nicomedia, and by her favour he was later restored to his position. He was promoted in 339 to the see of Constantinople and became the leader of the anti-Nicene party till his death (*c.* 341). (*See* ARIUS.)

EUSEBIUS OF CAESAREA (Eusebius Pamphili) (*c.* 260–*c.* 340) (bishop of Caesarea in Palestine), ecclesiastical historian, was born probably in Palestine and died as bishop of Caesarea. In early youth he became acquainted with Pamphilus, presbyter of the Church of Caesarea, and founder of a theological school there (see *Hist. Eccl.* vii. 32). He assisted him in the preparation of an apology for Origen's teaching (*Hist. Eccl.* vi. 33), the first book of which survives in the Latin of Rufinus (printed in Routh's *Reliquiae sacrae*, iv. 339 *sq.*, and in Lommatzsch's edition of Origen's Works, xxiv. p. 293 *sq.*). After the death of his friend Eusebius withdrew to Tyre, and later, while the Diocletian persecution was still raging, to Egypt, where he seems to have been imprisoned, but soon released. He became bishop of Caesarea between 313 and 315, and in 331 declined the patriarchate of Antioch. Eusebius was one of the most learned men of his age, and stood high in favour with the emperor Constantine. At the council of Nicaea (325) he led the large middle party of Moderates, and submitted the first draft of the creed afterwards adopted with important changes. Later, he yielded to the Alexandrian party, and voted for a creed which repudiated the Arian position, with which he had previously sympathized. He seems to have discovered during the council that the Alexandrians were right in claiming that Arius was carrying his subordinationism so far as to deny all real divinity to Christ. His explanation of his conduct in a letter to the Caesarean church is exceedingly interesting (*see* Socrates, *Hist. Eccl.* 1, 8). With the extreme views of the Athanasian party, however, he was never in complete sympathy for they seemed to savour of Sabellianism, which always remained his chief dread.

Eusebius's greatness rests upon his vast erudition and his sound judgment. He is best known by his *History of the Christian Church* completed in 324 or early in 325. It is the most important ecclesiastical history of ancient times, and is written in the belief that the old order of things was passing away and with the apologetic purpose of exhibiting the history of Christianity as a proof of its divine origin and efficacy.

The value of the work does not lie in its literary merit, but in the wealth of the materials which it furnishes for a knowledge of the early church. Many prominent figures of the first three centuries are known to us only from its pages. Many fragments, priceless on account of the light which they shed upon movements of far-reaching consequence, have been preserved in it alone. Eusebius sometimes misinterprets his documents and misunderstands men and movements; but usually he presents us with the material upon which to form our own judgment. His *Chronicle* (*c.* 303; later continued down to 325), contains an epitome of universal history, and chronological tables exhibiting in parallel columns the royal succession in different nations, and accom-

panied by notes marking the dates of historical events. A revised edition of the second half with a continuation down to his own day was published in Latin by St. Jerome. His *Martyrs of Palestine* is an account of martyrdoms occurring in Palestine during the years 303 to 310, of most of which Eusebius himself was an eyewitness. The *Life of Constantine* is a panegyric rather than a sober history, but contains much valuable material. Eusebius's apologetic works include the *Contra Hieroclem, Praeparatio evangelica, Demonstratio evangelica* and *Theophania*. The first is a reply to a lost work against the Christians written by Hierocles, a Roman governor and contemporary of Eusebius. The second and third are important apologetic works of the early church. The former, in fifteen books, valuable for its numerous quotations from classical literature, contends that the Christians are justified in accepting the sacred writings of the Hebrews, and in rejecting the religion and philosophy of the Greeks. The latter, in twenty books, of which only the first ten and fragments of the fifteenth are extant, endeavours to prove from the Hebrew Scriptures that the Christians are right in going beyond the Jews and adopting new principles and practices. The *Theophania,* whose subject is the manifestation of God in the incarnation of the Word, aims to give with an apologetic purpose a brief exposition of the Divine authority and influence of Christianity. Of Eusebius' dogmatic and polemic writings, we have the *Contra Marcellum* and the *De theologia ecclesiastica*. The former exposes the errors of Marcellus (bishop of Ancyra), whom Eusebius accuses of Sabellianism, the latter refutes them. We also have parts of a General Introduction (Ἡ καθόλου στοιχειώδης εἰσαγωγή), which consisted of ten books (the sixth to the ninth books and a few other fragments still extant), under the title of *Prophetical Extracts*. It contains prophetical passages from the Old Testament relating to the person and work of Christ, accompanied by explanatory notes. Of Biblical and exegetical works we have a considerable part of Eusebius' Commentaries on the Psalms and on Isaiah, which are monuments of learning, and critical acumen, though marred by the use of the allegorical method characteristic of the school of Origen; also the *Onomasticon*, a work on the place names of Scripture; and an epitome and some fragments of a work in two parts on Gospel Questions and Solutions, the first part dealing with the genealogies of Christ given in Matthew and Luke, the second with the apparent discrepancies between the various gospel accounts of the resurrection. For other important works *see* Harnack, *Alt-christliche Literaturgeschichte*.

BIBLIOGRAPHY.—Eusebius' works were published in *Patrol. graeca*, tom. xix.–xxiv. and more critically in the Berlin Academy's *Die griechischen christlichen Schriftsteller der ersten drei Jahrhunderte*, 7 vols., Leipzig, 1912–14. Many have been published separately. Of the many editions of the *Church History*, the chief are: Heinichen's second edition, 3 vols., 1868–70, containing also the *Life of Constantine* and the *Oration in Praise of Constantine;* that by Burton (1838; a reprint in one vol. by Bright, 1881) and that by Kirsopp Lake with an Eng. trans. in Loeb Series (1926). The history was early put into Syriac (ed. by Bedjan, Leipzig, 1897; also by Wright, McLean and Merx, London, 1898), Armenian (ed. by Djarian, Venice, 1877), and Latin. English versions include that of McGiffert, in the *Nicene and Post-Nicene Fathers,* second series, vol i. (New York, 1890) and that of H. J. Lawlor who also translated in the same vol. *The Martyrs of Palestine* (1927). The *Chronicle*, was edited by Schoene 2 vols. (Berlin, 1866–75) and by Siegfried and Gelzer (1884). Gaisford published the *Prophetical Extracts* (Oxford, 1842), the *Praeparatio evangelica* (1843), the *Demonstratio evangelica* (1852), and the works against Hierocles and Marcellus (1852). The Greek text and an Eng. trans. of the *Contra Hieroclem* by F. C. Conybeare were published in the Loeb series (1912). An Eng. trans. of the *Proof of the Gospel* has been issued by W. J. Ferrar, 2 vols. (1920). The *Onomasticon* has been published frequently, among others by Lagarde (Göttingen, 2nd ed., 1887). The *Theophania* was first published by Lee (Syriac version, 1842; Eng. trans., 1843). The *Life of Constantine* and the *Oration in Praise of Constantine* were translated in the same vol. of the *Nicene Fathers* as the *Church History*. Biographical material for Eusebius is contained in Athanasius, Philostorgius, Socrates, Sozomen, Theodoret, Jerome's *De vir. ill.*, and Photius. *See* Stein, *Eusebius Bischof von Caesarea* (Würzburg, 1859); Lightfoot in the *Dictionary of Christian Biography;* the account by McGiffert in his translation of the *Church History;* Herzog-Hauck, *Realencyklop.;* Bardenhewer's *Patrologie;* and Mansi: *Concilia* xiii.

EUSEBIUS (OF MYNDUS), Greek Neoplatonist and pupil of Aedesius, who lived in the time of Julian. Criticizing the magical and theurgic side of Neoplatonism, he devoted himself principally to logic. Stobaeus in the *Sermones* collected a number of ethical dicta of one Eusebius, who may be identical with the Neoplatonist.

The fragments exist in Mullach's *Fragmenta Phil. Graec.*, and in Orelli's *Opuscula veter. graec. sentent. et mor.*

EUSEBIUS (OF EMESA) (d. *c.* 360), a learned ecclesiastic of the Greek church, was born at Edessa. After studying at Caesarea, Antioch and Alexandria he was offered in 339 the see of Alexandria in succession to the deposed Athanasius, but he declined. He accepted the small bishopric of Emesa (the modern Homs) in Phoenicia, but his scientific bent led his flock to accuse him of sorcery, and he had to flee to Laodicea. A reconciliation was effected, but Eusebius finally resigned his charge and lived a studious life in Antioch. His life was written by his friend George of Laodicea. The fragments of his numerous writings are in Migne, *Patrol. Graec.* vol. lxxxvi.

EUSKIRCHEN, a town of Germany, in the Prussian Rhine province, on a plateau lying to the east of the Eifel range, at the junction of railways from Cologne and Bonn and 10 m. W. of the latter. Pop. (1925) 14,549. Its industries include cloth, sugar and stocking manufactures, besides breweries, metal-ware factories and iron foundries.

EUSTACE, the name of four counts of Boulogne.

EUSTACE I., a son of Count Baldwin II., held the county from 1046 until his death in 1049.

His son, EUSTACE II. (d. 1093), count of Boulogne, was the husband of Goda, daughter of the English king Aethelred the Unready, and aunt of Edward the Confessor. Eustace paid a visit to England in 1051, and was honourably received at the Confessor's court. A brawl in which he and his servants became involved with the citizens of Dover led to a serious quarrel between the king and Earl Godwin. The latter, to whose jurisdiction the men of Dover were subject, refused to punish them. His contumacy was made the excuse for the outlawry of himself and his family. In 1066 Eustace came to England with Duke William, and fought at the battle of Hastings. In the following year, probably because he was dissatisfied with his share of the spoil, he assisted the Kentishmen in an attempt to seize Dover Castle. The conspiracy failed, and Eustace was sentenced to forfeit his English fiefs. Subsequently he was reconciled to the Conqueror, who restored a part of the confiscated lands.

Eustace died in 1093, and was succeeded by his son, EUSTACE III., who went on crusade in 1096, and died about 1125. On his death the county of Boulogne came to his daughter, Matilda, and her husband Stephen, count of Blois, afterwards king of England, and in 1150 it was given to their son, Eustace IV.

EUSTACE IV. (d. 1153) became the heir-apparent to his father's possessions by the death of an elder brother before 1135. In 1137 he did homage for Normandy to Louis VII. of France, whose sister, Constance, he subsequently married. Eustace was knighted in 1147, and in 1151 joined Louis in an abortive raid upon Normandy, which had accepted the title of the empress Matilda, and was now defended by her husband, Geoffrey of Anjou. At a council held in London on April 6, 1152 Stephen induced a small number of barons to do homage to Eustace as their future king; but the primate, Theobald, and the other bishops declined to perform the coronation ceremony on the ground that the Roman curia had declared against the claim of Eustace, whose death in 1153 opened up the possibility of a peaceful settlement between Stephen and his rival, the young Henry of Anjou.

See Sir James Ramsay, *Foundations of England,* vol. ii. (1898); J. M. Lappenberg, *History of England under the Norman Kings* (trans. B. Thorpe, 1857); and Freeman's *Hist. of the Norman Conquest* (1867–79).

EUSTATHIUS (d. *c.* 1193), archbishop of Thessalonica, Byzantine scholar and author (probably a native of Constantinople), was bishop of Myra in Lycia, before being transferred to Thessalonica in 1175. He opposed the emperor Manuel, when the latter desired an alteration in the formula of abjuration necessary for converts from Mohammedanism, and in 1185, when Thessalonica was captured by William II. of Sicily, secured

religious toleration for the conquered. His best known work is his *Commentary on the Iliad and Odyssey of Homer*, which contains valuable extracts from the scholia of other critics, whose works are lost. The commentary on the geographical epic of Dionysius Periegetes also preserves much of Stephanus of Byzantium and the lost writings of Arrian. Of his commentary on Pindar only the preface, which contains an essay on lyric poetry, a life of Pindar and an account of the Olympic games, remains. Eustathius also wrote a history of the conquest of Thessalonica by the Normans, and *The Reform of Monastic Life*.

Editions: Homer Commentary, by G. Stallbaum (1825–30); preface to Pindar Commentary, by F. W. Schneidewin (1837); Dionysius Commentary in C. W. Müller, *Geographici Graeci minores*, ii.; pentecostal hymn, in A. Mai, *Spicilegium Romanum*, v. 2 (1841). The smaller works and the *De Thessalonica* were edited (1832 and 1839) by L. F. Tafel; many will be found in Migne, *Patrol. Graeca*, cxxxv., cxxxvi. Five new speeches have been edited by W. Regel, *Fontes rerum Byzantinarum*, i. (1892). *See* J. E. Kalitsunakis, *Mittel- und Neugriechische Erklärungen bei Eustathius* (1919).

EUSTATHIUS, of Antioch, sometimes styled "the Great" (*fl.* 325), was a native of Side in Pamphylia. He was bishop of Beroea (*c.* 320), and patriarch of Antioch before the Council of Nicaea (325). In that assembly he ably opposed the Arians, though the *Allocutio ad Imperatorem* with which he has been credited is hardly genuine. His anti-Arian polemic against Eusebius of Caesarea made him unpopular among his fellow-bishops in the East, and a synod convened at Antioch in 330 passed a sentence of deposition, which was confirmed by the emperor. He was banished to Trajanopolis in Thrace, where he died, probably *c.* 337, though possibly not till 360.

Eustathius's works are in Migne's *Patrol. Graec.* vol. 18. His *Engastrimytho contra Origenem* was edited by A. Jahn in *Texte und Untersuchungen*, ii. 4. *See* H. E. Burn, *S. Eustathius of Antioch* (1926), R. V. Sellers, *Eustathius of Antioch* (Cambridge, 1928), and Loofs's article in Herzog-Hauck's *Realencyklopädie*.

EUSTATHIUS or **EUMATHIUS,** surnamed Macrembolites ("living near the long bazaar"), the last of the Greek romance writers, flourished in the second half of the 12th century A.D. His title *Protonobilissimus* shows him to have been a person of distinction, and if he is also correctly described in the mss. as chief keeper of the ecclesiastical archives, he must have been a Christian. He was the author of *The Story of Hysmine and Hysminias*, in 11 books, a tedious and inferior imitation of the *Cleitophon and Leucippe* of Achilles Tatius. There is nothing original in the plot, and the work is tasteless and often coarse. The digressions on works of art, apparently the result of personal observation, are the best part of the work. A collection of 11 *Riddles*, of which solutions were written by the grammarian Manuel Holobolos, is also attributed to Eustathius.

The best edition of both romance and riddles is by I. Hilberg (1876, who fixes the date of Eustathius between 850 and 988), with critical apparatus and prolegomena, including the solutions; of the *Riddles* alone by M. Treu (1893). On Eustathius generally, *see* J. C. Dunlop, *History of Fiction* (1888, new ed. in Bohn's *Standard Library*); K. Krumbacher, *Geschichte der byzantinischen Litteratur* (1897); E. Rohde, *Der griechische Roman* (1900). There are many translations in modern languages, of which that by P. le Bas (1825) may be recommended; there is an English version from the French by L. H. le Moine (London and Paris, 1788).

EUSTYLE, an architectural term for the intercolumnation (*q.v.*) in which the distance between the adjacent columns is two and a half times the lower diameter of the column. The Greek word (εὔστυλος) signifies well columned, and is applied because this intercolumnation was considered, in general, the best (Vitruvius, III., 3).

EUTAW SPRINGS (Battle of). The last battle fought in the field in the Southern States during the American Revolutionary War. This action took place on Sept. 8, 1781, in the vicinity of Eutawville, a small village (pop. 1920, 285) in Orangeburg county, S.C., about 55m. N.N.W. of Charleston. The village lies on high ground near the Santee river, in a region abounding in swamps, limestone cliffs and pine forests. The neighbouring Eutaw springs issue first from the foot of a hill and form a large stream of clear, cool water, but this, only a few yards away, again rushes underground to reappear about ½m. farther on. Near these springs about 2,300 Americans, under Gen. Nathaniel Greene, attacked a slightly inferior force under Col. Alexander Stewart; at first the Americans drove the British before them, but later in the day the latter took a position in a brick house and behind palisades, and from this position the Americans were unable to drive them. On the night of the 9th, however, Col. Stewart retreated toward Charleston, abandoning 1,000 stand of arms. The battle has been classed as a tactical victory for the British and a strategical victory for the Americans, terminating a campaign which left Gen. Greene in virtual possession of the Carolinas, the British thereafter confining themselves to Charleston. The Americans lost in killed and wounded 408 men (including Col. William Washington, wounded and captured); the British, 693.

EUTECTIC MIXTURE, of two substances, that mixture which has the lowest freezing point and is further distinguished by the fact that its two components crystallize out simultaneously in the proportions in which they were present in the liquid. (*See* Alloys: *Cooling Curves;* and Chemistry: *Physical: Boiling-Point* and *Freezing-Point Curves*.)

EUTHYDEMUS, a native of Magnesia, who overturned the dynasty of Diodotus of Bactria, and became king of Bactria about 230 B.C. (Polyb. xi. 34; Strabo xi. 515 wrongly makes him the first king). In 208 he was attacked by Antiochus the Great, whom he tried in vain to resist on the shores of the river Arius, the modern Herirud (Polyb. x. 49). The war lasted three years, and was on the whole fortunate for Antiochus. But he saw that he was not able to subdue Bactria and Sogdiana, and so in 206 concluded a peace with Euthydemus, through the mediation of his son Demetrius, in which he recognized him as king (Polyb. xi. 34). Soon afterwards Demetrius (*q.v.*) began the conquest of India. There exist many coins of Euthydemus; those on which he is called god are struck by the later king Agathocles. Other coins with the name Euthydemus, which show a youthful face, are presumably those of Euthydemus II., who cannot have ruled long and was probably a son of Demetrius. (Ed. M.)

EUTIN, a town of Germany, belonging to Oldenburg, situated on the Lake Eutin, 20 m. N. from Lübeck by the railway to Kiel. Pop. 6,884. Eutin was, according to tradition, founded by Count Adolf II. of Holstein. In 1155 it fell to the bishopric of Lübeck, and after many changes during the middle ages and the Thirty Years' War, it came into the possession of the house of Holstein, and hence to Prussia in 1866. It possesses a palace with a fine park. In the neighbourhood is a beautiful tract of country, rich in beech forests and fjords, known as "the Holstein Switzerland," largely frequented in summer by the Hamburgers. Furniture and paper are manufactured here.

EUTROPIUS, Roman historian. He held the office of secretary (*magister memoriae*) at Constantinople, accompanied Julian on his expedition against the Persians (363), and was alive during the reign of Valens (364–378), to whom he dedicates his history. This work (*Breviarium historiae Romanae*) is a compendium, in ten books, of Roman history from the foundation of the city to the accession of Valens. It was compiled from the best accessible authorities, and is generally impartial. As the Latin is clear and simple the work was for a long time a favourite school-book. Its independent value is small, but it sometimes fills a gap left by the more authoritative records. The *Breviarium* was enlarged and continued by Paulus Diaconus (*q.v.*); and by Landolfus Sagax (*c.* 1000).

Of the Greek translations by Capito Lycius and Paeanius, the version of the latter is extant in an almost complete state. The best edition of Eutropius is by H. Droysen (1879), containing the Greek version and the enlarged editions of Paulus Diaconus and Landolfus; smaller critical editions C. Wagener (1884), F. Rühl (1887). J. Sorn's *Der Sprachgebrauch des Historikers Eutropius* (1892) contains a systematic account of the grammar and style of the author. There are numerous English school editions and translations.

EUTYCHES (*c.* 380–*c.* 456), a presbyter and archimandrite at Constantinople, first came into notice at the council of Ephesus (431), where, as a zealous adherent of Cyril (*q.v.*) of Alexandria, he vehemently opposed the doctrine of the Nestorians (*q.v.*), and affirmed that after the union of the two natures, the human and the divine, Christ had only *one nature*, that of the incarnate Word, and that therefore His human body was essentially differ-

ent from other human bodies. In this he went beyond Cyril and the Alexandrine school generally, who took care to guard against circumscribing the true humanity of Christ. It would seem, however, that Eutyches differed from the Alexandrine school chiefly in word, for equally with them he denied that Christ's human nature was transmuted into his divine nature. His imprudent assertions led to his being accused of heresy by Domnus of Antioch and Eusebius, bishop of Dorylaeum, at a synod at Constantinople in 448 which excommunicated him; at a council held in Ephesus (449) he was reinstated in his office, and Eusebius, Domnus and Flavian, his chief opponents, were deposed, the Alexandrine doctrine of the "one nature" receiving the sanction of the church. In Oct. 451, a council (the fourth oecumenical) which met at Chalcedon (*q.v.*) declared the Ephesus synod to have been a "robber synod," its proceedings were annulled, and, in accordance with the rule of Leo, Bishop of Rome, it was declared that the two natures were united in Christ without any alteration or absorption. Eutyches died in exile, but of his later life nothing is known. In the 6th century a monk, Jacob, who united the separated divisions of the Eutychians, or Monophysites (*q.v.*), into one church, now known as the Jacobite Church of Armenia, Egypt and Ethiopia, propagated his doctrines of Eutyches.

See Mansi, *Sacr. Conc. Collectio* vi.–vii.; R. L. Ottley, *The Doctrine of the Incarnation,* ii.; A. Harnack, *Hist. of Dogma,* iv. *passim;* F. Loofs, *Dogmengeschichte* (4th ed., 1906), and the art. in Herzog-Hauck, *Realencyk.*

EUTYCHIANUS, pope from 275 to 283. His original epitaph was discovered in the catacombs (*see* Kraus, *Roma sotterranea,* p. 154 *sqq.*), but nothing more is known of him.

EUTYCHIDES, of Sicyon, Greek sculptor of the latter part of the 4th century B.C., was a pupil of Lysippus. His most noted work was a statue of "Fortune," which he made for the city of Antioch (founded 300 B.C.). The goddess, who embodied the idea of the city, was represented seated on a rock, with the river Orontes at her feet. Copies of this group have been identified in a statue in the Vatican and in several bronze and silver statuettes in various museums. The composition also occurs on Syrian coins of Tigranes (83 B.C.). Most statues of cities since erected borrow something from this work of Eutychides.

EUYUK or **EYUK** (the *eu* pronounced as in French), a small village in Asia Minor, in the Angora vilayet, 12 m. N.N.E. of Boghaz Keui (*Pteria*), built on a mound which contains some remarkable ruins of a large building—a palace or sanctuary—anterior to the Greek period and belonging to the same civilization as the ruins and rock-reliefs at Pteria. These ruins consist of a gateway and an approach enclosed by two lateral walls, 15 ft. long, from the outer end of which two walls return outwards at right angles, one to right and one to left. The gateway is flanked by two huge blocks, each carved in front into the shape of a sphinx, while on the inner face is a relief of a two-headed eagle with wings displayed. Of the approach and its returning walls only the lower courses remain: they consist of large blocks adorned with a series of bas-reliefs similar in type to those carved on the rocks of Boghaz Keui. Behind the gateway is another vestibule leading to another portal which gives entrance to the building, the lateral walls and abutments of the portal being also decorated with reliefs much worn. These reliefs belong to that pre-Greek oriental art generally called Hittite, of which there are numerous remains in the eastern half of the peninsula. They represent scenes in the ritual of the indigenous naturalistic religion which was spread, in slightly varying forms, all over Asia Minor, and consisted in the worship of the self-reproductive powers of nature, personified in the great mother-goddess (called by various names Cybele, Leto, Artemis, etc.) and the god her husband-and-son (Attis, Men, Sabazios, etc.), representing the two elements of the ultimate divine nature (*see* GREAT MOTHER OF THE GODS). Here, as in the oriental mysteries generally, the goddess is made more prominent. Where Greek influence affects the native religion, emphasis tends to be laid on the god, but the character of the religion remains everywhere ultimately the same (*see* Ramsay, *Cities and Bishoprics of Phrygia,* ch. iii.).

EVAGORAS, son of Nicocles, king of Salamis in Cyprus, 410–374 B.C. He claimed descent from Teucer, half-brother of Ajax, son of Telamon, and his family had long been rulers of Salamis until supplanted by a Phoenician exile. He regained the throne in 410. According to Isocrates, whose panegyric must however be read with caution, Evagoras was a model ruler, whose aim was to promote the welfare of his state and of his subjects by the cultivation of Greek refinement and civilization, which had been almost obliterated in Salamis by a long period of barbarian rule. He cultivated the friendship of the Athenians, and after the defeat of Conon at Aegospotami (405 B.C.) he afforded him refuge and hospitality. For a time he also maintained friendly relations with Persia, and secured the aid of Artaxerxes II. for Athens against Sparta. He took part in the battle of Cnidus (394), in which the Spartan fleet was defeated, and for this service his statue was placed by the Athenians side by side with that of Conon in the Ceramicus. But the energy and enterprise of Evagoras soon roused the jealousy of the Great King, and relations between them became strained. From 391 they were virtually at war. Aided by the Athenians and the Egyptian Hakor (Acoris), Evagoras extended his rule over the greater part of Cyprus, crossed over to Asia Minor, took several cities in Phoenicia, and persuaded the Cilicians to revolt. After the peace of Antalcidas (387), to which he refused to agree, the Athenians withdrew their support, since by its terms they recognized the lordship of Persia over Cyprus. For ten years Evagoras carried on hostilities single-handed, except for occasional aid from Egypt. At last he was totally defeated at Citium, and compelled to flee to Salamis. Here, although closely blockaded, he managed to hold his ground, and took advantage of a quarrel between the Persian generals to conclude peace (376). Evagoras was allowed to remain nominally king of Salamis, but in reality a vassal of Persia, to which he was to pay a yearly tribute. The chronology of the last part of his reign is uncertain. In 374 he was assassinated by a eunuch from motives of private revenge.

The chief authority for the life of Evagoras is the panegyric of Isocrates addressed to his son Nicocles; *see* also Diod. Sic. xiv. 115, xv. 2–9; Xenophon, *Hellenica,* iv. 8; W. Judeich, *Kleinasiatische Studien* (Marburg, 1892).

EVAGRIUS (*c.* 536–600), surnamed SCHOLASTICUS, Church historian, was born at Epiphania in Coele-Syria. His surname shows him to have been an advocate, and it is supposed that he practised at Antioch. He was the legal adviser of Gregory, patriarch of that city, whom he successfully defended at Constantinople against certain serious charges. This brought him to the notice of the emperor Tiberius Constantine, who honoured him with the rank of quaestorian; Maurice Tiberius made him master of the rolls. Evagrius's name has been preserved by his *Ecclesiastical History* in six books, extending over the period from the third general council (that of Ephesus, 431) to the year 593. It thus continues the work of Eusebius, Socrates, Sozomen and Theodoret. Though credulous and not wholly trustworthy, it is on the whole impartial, and appears to have been compiled from original documents, from which many valuable excerpts are given. It is particularly valuable for the history of dogma during the 5th and 6th centuries. Evagrius made use of the writings of Eustathius, John of Epiphania, John Malalas, Procopius, and (possibly) Menander Protector.

The best edition of the History is that of L. Parmentier and J. Bidez (London, 1898), which contains the Scholia; it is also included in Migne's *Patrologia Graeca,* lxxxvi. There is an English translation in Bohn's *Ecclesiastical Library. See* Krumbacher, *Geschichte der byzantinischen Litteratur* (1897); F. C. Baur, *Die Epochen der kirchlichen Geschichtsschreibung* (1852); L. Jeep, *Quellenuntersuchungen zu den griechischen kirchenhistoriken* (1884).

EVANDER (Gr Εὔανδρος), represented in a late and artificial legend as an Arcadian who settled very early on the Palatine, at Rome, where he founded a town named Pallantion, after his native place. He also had a son Pallas. He instituted the Lupercalia (q.v.), in imitation of the Arcadian Lycaa, and introduced

some of the blessings of civilization, including writing. He hospitably received Hercules (*see* HERCULES) and Aeneas (q.v.). His mother was the goddess Carmentis or Carmenta. His father was Hermes. The one bit of reality in all this is the name of Carmentis (Carmenta); the rest is bad etymologies of *Palatinus* and *Lupercalia;* perhaps *Euandros* is intended to mean "strong-man," in allusion to the name Roma, identified with Gr. ῥώμη, "strength."

See Schwegler, *Römische Geschichte,* I. 350 *et seq.;* Roscher's *Lexikon,* s.v.

EVANGELICAL ALLIANCE, an association of individual Christians of different denominations formed in London in Aug. 1846, at a conference of over 900 clergymen and laymen from all parts of the world, and representing upwards of 50 sections of the Protestant Church. The idea originated in Scotland in the preceding year, and was intended "to associate and concentrate the strength of an enlightened Protestantism against the encroachments of popery and Puseyism, and to promote the interests of a scriptural Christianity," as well as to combat religious indifference. The object of the alliance, according to a resolution of the first conference, is "to enable Christians to realize in themselves and to exhibit to others that a living and everlasting union binds all true believers together in the fellowship of the Church." At the same conference the following nine points were adopted as the basis of the alliance: "Evangelical views in regard to the divine inspiration, authority and sufficiency of the Holy Scriptures; the right and duty of private judgment in the interpretation of the Holy Scriptures; the unity of the Godhead and the Trinity of persons therein; the utter depravity of human nature in consequence of the Fall; the incarnation of the Son of God, His work of atonement for sinners of mankind, and His mediatorial intercession and reign; the justification of the sinner by faith alone; the work of the Holy Spirit in the conversion and sanctification of the sinner; the immortality of the soul, the resurrection of the body, the judgment of the world by our Lord Jesus Christ, with the eternal blessedness of the righteous and the eternal punishment of the wicked; the divine institution of the Christian ministry, and the obligations and perpetuity of the ordinances of Baptism and the Lord's Supper," it being understood, however, (1) that such a summary "is not to be regarded in any formal or ecclesiastical sense as a creed or confession," and (2) that "the selection of certain tenets, with the omission of others, is not to be held as implying that the former constitute the whole body of important truth, or that the latter are unimportant." The general conferences have been occupied with the discussion of the "best methods of counteracting infidelity, Romanism and ritualism, and the desecration of the Lord's Day," and of furthering the positive objects of the alliance. The latter are sometimes stated as follows: (*a*) "the world girdled by prayer," a world-wide week of prayer being advocated; (*b*) "the maintenance of religious liberty throughout the world"; (*c*) "the relief of persecuted Christians in all parts"; (*d*) "the manifestation of the unity of all believers and the upholding of the evangelical faith."

See D. S. Schaff, article "Evangelical Alliance" in Hastings, *Encyclopaedia of Religion and Ethics;* A. J. Arnold, *History of the Evangelical Alliance* (1897); the *Annual Reports* of the British and American branches; the *Proceedings* of the various General Conferences, especially the jubilee in London (1896); and the monthly journal *Evangelical Christendom.*

EVANGELICAL CHURCH, a religious body formerly known as the Evangelical Association, founded in America at the beginning of the 19th century by Jacob Albright (1759–1808), a German Pennsylvanian, born and reared in the Lutheran Church. Converted in 1791, he began to preach the Gospel to his German-speaking compatriots in 1796 and organized classes in 1800. The new body adopted in general the Wesleyan standards of doctrine, and in a somewhat more democratic form the polity of the M.E. Church. Albright was elected bishop in 1807 and died in 1808. The first General Conference was held in 1816. The General Conference, a delegated body composed of an equal number of ministerial and lay members representing the annual conferences, is the supreme administrative, legislative and judicial body in the church and meets quadrennially. In the quadrennium between 1887 and 1891 a division took place resulting from internal controversies. The majority section continued to function as the Evangelical Association, the name adopted in 1816, and the other as the United Evangelical Church, until in 1922, at a joint General Conference in Detroit, Mich., the two bodies reunited under the name the Evangelical Church. This church (1928) has a total membership of 252,000, 2,300 ministers and 2,600 churches. It is divided into 30 annual conferences, 24 in the United States, 2 in Canada, 3 in Europe and 1 in Japan. It has important missions in China and Africa. There are two publishing houses in America, one in Harrisburg, Pa., and one in Cleveland, O. There are in the United States three colleges, two seminaries, two orphan homes, six homes for the aged and ten hospitals. In Europe it has 32,000 members, chiefly in Germany, France, Switzerland, Poland and Latvia, 2 publishing houses, 1 seminary, 4 old peoples' homes, 15 hospitals and 600 deaconess-nurses. There are seven bishops, one of whom resides in Europe. (S. P. S.)

EVANGELICAL SYNOD OF NORTH AMERICA, a Protestant church dating from Oct. 1840, and known, in its early years, as the German Evangelical Church Association of the West. It was formed under the leadership of missionaries from the mission institutes of Basle and Barmen who were engaged in pioneer work in Missouri and Illinois. The original organization was strengthened in 1858 by amalgamation with the German Evangelical Church Association of Ohio, and later by the inclusion of the German United Evangelical Synod of the East (1860), the Evangelical Synod of the North-West (1872) and the United Evangelical Synod of the East (1872). The church bases its position on the Bible as interpreted by the symbols of the Lutheran and Reformed churches so far as they are in agreement, points of difference being left to "that liberty of conscience which prevails in the Evangelical Church." The church, which has 1,197 ministers and 350,000 communicant members, is divided into districts, with officers responsible to the General Synod, which meets every four years. There are boards for home and foreign missions, the latter operating chiefly in the Central Provinces of India and in Honduras, C.A. The literature of the church is in German and English, chiefly the latter.

EVANGELICAL UNION, a religious denomination which originated in the suspension of the Rev. James Morison (1816–1893), minister of a United Secession congregation in Kilmarnock, Scotland, for certain views regarding faith, the work of the Holy Spirit in salvation, and the extent of the atonement, which were regarded by the supreme court of his Church as anti-Calvinistic and heretical. Morison was suspended by the presbytery in 1841 and thereupon definitely withdrew from the Secession Church. His father, who was minister at Bathgate, and two other ministers, being deposed not long afterwards for similar opinions, the four met at Kilmarnock on May 16, 1843 (two days before the "Disruption" of the Free Church), and, on the basis of certain doctrinal principles, formed themselves into an association under the name of the Evangelical Union, "for the purpose of countenancing, counselling and otherwise aiding one another, and also for the purpose of training up spiritual and devoted young men to carry forward the work and 'pleasure of the Lord.'" The doctrinal views of the new denomination gradually assumed a more decidedly anti-Calvinistic form, and they began also to find many sympathizers among the Congregationalists of Scotland. At last, in 1896, after prolonged negotiation, the Evangelical Union was incorporated with the Congregational Union of Scotland.

See *The Evangelical Union Annual; History of the Evangelical Union,* by F. Ferguson (Glasgow, 1876); *The Worthies of the E.U.* (1883); W. Adamson, *Life of Dr. James Morison* (1898).

EVANGELISM: *see* REVIVALS, RELIGIOUS.

EVANS, SIR ARTHUR JOHN (1851–), British archaeologist, was born at Nash Mills, Herts, July 8, 1851, the eldest son of Sir John Evans, K.C.B. (*q.v.*). Educated at Harrow, Brasenose college, Oxford, and Göttingen, he was elected fellow of Brasenose and was keeper of the Ashmolean museum at Oxford from 1884 till 1908. He travelled in Finland and Lapland in 1873–74, and from 1875 onwards studied archaeological and ethnological conditions in the Balkan States. In 1882 he was arrested by the Austrians on a charge of complicity in insurrection in Dal-

matia. In 1893 he began his investigations in Crete, which have resulted in discoveries of the utmost importance concerning the early history of Greece and the eastern Mediterranean. An account of his discovery of the pre-Phoenician script and of the excavation of the palace of Knossos is given *s.v.* (*See* ARCHAEOLOGY; CRETE.) In 1911 he was knighted. Evans held academic honours from learned societies in many European countries. He presided over the British Association in 1916 and 1919.

His chief publications are: *Cretan Pictographs and Prae-Phoenician Script* (1896); *Further Discoveries of Cretan and Aegean Script* (1898); *The Mycenaean Tree and Pillar Cult* (1901); *Scripta Minoa* (1909); *Palace of Minos I.* (2 vols., 1921, 1928); and reports on the excavations at Knossos. He also edited and supplemented E. A. Freeman's *History of Sicily*, vol. iv. (1891).

EVANS, SIR GEORGE DE LACY (1787–1870), British soldier, was born at Moig, Limerick, in 1787, and educated at Woolwich academy. He entered the army in 1806 as a volunteer, and saw service in India, in the Peninsular War, and in America. He returned to England in 1815 and took part in the Waterloo campaign as assistant quartermaster-general on Sir T. Picton's staff. He went on half-pay in 1818. He was M.P. for Rye from 1830 to 1832, and for Westminster from 1833 to 1865, except for a short interval from 1841–46. In 1835 he commanded the Spanish Legion in the Carlist War, on the side of the queen of Spain. In 1854, as lieutenant-general he commanded the 2nd Division of the Army of the East in the Crimean War, where he was wounded at the battle of the Alma and on Oct. 26 defeated a large Russian force. Pennefather took his command when he was absent on account of illness, and on his return Evans declined to take back the command, but aided Pennefather with his advice in the struggle. He was invalided home in Feb. 1855. In 1861 Evans, who had received the G.C.B., was promoted full general. He died in London on Jan. 9, 1870.

EVANS, GEORGE ESSEX (1863–1909), Australian poet, was born in London on June 18, 1863. He was educated at Haverford West grammar school, and Guernsey, and in 1881 went to Australia. In 1882 his poems began to appear in the *Queenslander* under the pseudonym of "Christophus," and he afterwards contributed to other Australian papers, *The Brisbane Courier*, the *Sydney Bulletin*, and others. In 1888 he was appointed district registrar at Toowoomba. He edited, in 1892, 1893 and 1897 an unsuccessful literary annual, *The Antipodean*, and was also employed to write reports for the Queensland Government. He founded the Toowoomba Austral Association in 1903, and wrote several commemorative odes. His poetry reflects his enthusiasm for Australian life and for the country. He died at Toowoomba on Nov. 11, 1909.

His works include *The Repentance of Magdalene Despard, and other Verses* (1891), *Loraine, and other Verses* (Melbourne, 1898); *The Sword of Pain* (Toowoomba, 1905), *The Secret Key, and other Verses* (Sydney, 1906); and *Queen of the North* (*The Times*, Aug. 7, 1909), celebrating the 50th anniversary of Queensland.

EVANS, SIR JOHN (1823–1908), English archaeologist and geologist, son of the Rev. Dr. A. B. Evans, head master of Market Bosworth grammar school, was born at Britwell Court, Bucks, on Nov. 17, 1823. He was the author of three books, standard in their respective departments: *The Coins of the Ancient Britons* (1864, repr. 1890); *The Ancient Stone Implements, Weapons and Ornaments of Great Britain* (1872, 2nd ed. 1897); and *The Ancient Bronze Implements, Weapons and Ornaments of Great Britain and Ireland* (1881). He took a leading part in the affairs of various learned societies, was president of the Numismatic Society (1872–1908) and treasurer of the Royal Society (1878–98). As president of the Society of Antiquaries he was *ex officio* a trustee of the British Museum, and subsequently he became a permanent trustee. He was created K.C.B. in 1892. He died at Berkhamsted on May 31, 1908.

EVANS, OLIVER (1755–1819), American mechanician, was born at Newport (Del.), in 1755. He was apprenticed to a wheelwright, and at the age of 22 he invented a machine for making the card-teeth used in carding wool and cotton. In 1780 he became a partner with his brothers, who were practical millers, and soon introduced various labour-saving appliances which both cheapened and improved the processes of flour-milling. Turning his attention to the steam engine, he employed steam at a relatively high pressure. The plans of his invention were sent over to England in 1787 and it is said were seen by R. Trevithick. Evans made use of his engine for driving mill machinery; and in 1803 constructed a steam-dredging machine, which also propelled itself on land. He died in New York on April 16, 1819.

EVANSTON, a beautiful residential city of Cook county, Ill., U.S.A., on Lake Michigan, adjoining Chicago on the north. It is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific, and the Chicago, North Shore and Milwaukee railways. The population was 37,234 in 1920, of whom 6,771 were foreign-born white and 2,522 were negroes, and was estimated locally at over 63,000 in 1928. Manufactures, though relatively unimportant, are increasing and in 1925 the output amounted to $13,647,674. The assessed valuation of property subject to taxation (not including the large exempt holdings of educational institutions) was $28,480,060 in 1926. The city grew up around Northwestern university (Methodist Episcopal; incorporated 1851) which in 1855 was located on the lake shore 12m. N. of the heart of Chicago. The campus now covers 75ac.; the enrolment (including the departments in Chicago) is about 10,-000; the endowment is over $14,000,000; the Dyche stadium, on the 12ac. athletic field, accommodates 45,000 spectators. The professional schools of medicine, law and dentistry are in Chicago. Evanston is also the seat of three Methodist Episcopal theological schools: the Garrett Biblical institute (1855), the Norwegian-Danish Theological seminary (1870) and the Wesley academy and Theological seminary (organized in Galesburg in 1870); and of the National Kindergarten and Elementary college, founded in Chicago in 1886. It was the home of Frances E. Willard, and the publishing offices of the National Woman's Christian Temperance Union are here. It was chartered as a town in 1863; as a city in 1892. The population had reached 19,259 in 1900 and was almost doubled in the next 20 years. Territory has been annexed from time to time, until the area of the city is 7·57 sq. miles.

EVANSVILLE, a city of south-western Indiana, U.S.A., on the Ohio river, 200m. (by the river, though only 75m. in a beeline) below Louisville; a port of entry and the county seat of Vanderburg county. It is on Federal highway 41, and is served by river steamers and by the Big Four, the Chicago and Eastern Illinois, the Evansville and Ohio Valley, the Evansville Suburban and Newburgh, the Illinois Central, the Louisville and Nashville, the Louisville, Henderson and St. Louis and the Southern railways. The population was 85,264 in 1920 (89% native white), and was estimated by the Census Bureau at 96,600 in 1927.

The city occupies 9·5 sq.m. of land around a sharp bend of the river, partly low and partly hilly and rugged. It is the seat of the Southern Indiana hospital for the insane, a United States Marine hospital, and Evansville college (Methodist), which was chartered in 1919 to succeed a college founded in 1856 at Moores Hill, Ind. The assessed valuation of property in 1927 was $132,856,810. The surrounding country is a rich agricultural and coal-producing region. There are two coal mines within the city limits and 150 within a radius of 50 miles. Because of this environment and its exceptional transportation facilities by land and by water, Evansville is the principal distributing point and manufacturing centre of southern Indiana. It is one of the leading hardwood lumber markets of the country and has an extensive shipping business in corn, wheat, pork and tobacco. The output of its factories in 1925 was valued at $67,467,886. Among the principal manufactures are auto trucks, auto bodies, electric and gas refrigerators, steam shovels, gas engines, agricultural implements, tools, electric headlights, glass bottles, infant foods, grain products, brick and furniture. Bank debits in 1926 amounted to $492,327,000. A city-plan commission was created under the permissive State legislation of 1921. Evansville was settled about 1812; laid out in 1817 and named after Robert Morgan Evans (1783–1844), one of the founders, who was an officer in the War of 1812. It soon became a thriving commercial town, with a large river trade; was incorporated in 1819 and chartered as a city in 1847. In 1850 its population was 3,235. The completion in 1853 of the Wabash and Erie canal from Evansville to Toledo (400m.) gave it a great

stimulus, and by 1860 the population had grown to 11,484. In the next 20 years it increased 155%; between 1880 and 1900, over 100%; and between 1900 and 1920, 44%.

EVAPORATION, in the chemical industry, consists in converting a liquid into a vapour in order to remove it from solids dissolved in it. While in some instances this can be done in open kettles, it is customary to use closed units called *evaporators,* which may be single, duplex, triple or quadruple in assembly. When so grouped, they are known as "effects." Thus, a "triple effect" evaporator is common in the sugar industry, being used to concentrate syrup by the removal of water. Evaporators enable work to be done under partial vacuum, which both increases the quantity of water that can be eliminated per pound of fuel used and also permits lower temperatures to be employed, the latter being important in handling some types of material. By maintaining a higher vacuum on each succeeding effect, the hot vapours from the preceding may be used to assist in heating the next effect in the series. Evaporators are of many types as to material employed in construction, means for increasing circulation of the liquid being evaporated and means for discharging crystals drawn out of solution. The size is also variable, one of the largest in operation being some 30 ft. in diameter.

Some evaporators are continuous and others operate on the batch system. The "sugar pan" of the refinery, a single, large evaporator, is usually of the batch type, and in it the "sugar boiler" manipulates syrups of various concentrations to produce crystals of the desired size in the final stages of concentrating sugar from syrups of various origins.

EVARISTUS, fourth pope (*c.* 98–105), was the immediate successor of Clement.

EVARTS, WILLIAM MAXWELL (1818–1901), American lawyer, was born in Boston (Mass.), Feb. 6, 1818. He graduated from Yale in 1837, attended Harvard Law school in 1839, was admitted to the bar in New York in 1841, and soon took high rank in his profession. In 1860 he was chairman of the New York delegation to the Republican national convention. He was chief counsel for President Johnson during the impeachment trial, and from July 1868 until March 1869 he was attorney-general of the United States. In 1872 he was counsel for the United States in the "Alabama" arbitration. During President Hayes' administration (1877–81) he was secretary of State; and from 1885 to 1891 he was one of the senators from New York. He died in New York on Feb. 28, 1901.

EVE is the name given in the early Yahwist narratives of the Creation and the Fall to the wife of the first man (Heb. *ḥawwah,* meaning uncertain = life, clan, or snake). The story goes that Yahweh, finding his man dissatisfied with the merely vegetable world in whose midst he lived, determined to create a suitable companion for him. His first attempt was made along the lines which had produced the man; *i.e.,* he modelled clay into various shapes, brought them to life, and introduced them to the man. At the sight of each creature as it came before him, the man uttered an exclamation, which became the creature's name, but the exclamations showed that none of the experiments was successful in providing what the man most needed. Another method was then adopted. Throwing the man into a hypnotic and anaesthetic slumber, Yahweh took from him a rib (carefully mending again the spot whence it was taken) and built this into a woman. The man's exclamation on seeing her proved the success of the method, and the narrator adds a comment explaining that this event is the origin of marriage (Gen. ii. 18–24). In Gen. iii. it is the woman who is more exposed than the man to the wiles of the serpent, and she falls into sin, dragging her husband with her. Her punishment lies in sexual attractions and subjection, and in the pains of childbirth. After the notice of the birth of her children (Gen. iv. 1, 2, 25) there is no further allusion to Eve in the Old Testament.

In post-biblical Jewish literature Eve is not infrequently mentioned. There is a reference in the Book of Tobit (viii. 6, 7), and there are new details in the Book of Jubilees (ch. iii.), while the Targum of Jonathan and Philo both add to the story. In the New Testament the comment in Gen. ii. 24 is cited as illustrating the true nature of marriage, and there are references in 2 Cor. xi. 3 and 1 Tim. ii. 13. In Christian theology the narratives are used chiefly in connection with the doctrines of Man and of Sin. (*See* ADAM.)

EVECTION (Latin for "carrying away"), in astronomy, the largest inequality produced by the action of the sun in the monthly revolution of the moon around the earth. The deviation expressed by it has a maximum amount of about 1° 15′ in either direction. It was discovered by Hipparchus about 150 B.C.

EVELETH, a city of St. Louis county, Minnesota, U.S.A., 61m. N.N.W. of Duluth; served by the Duluth and Iron Range and the Duluth, Missabe and Northern railways. The population was 7,205 in 1920 (37% foreign-born white) and was estimated locally at 9,000 in 1928. It is one of the iron-mining cities of the Mesabi range, which here makes a great bend, so that there are deposits south, south-west, west and north-west of the city. It has fine public schools, and a community recreation building with dance-hall and seating space for 4,000, a kitchen and dining-room, and a curling rink. Iron ore was discovered here in Oct. 1892, by David T. Adams, and the first shipment (5,600 tons) was made about two years later. Total shipments to 1927 amounted to 87,954,165 tons. In the early years underground mining prevailed. Later the open-pit system was extensively used, and over 42,000,000cu.yd. of material have been removed in stripping operations; but with the exhaustion of deposits near the surface the trend again turned to underground shafts. Eveleth was laid out in 1893, and was named after Erwin Eveleth, who visited the site in 1885, while exploring the timber resources of the region. In 1899–1900 practically the entire village was moved, as the original site was found to be underlain with ore. The first mine office, a log-house, has been preserved. The city was incorporated in 1902.

EVELYN, JOHN (1620–1706), English diarist, was born at Wotton House, near Dorking, Surrey, the younger son of Richard Evelyn, a large landowner. When John Evelyn was five years old he went to live with his mother's parents at Cliffe, near Lewes. He refused to leave his "too indulgent" grandmother for Eton, and when on her husband's death she married again, the boy went with her to Southover, where he attended the free school of the place. He was admitted to the Middle Temple in Feb. 1637, and in May he became a fellow commoner of Balliol college, Oxford. He left the university without taking a degree, and in 1640 was residing in the Middle Temple. In that year his father died, and in July 1641 he crossed to Holland. He was enrolled as a volunteer in Apsley's company, then encamped before Genep on the Waal, but his commission was apparently complimentary, his military experience being limited to six days of camp life, during which, however, he took his turn at "trailing a pike." He returned in the autumn to find England on the verge of civil war. Evelyn's part in the conflict is best told in his own words:—

> 12th November was the battle of Brentford, surprisingly fought. . . . I came in with my horse and arms just at the retreat; but was not permitted to stay longer than the 15th by reason of the army marching to Gloucester; which would have left both me and my brothers exposed to ruin, without any advantage to his Majesty . . . and on the 10th [December] returned to Wotton, nobody knowing of my having been in his Majesty's army.

At Wotton he employed himself in improving his brother's property, making a fishpond, an island and other alterations in the gardens. But he found it difficult to avoid taking a side; he was importuned to sign the Covenant, and obtained leave from the king in Oct. 1643 to travel abroad. From this date his *Diary* becomes full and interesting. He travelled in France and visited the cities of Italy, returning in the autumn of 1646 to Paris, where he became intimate with Sir Richard Browne, the English resident at the court of France. In June of the following year he married Browne's daughter and heiress, Mary, then a child of not more than 12 years of age. Leaving his wife in the care of her parents, he returned to England to settle his affairs. He visited Charles I. at Hampton Court in 1647, and during the next two years maintained a cipher correspondence with his father-in-law in the royal interest. In 1649 he obtained a pass to return to Paris, but in 1650 paid a short visit to England. The defeat of Charles II. at Worcester in 1651 convinced him that the royalist cause was

hopeless, and he decided to return to England. He went in 1652 to Sayes Court at Deptford, a house which Sir Richard Browne had held on a lease from the Crown. This had been seized by the parliament, but Evelyn was able to compound with the occupiers for £3,500, and after the Restoration his possession was secured. Here his wife joined him, their eldest son, Richard, being born in Aug. 1652. Under the Commonwealth Evelyn amused himself with his favourite occupation of gardening, and made many friends among the scientific inquirers of the time. He was one of the promoters of the scheme for the Royal Society, and in the king's charter in 1662 was nominated a member of its directing council. Evelyn was secretary of the Society in 1672, and as an enthusiastic promoter of its interests was twice (in 1682 and 1691) offered the presidency. Through his influence Henry Howard, duke of Norfolk, was induced to present the Arundel marbles to the University of Oxford (1667) and the valuable Arundel library to Gresham college (1678).

Meanwhile he had refused employment from the Government of the Commonwealth, and had maintained a cipher correspondence with Charles. In 1659 he published an *Apology for the Royal Party*, and in December of that year he vainly tried to persuade Colonel Herbert Morley, then lieutenant of the Tower, to forestall General Monk by declaring for the king. From the Restoration onwards Evelyn enjoyed unbroken court favour till his death in 1706; but he never held any important political office, although he filled many minor posts. He was commissioner for improving the streets and buildings of London, for examining into the affairs of charitable foundations, commissioner of the Mint, and of foreign plantations. In 1664 he accepted the responsibility for the care of the sick and wounded and the prisoners in the Dutch war. He stuck to his post throughout the plague year, contenting himself with sending his family away to Wotton. He found it impossible to secure sufficient money for the proper discharge of his functions, and in 1688 he was still petitioning for payment of his accounts in this business. In the reign of James II., during the earl of Clarendon's absence in Ireland, he acted as one of the commissioners of the privy seal. He was seriously alarmed by the king's attacks on the English Church, and refused on two occasions to license the illegal sale of Roman Catholic literature. He concurred in the revolution of 1688, in 1695 was entrusted with the office of treasurer of Greenwich hospital for old sailors, and laid the first stone of the new building on June 30, 1696. In 1694 he left Sayes Court to live at Wotton with his brother, whose heir he had become, and whom he actually succeeded in 1699. He spent the rest of his life there, dying on Feb. 27, 1706. Evelyn's house at Sayes Court had been let to Captain, afterwards Admiral John Benbow, who was not a "polite" tenant. He sublet it to Peter the Great, who was then visiting the dockyard at Deptford. The tsar did great damage to Evelyn's beautiful gardens, and, it is said, made it one of his amusements to ride in a wheelbarrow along a thick holly hedge planted especially by the owner. The house was subsequently used as a workhouse, and is now almshouses, the grounds having been converted into public gardens by Mr. Evelyn in 1886.

It will be seen that Evelyn's politics were not of the heroic order. But he was honourable and consistent in his adherence to the monarchical principle throughout his life. With the court of Charles II. he could have had no sympathy, his dignified domestic life and his serious attention to religion standing in the strongest contrast with the profligacy of the royal surroundings. But he made no enemies, and the king himself seems to have liked him. His *Diary* is therefore a valuable chronicle of contemporary events from the standpoint of a moderate politician and a devout adherent of the Church of England. He had none of Pepys's love of gossip, and was devoid of his all-embracing curiosity, as of his diverting frankness of self-revelation. Both were admirable civil servants, and they had a mutual admiration for each other's sterling qualities. Evelyn's *Diary* covers more than half a century (1640–1706) crowded with remarkable events, while Pepys only deals with a few years of Charles II.'s reign.

Evelyn was a generous art patron, and Grinling Gibbons was introduced by him to the notice of Charles II. His domestic affections were very strong. He had six sons, of whom John (1655–99), the author of some translations, alone reached manhood. He has left a pathetic account of the extraordinary accomplishments of his son Richard, who died before he was six years old, and of a daughter Mary, who lived to be 20 and probably wrote most of her father's *Mundus muliebris* (1690). Of his two other daughters, Susannah, who married William Draper of Addiscombe, Surrey, survived him.

Evelyn's *Diary* remained in ms. until 1818. It is in a quarto volume containing 700 pages, covering the years between 1641 and 1697, and is continued in a smaller book which brings the narrative down to within three weeks of its author's death. A selection from this was edited by William Bray, with the permission of the Evelyn family, in 1818, under the title of *Memoirs illustrative of the Life and Writings of John Evelyn, comprising his Diary from 1641 to 1705/6, and a Selection of his Familiar Letters*. Other editions followed, the most notable being those of Mr. H. B. Wheatley (1879) and Mr. Austin Dobson (3 vols., 1906). Evelyn's active mind produced many other works, and although these have been overshadowed by the famous *Diary* they are of considerable interest. They include: *Of Liberty and Servitude* . . . (1649), a translation from the French of François de la Mothe le Vayer, Evelyn's own copy of which contains a note that he was "like to be call'd in question by the Rebells for this booke"; *The State of France, as it stood in the IXth year of . . . Louis XIII.* (1652); *An Essay on the First Book of T. Lucretius Carus de Rerum Natura. Interpreted and made English verse by J. Evelyn* (1656); *The Golden Book of St. John Chrysostom, concerning the Education of Children. Translated out of the Greek by J. E.* (printed 1658, dated 1659); *The French Gardener: instructing how to cultivate all sorts of Fruit-trees* . . . (1658), translated from the French of N. de Bonnefons; *A Character of England* . . . (1659), describing the customs of the country as they would appear to a foreign observer, reprinted in *Somers' Tracts* (ed. Scott, 1812), and in the *Harleian Miscellany* (ed. Park, 1813); *The Late News from Brussels unmasked* . . . (1660), in answer to a libellous pamphlet on Charles I. by Marchmont Needham; *Fumifugium, or the inconvenience of the Aer and Smoak of London dissipated* (1661), in which he suggested that sweet-smelling trees should be planted in London to purify the air; *Instructions concerning erecting of a Library* . . . (1661), from the French of Gabriel Naudé; *Tyrannus or the Mode, in a Discourse of Sumptuary Laws* (1661); *Sculptura: or the History and Art of Chalcography and Engraving in Copper* . . . (1662); *Sylva, or a Discourse of Forest Trees . . . to which is annexed Pomona . . . Also Kalendarium Hortense* . . . (1664); *A Parallel of the Ancient Architecture with the Modern* . . . (1664), from the French of Roland Fréart; *The History of the three late famous Imposters, viz. Padre Ottomano, Mahomed Bei, and Sabatei Sevi* . . . (1669); *Navigation and Commerce . . . in which his Majesties title to the Dominion of the Sea is asserted against the Novel and later Pretenders* (1674), which is a preface to a projected history of the Dutch wars undertaken at the request of Charles II., but countermanded on the conclusion of peace; *A Philosophical Discourse of Earth* . . . (1676), a treatise on horticulture, better known by its later title of *Terra; The Compleat Gardener* . . . (1693), from the French of J. de la Quintinie; *Numismata* . . . (1697). Some of these were reprinted in *The Miscellaneous Writings of John Evelyn*, edited (1825) by William Upcott. Evelyn's friendship with Mary Blagge, afterwards Mrs. Godolphin, is recorded in the diary, when he says he designed "to consecrate her worthy life to posterity." This he effectually did in a little masterpiece of religious biography which remained in ms. in the possession of the Harcourt family until it was edited by Samuel Wilberforce, bishop of Oxford, as the *Life of Mrs. Godolphin* (1847), reprinted in the "King's Classics" (1904). The picture of Mistress Blagge's saintly life at court is heightened in interest when read in connexion with the scandalous memoirs of the comte de Gramont, or contemporary political satires on the court. Numerous other papers and letters of Evelyn on scientific subjects and matters of public interest are preserved, a collection of private and official letters and papers

(1642–1712) by, or addressed to, Sir Richard Browne and his son-in-law being in the British Museum (*Add. mss.* 15857 and 15858).

Next to the *Diary* Evelyn's most valuable work is *Sylva.* By the glass factories and iron furnaces the country was being rapidly depleted of wood, while no attempt was being made to replace the damage by planting. Evelyn put in a plea for afforestation, and besides producing a valuable work on arboriculture, he was able to assert in his preface to the king that he had really induced landowners to plant many millions of trees.

See *Handlist of works of John Evelyn and books connected with him* (1916) and, for his life, the introduction to Austin Dobson's edition of the *Diary* (1906); *Early Life and Education of John Evelyn* (Oxford Historical and Literary Studies, vol. 11, 1920).

EVERDINGEN, ALLART VAN (1621–?1675), Dutch painter and engraver, studied under Peter de Molyn at Haarlem and settled about 1657 at Amsterdam, where he remained till his death. Everdingen realized the large and effective system of coloured and powerfully shaded landscape which marks the precursors of Rembrandt. It is still an open question when de Molyn wielded influence on his clever disciple. We find Allart at first a painter of coast scenery. But on one of his expeditions he is said to have been cast ashore in Norway, and during the repairs of his ship he visited the inland valleys and thus gave a new course to his art. In early pieces he represents the sea in motion under varied, but mostly clouded, aspects of sky. Their general intonation is strong and brown and effects are rendered in a powerful key, but the execution is much more uniform than that of Jacob Ruysdael. A dark scud lowering on a rolling sea near the walls of Flushing characterizes Everdingen's "Mouth of the Schelde," in the Hermitage at Leningrad. Storm is the marked feature of sea-pieces in the Staedel or Robartes collections; and a strand with wreckers at the foot of a cliff, in the Munich Pinakothek, may be a reminiscence of personal adventure in Norway. But the Norwegian coast was studied in calms as well as in gales; and a fine canvas at Munich shows fishermen on a still and sunny day taking herrings to a smoking hut at the foot of a Norwegian crag. Everdingen was a precursor of Jacob Ruysdael in a certain form of landscape composition; but though very skilful in arrangement and clever in effects, Everdingen remains much more simple in execution; he is much less subtle in feeling or varied in touch than his great and incomparable countryman. Five of Everdingen's cascades are in the museum of Copenhagen alone; of these, one is dated 1647, another 1649. In the Hermitage at Leningrad is a fine example of 1647; another in the Pinakothek at Munich was finished in 1656. Of his etchings and drawings there are much larger and more numerous specimens in England than elsewhere. He died in Amsterdam and his collection of pictures was sold on March 11, 1676.

His two brothers, JAN and CAESAR, were both painters. CAESAR (1606–79) was mainly known as a portrait painter.

EVEREST, SIR GEORGE (1790–1866), British surveyor and geographer, was born at Gwerndale, Brecknockshire, on July 4, 1790, and educated at Marlow. He then went to Woolwich. He went to India as a cadet in 1806, and took part in the reconnaissance of Java (1814–16). From then to his retirement in 1843 he was employed on surveys in India. For the rest of his life he lived in England, was knighted in 1861, and died at Greenwich on Dec. 1, 1866. His geodetical work ranks among the finest of its kind; his measurement of the meridional arc of India, $11\frac{1}{2}°$ in length, is accounted as unrivalled in the records of the science. In great part the Indian survey is what he made it. Mount Everest is named after him.

EVEREST, MOUNT, the highest mountain in the world. It is a peak of the Himalayas situated in Nepal almost precisely on the intersection of the meridian 87 E. long. with the parallel 28 N. lat. Its elevation as at present determined by trigonometrical observation is approximately 29,140 ft. The peak has been called Everest after Sir George Everest (*q.v.*), who completed the trigonometrical survey of the Himalayas in 1841 and first fixed its position and altitude. *See* MOUNTAINEERING.

(X.)

ASCENT OF MOUNT EVEREST

A description of the attempts to climb Mt. Everest may be divided under three headings: the reconnaissance expedition of 1921; the first attempt, in 1922, and the second, in 1924.

Previous attempts had been made to obtain permission to travel in that part of Tibet and to explore and attempt to climb Mt. Everest, but only the expeditions of 1921, 1922, and 1924 are dealt with here. The extraordinary advance in the relations between Tibet and the outside world made it possible in 1920 to approach the Tibetan Government with every hope of success in obtaining from them permission to approach the mountain and explore its surroundings. As a preliminary, Col. Howard-Bury, in 1920, visited Phari Dzong. His negotiations were successful and in the winter of that year the first expedition was organized to reconnoitre and explore all the approaches to the great group and to make preliminary climbs on the mountain to ascertain the conditions and favourable points of attack.

THE RECONNAISSANCE EXPEDITION OF 1921

This preliminary expedition carried out its work in the most complete manner the following summer. Routes to Everest, through the district of Shekar and Kharta Sheka, were thoroughly explored and mapped. The approaches to Mt. Everest on all its northern faces were thoroughly examined. Relations were established with all the local authorities. This expedition was excellently constituted for the work in hand. Under the leadership of Lt.-Col. C. K. Howard-Bury, D.S.O., the climbing party consisted of C. H. Bullock, Dr. A. M. Kellas, G. L. Mallory, and Harold Raeburn. Maj. H. T. Morshead, D.S.O., and Maj. O. E. Wheeler, M.C., went as surveyors and Dr. A. M. Heron as geologist. A. F. R. Wollaston, D.S.C., was doctor, naturalist, and botanist. Among them was one mountaineer and scientist whose name stands out pre-eminently in the exploration of the Himalaya—Dr. Kellas, who, unfortunately, died during the march through Tibet.

The Rongbuk Valley.—The first object was to explore the Rongbuk valley beyond the Rongbuk monastery. From there the mountaineering party pushed up the west Rongbuk glacier, which descends directly from the northern faces of Mt. Everest, but failed to find the true approach to the mountain up the narrow mouth of the east Rongbuk glacier. This glacier was later on in the year surveyed by Wheeler and the true approach was established. Later, the expedition crossed over to the low-lying country to the east of Mt. Everest at Kharta Sheka.

From there a pass was found named the Lhakpa La, 22,000ft., which led to the head of the east Rongbuk glacier. From this point the mountaineering members of the party were able to trace the most likely line of attack on the mountain and actually mounted by difficult snow and ice slopes to a col on the main north ridge, descending from Everest, which they named the Chang La or North Col. By this time the season was late, the weather was breaking and no more work could be effected. The reconnaissance expedition had collected an immense amount of information and had mapped the country to the north of Everest.

THE ATTEMPT OF 1922

On the information and experience of the reconnaissance expedition the second expedition to Everest was organized, which was to complete the exploration of the group and to carry out the ascent of the great mountain. Brig.-Gen. the Hon. C. G. Bruce, C.B.,M.V.O., was in command, with Col. E. L. Strutt as second-in-command. The climbing party consisted of Mr. G. L. Mallory, Maj. E. F. Norton, D.S.O., R.A., Dr. T. H. Somervell, Dr. A. W. Wakefield, and Capt. G. I. Finch, who was oxygen officer to this party. Dr. T. G. Longstaff was doctor and naturalist. Mr. C. G. Crawford, I.C.S., Capt. J. G. Bruce, M.C., and Capt. C. J. Morris were the transport officers. Maj. H. T. Morshead, D.S.O., was surveyor, and Capt. J. B. L. Noel photographer.

Choice of Season.—It had been found necessary to make the attempt early in the year, as giving a better chance of good weather and of finding the snowy conditions on the mountain more favourable to an assault; but this early start also carried with it a great deal more exposure and fatigue on the journey

from Darjeeling to Everest; for on this route the passes cut off the southern Himalaya from the north and several high and exposed ridges have to be crossed. Naturally, too, the outfit was much greater, and for the first time in the exploration of the mountains experiments were to be made in the artificial administration of oxygen as an assistance in counteracting the effects of low atmospheric pressure. By the end of April 1922 the expedition was collected in the Rongbuk valley and the base camp established within two miles of the snout of the west Rongbuk glacier. A vast amount of stores of all descriptions had been transported to this spot, employing some 350 transport animals.

The Transport Problem.—It is necessary at this point to explain how great is the problem of attacking such a mountain as Everest. It differs from an ordinary mountaineering expedition in that many of the methods necessary for polar exploration must be put in force. A large number of first-class porters are required. For them special clothing and food are necessary, which greatly adds to the difficulties of supply. The expedition drew its porters mainly from subjects of Nepal, belonging to a tribe known as Sherpas. They are true Tibetans, who for many generations have settled on the southern slope of the Himalaya. They live in a steeper and slightly less elevated country than Tibet and are thoroughly suitable for the work; but among them there were also certain true Tibetans of Tibet. These men proved a great success through all the expeditions.

Importance of the Monsoon.—But the real problem is the race with the monsoon. The period from May 1 to early June is the only suitable time for the attack on the mountain, and even this is dominated by the approach of the monsoon. Up to the arrival of the south-west monsoon all the northern slopes of the Himalaya are swept by an intensely dry and cold wind. While these conditions continue the mountains are safe, if human beings can endure the terrible cold, fatigue and low atmospheric pressure. When once the humid and warm south-west monsoon is established the mountains are unapproachable, snows thaw, avalanches fall, and progress is made impossible. Hence great exertion has to be made in a short time.

Camps Established.—Up the east Rongbuk glacier camps were established from the base camp at 16,500ft. above sea-level to camp 3, three stages higher up, which was placed near the foot of the slopes leading to the Chang La or North Col. At camp 3 the advanced base of the expedition was established, at a height of 21,000ft., and here were accumulated stores of every description for the attack on the mountain. From here a high camp was successfully established in good weather on the North Col. From this camp the first attempt without the assistance of oxygen was made.

First Assault on the Mountain.—The four members of the party who were chosen for this effort, Norton, Somervell, Mallory and Morshead, set out from the North Col. With great difficulty they established a camp at about 25,000ft. on the sheltered side of the great north ridge which descends from Everest. This camp was carried up for them and pitched by the special Sherpa porters. It is worthy of note that until this expedition only once in the whole history of mountain exploration has a camp been pitched as high as 23,000ft., the height of the Chang La, and that was only for one night. The camp referred to was that of Meade's expedition on Kamet in Garhwal. This camp at 25,000ft. was occupied on May 19. The following morning three of the climbers, Somervell, Norton and Mallory, continued their attempt on Everest, Morshead having to be left behind as he was suffering from frost-bite and exhaustion. The climbing party pushed on under trying conditions of wind and weather until they attained the height of 26,985ft., the highest point reached by human beings up to that time. Here time and strength gave out, and a retreat was made. The descent was most toilsome, but finally the camp at 25,000ft. was reached, and Morshead, now worse, had to be conducted back from this point in bad weather to the North Col. In traversing back from the gite on the face of the mountain, an accident nearly occurred from a slip; but after a dramatic and exciting incident the laborious descent was continued, and finally, completely worn out, they reached the camp on the North Col at midnight. Everyone was more or less frost-bitten, Morshead severely.

First Attempt with Oxygen.—Later, on May 25, a second attempt was made by Finch and J. G. Bruce, using the oxygen apparatus from as low down as camp 3. They were accompanied by Naik Tejbir Bura, a young Gurkha non-commissioned officer who belonged to Capt. Bruce's regiment, the 6th Gurkha Rifles. This party followed in the footsteps of the previous one, camping, however, some 500ft. higher, at a height of 25,500ft. on the main ridge itself, their porters thus surpassing the efforts of the previous party. The porters returned to the North Col, but the climbing party were caught that night in a furious hurricane and were camp-bound for two nights and a day. The morning of the second day, the weather having calmed, they set out, using the full oxygen apparatus and employing the Gurkha non-commissioned officer to carry spare oxygen bottles. On reaching the height of 26,000ft. this young man could proceed no farther. The two mountaineers continued alone from this point and reached a height of some 27,300ft. Their return journey, still using oxygen and picking up reserve oxygen supplies on the way down, was in great contrast to the terrible experiences of the first party. They not only descended the mountain at good speed, but continued from the North Col or Chang La directly down to the advanced base at camp 3. The expedition then returned to the base camp for rest, all members of the party being greatly exhausted. From here certain members of the expedition, including Morshead, were too ill to stay on, and returned to India.

Third Assault.—A third attempt was organized, and the party left on June 3, consisting of Finch, Mallory, Somervell, Crawford, and Wakefield. Finch soon had to turn back and join the homing party. The remainder again camped at the advanced base, and on the morning of June 7, attempted to reach the North Col; but unfortunately they had been overtaken three days before by bad weather and heavy snow, and following the route formerly used to the North Col, they were obliged to traverse snow slopes rendered extremely dangerous by the accumulation of fresh snow. They were caught in a great avalanche, which swept down the face of the mountain side and carried down the whole of the party of 17, roped in groups of four and five. Two of these groups, one of four and one of five men, were swept over an ice cliff some 60ft. high, and only two out of the nine men thus carried away were saved. The leading rope consisting of three climbers, Crawford, Mallory and Somervell, was carried down for some 150ft. by the avalanche and stopped unharmed well above the danger point. This third attempt ended the expedition of 1922, which had added immensely to the knowledge of the possibilities of further acclimatization at high altitudes.

THE ATTEMPT OF 1924

The 1924 expedition consisted of Brig.-Gen. the Hon. C. G. Bruce, C.B., M.V.O., in command, and of Lt.-Col. E. F. Norton, D.S.O., R.A., second-in-command. The climbing party consisted of Capt. J. G. Bruce, M.C., Messrs. Bentley Beetham, J. de V. Hazard, A. C. Irvine, G. L. Mallory, N. E. Odell and Dr. T. H. Somervell. Mr. E. O. Shebbeare was transport officer, Maj. R. W. G. Hingston, M.C., I.M.S., doctor and naturalist, and Capt. J. B. L. Noel was again photographer. Leaving Darjeeling at about the same time as before, it arrived a few days earlier at the same base camp at Rongbuk. Its transport had been improved and increased. Unfortunately, during the march up, Gen. Bruce was obliged to return to India owing to illness.

Bad Weather at Base Camp.—On arrival at the base camp, every effort was made to establish a line of intermediate camps between the base camp and camp 3 with the greatest possible rapidity; but the expedition was overtaken by hurricane after hurricane during the month of May, at a time when fair weather is ordinarily to be expected. The temperatures experienced were very much lower than in 1922, and it was very soon discovered that a low temperature, high wind, hard work, and a low atmospheric pressure together are enough to wear out the very strongest constitution in a very short period. So for some three weeks the expedition struggled in a continuous battle to establish

not only the camps on the line of communication but also the alpine base on the summit of the North Col. This terrible fight against the elements, occasioning several returns for recuperation to the base camp, not only delayed the expedition very much indeed but reduced their strength and that reserve of power which is necessary for the final great assault—the great test of all; nor at high altitudes can that lost strength ever be adequately regained.

New Route to North Col.—The route that it was necessary to utilize between camp 3 at 21,000ft. and the North Col camp at 23,000ft. was far steeper and more difficult than that of 1922; but it had the advantage of being safe from the avalanches which render the easier slopes of the 1922 route most dangerous after such weather as was experienced in this season. But it was on this route that another accident almost occurred. After the new difficult route to the North Col had been forced by Norton, Hazard led the first party of porters and established the camp on May 22. On the following day, on his descent from the North Col camp to camp 3 in bad weather, it was discovered that four porters had remained actually on the North Col itself. A hurricane that night and the following day prevented communication with them, but on the day succeeding, Norton, Somervell and Mallory formed a rescue party to extricate these men from their dangerous position. This they successfully accomplished after a most dramatic incident, two of the porters, when crossing a dangerous face, slipping down and being brought up at the edge of an ice cliff. From this position they were rescued after heroic efforts. It was a most brilliant performance, but all members of the party were now terribly worn by exposure to wind and low temperatures, $-23°$ being registered even at camp 3. After this the expedition retired to the base camp for a complete rest.

The climbers and porters alike were completely worn out. Norton led them down to the monastery at the mouth of the Rongbuk valley, presided over by a remarkable Lama, a man in whom every Buddhist member of the party placed absolute faith. Here a service was held, the Lama blessed and encouraged the men, and then, when morale was re-established, Norton led the whole expedition back again to the advanced base camp 3. Hopes were now raised by the splendour of the weather. With reorganized plans, on June 1 camp 4 was re-established on a larger scale than ever, and from this camp the climbing party started the real assault on the mountain. There were few porters left who were fit to make such an immense effort as was required of them, and therefore several attempts were made by parties of two climbers, assisted by whatever porters were available. Mallory and J. G. Bruce pitched camp 5 at 25,000ft., but owing to the exhaustion of their porters were obliged to return.

They were followed on June 3 by Norton and Somervell, who, passing them, actually pitched a camp at 26,800ft. elevation, three men having been found fit enough to carry loads without the assistance of oxygen to this great height. From this point, with the greatest pain and trouble, Somervell and Norton reached a height on the following day of 28,200ft.; they again descended to the North Col. Somervell had been working under disadvantageous conditions, suffering terribly from a high altitude throat. So parched does one's throat become in this intensely cold and dry air that it forms more than an inconvenience, even a danger. Norton had been fit and well, but the following morning awoke suffering from snow blindness. An unforgettable episode occurred when, quite blind, he was taken down that steep and difficult descent by Hingston and Hazard.

The Last Attempt.—There was still one more attempt to be made by Mallory and Irvine. There had been defects in the oxygen apparatus and but little oxygen was available. They were assisted by a supporting party consisting of Odell and Hazard. On June 6 they left the 25,000ft. camp with three porters, who again carried loads for them to 27,000 feet. On June 8 they left camp 6 for their attempt. Odell on that morning arrived alone at this highest camp, to watch their progress and report on it, and to take such steps for their comfort as were considered necessary. He caught a glimpse of the climbers for a few moments high up on the mountainside; the mists blew across and he saw them no more. Returning to camp 4 he awaited their return; but on the following morning, seeing no sign of them, he searched the mountainside without effect. On June 10, for the third time, he mounted the slopes to the 27,000ft. camp—in itself an unprecedented effort—but could find no signs of Mallory and Irvine, and, communicating with Norton, evacuated the mountain.

Thus stood the battle with Everest up to 1928. Unfortunately, the expedition also lost one young Gurkha non-commissioned officer from over-exposure, and one Tibetan follower from frostbite and pneumonia. At the base camp stands a monument to the 13 who gave their lives in this great attempt. (C. G. B.)

EVERETT, ALEXANDER HILL (1790–1847), American author and diplomatist, was born in Boston, Mass., on March 19, 1790. He was the son of Oliver Everett (1753–1802), a Congregational minister in Boston, and the brother of Edward Everett. He graduated at Harvard in 1806, taking the highest honours of his year, though the youngest member of his class, and in 1807 began the study of law in the office of John Quincy Adams. In 1809 Adams was appointed minister to Russia, and Everett accompanied him as his private secretary, remaining attached to the American legation in Russia until 1811. From 1825 to 1829, during the presidency of John Quincy Adams, he was the United States minister to Spain. Everett was a member of the Massachusetts legislature in 1830–35, was president of Jefferson college in Louisiana in 1842–44, and was appointed commissioner of the United States to China in 1845. He died on May 29, 1847 at Canton, China. Everett is known rather as a man of letters than as a diplomat. In addition to numerous articles, published chiefly in the *North American Review*, of which he was the editor from 1829 to 1835, he wrote: *Europe, or a General Survey of the Political Situation of the Principal Powers, with Conjectures on their Future Prospects* (1822), which was translated into German, French and Spanish; *New Ideas on Population* (1822); *America, or a General Survey of the Political Situation of the Several Powers of the Western Continent, with Conjectures on their Future Prospects* (1827), which was translated into several European languages; a volume of *Poems* (1845); and *Critical and Miscellaneous Essays* (first series, 1845; second series, 1847).

EVERETT, EDWARD (1794–1865), American statesman and orator, was born in Dorchester, Mass., on April 11, 1794, of colonial ancestors. His father, a minister, died in 1802, and his mother removed to Boston with her family after her husband's death. At 17 Edward Everett graduated from Harvard college, taking first honours in his class. While a student he distinguished himself by his remarkable memory and his literary tastes. His earlier predilections were for the law, but the advice of Joseph Stevens Buckminster, a preacher in Boston, led him to prepare for the pulpit, and as a preacher he at once became prominent. He was called to the ministry of the Brattle street church (Unitarian) in Boston before he was 20 years old. The melody of his voice and the splendour of his images enthralled his hearers; and he further demonstrated his ability and zeal by his publication in 1814 of a volume entitled *Defence of Christianity*, written in answer to *The Grounds of Christianity Examined* (1813), by G. B. English.

Everett's tastes, however, were then, as always, those of a scholar; and in 1815, after little more than a year in the pulpit, he resigned his charge to accept a professorship of Greek literature in Harvard college. After nearly five years spent in Europe in preparation, during which time he was the first American to receive the Ph.D. degree from Göttingen, he entered with his usual industry on his duties. For five years more he won the affectionate admiration of his students and, through his lectures and sermons, the plaudits of a wider audience. He was increasingly restless in his teaching, however, and threw himself with energy into the editorship of the *North American Review* (1820–24), the influence of which he greatly extended. His election to the House of Representatives forced him to vacate his professorship, and

thereafter his career was largely political. As congressman (1825–35) he supported generally the administration of President J. Q. Adams and opposed that of Jackson, which succeeded it. He bore a part in almost every important debate, and was a member of the committee on foreign affairs during the whole time of his service in Congress as well as a member of nearly all the most important select committees, such as those on the Apportionment bill and the Bank of the United States. Although he aroused much criticism by his unnecessary defence of slavery in the event of a slave insurrection, honour is due to him for his unsuccessful opposition to the Indian policy of Gen. Jackson (the removal of the Cherokee and other Indians, without their consent, from lands guaranteed to them by treaty).

In 1835 he was elected governor of Massachusetts. He brought to the duties of the office the untiring diligence which was the characteristic of his public life. A few of the measures which received his efficient support were the establishment of the first board of education and normal school in the United States, the scientific surveys of the State (the first of such public surveys), the criminal law commission, and the preservation of a sound currency during the panic of 1837. Everett filled the office of governor for four years, and was then defeated by an exceedingly small majority, largely through the lethargy of the Whigs.

In the following spring he made a visit with his family to Europe. In 1841, while residing in Florence, he was nominated U.S. minister to Great Britain, and arrived in London upon the duties of his mission at the close of that year. Critical questions were at that time open between the two countries—the north-eastern boundary, the affair of M'Leod, the seizure of American vessels on the coast of Africa, in the course of a few months the affair of the "Creole," to which was soon added the Oregon question. Although direct negotiations were handled at Washington, Everett's conduct of his legation won the approbation of Webster and his successors and the esteem of the English court.

Immediately after the accession of Polk to the presidency Everett was recalled. From Jan. 1846 to 1849, as the successor of Josiah Quincy, he was president of Harvard college, but found disciplinary matters trying. One of the outstanding achievements of his administration was the foundation of the Lawrence scientific school, to which he brought Louis Agassiz as professor.

On the death in Oct., 1852, of his friend Daniel Webster, to whom since his school days he had been closely attached, he succeeded him as secretary of State. This post he held for the remaining months of Fillmore's administration, leaving it to go into the Senate in 1853 as one of the representatives of Massachusetts. Under the work of the long session of 1853–54 his health gave way. In May, 1854, he resigned his seat, on the orders of his physician, and retired to what was called private life. But, as it proved, the remaining ten years of his life most widely established his reputation and influence throughout America.

As early as 1820 he had established a reputation as an orator such as few men in later days have enjoyed. Careful preparation, an extraordinary memory and brilliance of style and delivery all blended to make him a superb, although possibly a too ornate, speaker. Eager to avert, if possible, the impending conflict of arms between the North and South, he prepared an "oration" on George Washington, which he delivered in every part of America. In this way he raised about $70,000 for the purchase of the old home of Washington at Mt. Vernon, adding $10,000 more to it by contributing weekly articles for a year to the *New York Ledger*. These were published in book form as *Mount Vernon Papers* (1859). Everett also prepared for the *Encyclopædia Britannica* a biographical sketch of Washington, which was published separately in 1860. In 1860 Everett was the candidate of the short-lived Constitutional-Union Party for the vice presidency, on the ticket with John Bell (*q.v.*), but received only 39 electoral votes. During the Civil War he zealously supported the national Government, was frequently consulted by the administration and was called upon in every quarter to speak at public meetings. He delivered the last of his great orations at Gettysburg, after the battle, on the consecration of the national cemetery there. On Jan. 9, 1865, he spoke at a public meeting in Boston to raise funds for the Savannah sufferers. At that meeting he caught cold, his death resulting on Jan. 15, 1865. (E. E. H.)

Everett's *Orations and Speeches on Various Occasions* was first published in 1836. Later additions resulted in a four-volume collection (1850–68). P. R. Frothingham's *Edward Everett, Orator and Statesman* (1925) is a belated but generally adequate biography.

EVERETT, a city of Middlesex county, Massachusetts, U.S.A., 3 m. N. of Boston, adjoining Chelsea. It is served by the Boston and Maine and (for freight only) the Boston and Albany railways. Pop. (1920) 40,120 (27·6% foreign-born white). It has important manufactures (notably coke and petroleum products) with an output in 1925 valued at $51,517,163. The assessed valuation of property in 1926 was $60,113,250. Everett was settled about 1630. Until 1870, when it was incorporated as a town, it was part of Malden, and was known as South Malden. In 1892 it was incorporated as a city.

EVERETT, a city of Washington, U.S.A., 28m. N. of Seattle, on Puget sound, at the mouth of the Snohomish river; a port of entry and the county seat of Snohomish county. It is on Federal highway 99, and is served by the Chicago, Milwaukee, and St. Paul and Pacific, the Great Northern and the Northern Pacific railways, and by coastwise and Oriental steamers. The population was 7,838 in 1900; 27,644 in 1920; and was estimated locally at over 37,000 in 1928.

Facing the city is Whidbey island, beyond which rise the Olympic mountains. The eastern horizon is bounded by the Cascades. Mt. Baker and Mt. Rainier stand out to the north and south. The fine land-locked harbour, with a controlling depth of 30ft. at the wharves, had in 1925 traffic amounting to 886,184 tons of cargo and 978,584 tons of floated logs, with a total valuation of $28,464,233. Coastwise shipments of lumber, logs, cedar poles, lath, shingles and paper constitute 60% of the total commerce, by value. The city has many lumber, shingle and wood-working mills, a large paper mill, several iron and steel works, railroad shops, creosoting plants, factories making machinery for saw mills and shingle mills, and salmon, fruit and vegetable canneries. The output of the factories within the city in 1925 was valued at $24,087,142. The assessed valuation of property in 1927 was $16,688,000.

Everett was settled in 1891 and incorporated in 1893. Between 1900 and 1910 its population increased more than threefold. Between 1900 and 1925 the tonnage of the commercial cargo entering and leaving its harbour was multiplied by sixteen. In 1923 the vessel traffic amounted to 1,020,622 tons, and there were also 864,838 tons of floated timbers.

Just west of Everett is the spot where Capt. Vancouver landed in June 1792. In every direction are scenic features of great beauty, including the Index mountains, Lake Stevens, Silver lake, Deception Pass State park, Monte Cristo and Snoqualmie falls.

EVERGLADES, a great saw-grass morass fringed by broad cypress swamps and savanna, and intermingled with pine-land, salt meadows and the mangrove thickets of the coast, which occupies the greater portion of southern Florida, U.S.A. The Everglades extend from the southern and south-western sides of Lake Okeechobee, one of the most prominent features of the region, with a width of nearly 50 m. and an area of 5,000 square miles. Some of the tallest and finest cypress in Florida grow along the eastern and most of the northern shores of the lake. The relief of the higher drier parts is slight indeed and the actual boundary between saw-grass morass, and cypress swamp, prairie, pine-land or coastal swamp is indefinite and devious. A rise of 2 ft. in water level may change hundreds of square miles into swamp and shallow lake. East of Lake Okeechobee the Everglades merge gradually but irregularly with the Allapattah flats, a region largely submerged by the end of each rainy season. Farther south prairies and cypress swamps border the Everglades. Westward the Everglades from Whitewater bay to Lostmans river extend to the fringing coasting mangrove thickets. The copious rainfall and slight relief of southern Florida give origin to the Everglades.

The Everglades are now being drained, part of the expense being borne by the United States, part by Florida, and part by

private land companies. A huge canal has been cut to the sea, to which laterals are being run. By the initial project 1,500,000 ac. were drained, and by other series of subsequent plans 2,500,000 ac. more would be reclaimed. The work is done at tremendous cost. Some of the land reclaimed has been occupied by settlers, and many kinds of sub-tropical fruits and vegetables are being grown. The soil, except along the shores of the lake and smaller pools where the lime from the shells of the water life has been mixed with the peat, is acid, and generally deficient in plant food.

See S. Sanford, "Topography and Geology of Southern Florida" in the Florida Geological Survey *Second Annual Report* (1909); and D. A. Willey, "Reclaiming the Everglades of Florida" in *Scientific American*, vol. cxv., No. 12 (1916). (W. E. E.)

EVERGREEN, a general term applied to plants always in leaf, as contrasted with deciduous trees which are bare for part of the year (*see* HORTICULTURE). In temperate or colder zones where a season favourable to vegetation is succeeded by an unfavourable or winter season, leaves of evergreens must possess some protection from the frost and cold drying winds, and are therefore tougher or more leathery in texture than those of deciduous trees, and frequently, as in pines, firs and other conifers, are needle-like, thus exposing a smaller surface to the drying action of cold winds. The number of seasons for which the leaves last varies in different plants; every season some of the older leaves fall, while new ones are regularly produced. The English bramble is practically evergreen, the leaves lasting through winter and until the new leaves are developed next spring. In privet also the leaves fall after the production of new ones in the next year. In other cases the leaves last several years, as in conifers, and may sometimes be found on eleven-year-old shoots.

EVERLASTING or IMMORTELLE (*Helichrysum orientale*), a plant belonging to the division *Tubuliflorae* of the family Compositae. It is a native of north Africa, Crete and the parts of Asia bordering on the Mediterranean; and it is cultivated in many parts of Europe. In common with several other plants of the same group, known as "everlastings," the immortelle plant possesses a large involucre of dry scale-like or scarious bracts, which preserve their appearance when dried, provided the plant be gathered in proper condition. The chief supplies of *Helichrysum orientale* come from lower Provence, where it is cultivated in large quantities on the ground sloping to the Mediterranean, in positions well exposed to the sun. The plant begins to flower in June. It requires a light sandy or stony soil, and is readily injured by rain or heavy dews. It can be propagated by offsets from the older stems. The flowering stems are gathered in June, all the fully-expanded and immature flowers being rejected. The plant is tufted in its growth, each plant producing 60 or 70 stems, while each stem produces an average of 20 flowers. The colour of the bracts is deep yellow. The natural flowers are used for garlands for the dead, or plants dyed black are mixed with the yellow ones. The plant is also dyed green or orange-red. Other species of *Helichrysum* and species of allied genera with scarious heads of flowers are also known as "everlastings." One of the best known is the Australian species *H. bracteatum*, with several varieties, including double forms of different colours. *H. vestitum* (Cape of Good Hope) has white satiny heads. Others are species of *Helipterum* (West Australia and South Africa), *Ammobium* (Australia) *Achyrachaena* (United States), *Antennaria* (extra-tropical except Africa), *Gnaphalium* (cosmopolitan) and *Xeranthemum* (south Europe). In North America the pearly everlasting (*Anaphalis margaritacea*) is very widely distributed, occurring in dry soils from Newfoundland to Alaska and south to North Carolina and California. Several members of the family Amarantaceae have also "everlasting" flowers; such are *Gomphrena globosa*, with rounded or oval heads of white, orange, rose or violet, scarious bracts, and *Celosia pyramidalis*, with its elegant, loose, pyramidal inflorescences.

EVERLASTING LEAGUE, a league formed in Switzerland on Aug. 1, 1291 between Uri, Schwyz and Nidwalden for the purpose of self-defence. After the defeat of Austria at the battle of Mortgarten representatives of the victorious confederates met at Brunner on Dec. 9, 1315 and a renewed treaty was drawn up, the second document being largely an expansion of the first, with the addition of certain important clauses stipulating that no government was to be recognized or negotiations made except with the consent of the three districts constituting the League. *See* SWITZERLAND.

EVERSLEY, CHARLES SHAW-LEFEVRE, 1ST VISCOUNT, cr. 1887 (1794–1888), Speaker of the House of Commons, eldest son of Charles Shaw, was born in London on Feb. 22, 1794, and educated at Winchester and Trinity college, Cambridge. He was called to the bar in 1819. In 1830 he became M.P. for Downton, in 1831, for Hampshire and in 1832 for North Hampshire. For some years he was chairman of the committee on petitions for private bills. His judicial fairness, tact and courtesy, led in 1839 to his nomination by the Liberals for the chair of the House. He was elected by 317 votes to 299, and was Speaker until 1857. The viscountcy became extinct on his death (Dec. 28, 1888).

His younger brother, SIR JOHN GEORGE SHAW-LEFEVRE (1797–1879) was under-secretary for the colonies, and one of the first civil service commissioners. He was one of the founders of the University of London, of which he was vice-chancellor for 20 years. He also helped to found the Athenaeum Club.

EVESHAM, a market town and municipal borough in the Evesham parliamentary division, Worcestershire, England, 107 m. N.W. of London by G.W. and L.M.S. railways. Pop. (1921) 8,688. On the right (north) bank of the Avon, in the rich and beautiful Vale of Evesham, the district, mainly agricultural, is devoted to market-gardening and orchards. Evesham is a place of considerable antiquity; a Benedictine house was founded here by St. Egwin in the 8th century. It became a wealthy abbey, but was almost wholly destroyed at the Dissolution. The churchyard is entered by a Norman gateway, and there survives a magnificent isolated bell-tower (1533), of the best ornate Perpendicular workmanship. A single decorated arch is almost all that remains of the abbey walls, but near the bell-tower are the parish churches of St. Lawrence (16th century) and All Saints as well as the chapel of Abbot Lichfield, who built the bell tower. Other buildings include an Elizabethan town hall, the grammar school, founded by Abbot Lichfield, and the picturesque almonry. The borough includes the parish of Bengeworth St. Peter. Evesham (Homme, Ethomme) grew up around the Benedictine abbey, and in 1055, Edward the Confessor gave it a market and the privileges of a commercial town. It is mentioned in Domesday but it is uncertain when the town first became a borough. Before 1482 the abbot practically had control of the town, and his steward presided over the court at which the bailiffs were chosen. After the Dissolution the manor, markets, fairs and other privileges were granted to Sir Phillip Hoby. In 1604 James I. granted the burgesses their first charter, but in the following year, by a second charter, he incorporated Evesham with the village of Bengeworth. Evesham received two later charters, but in 1688, that of 1605 was restored and still remains the governing charter of the borough. Evesham returned two members to parliament in 1295 and again in 1337, after which date the privilege lapsed until 1604. Its two members were reduced to one by the act of 1867, and the borough was disfranchised in 1885.

The Battle.—Evesham gave its name to the famous battle, fought on Aug. 4, 1265, between the forces of Simon de Montfort, earl of Leicester, and the royalist army under Prince Edward. As the result of the victory of Lewes (*q.v.*), the baronial party was supreme throughout most of England. Only on the Welsh March was the royal cause sustained and thither de Montfort moved, taking with him the king and Prince Edward. But at Hereford, on May 28, Edward escaped to join his adherents in the border counties. As a counterbalance de Montfort enlisted the aid of the Welsh themselves, and took the castles of Monmouth and Usk. Meanwhile, however, Edward and the royalists had secured all the bridges over the Severn in his rear, Gloucester being the last, and then moved down the west bank against de Montfort, now at Newport. They not only threw him back across the Usk but frustrated his plan of transporting his army back to England by a successful sea-raid with three galleys against the ships which he had collected at Newport. De Montfort was thus

forced to undertake a roundabout and trying march north through the barren districts of Wales, while Edward, after abandoning the pursuit, fell back to Worcester to hold afresh the Severn against him. A new factor was introduced by the approach of de Montfort's son with an army of relief from eastern England. Placed between two opposing armies, closing upon him, if gropingly, Edward showed a real and, for his time, remarkable grasp of strategy. While de Montfort himself was still some distance from the Severn, Edward left Worcester on the evening of Aug. 1, marched during the night the 30 miles to Kenilworth, where de Montfort's son lay and, taking the baronial army by surprise in the early dawn, captured and destroyed the bulk of it without resistance. Edward, without delay, countermarched to Worcester, to find that de Montfort himself had meantime ferried his army across the Severn at a point four miles south of the town. It was clear that, in ignorance of his son's defeat, he would be moving to join him at Kenilworth. Leaving Worcester once more on the evening of Aug. 3, Edward's army moved in three columns by different roads but all converging on Evesham where they would bar de Montfort's route to Kenilworth. Although the surprise was not so complete as at Kenilworth it was sufficient to give Edward an initial advantage over a hastily assembled enemy, whose first idea was that the approaching force was his son's from Kenilworth, a delusion fostered by Edward's ruse of displaying enemy banners. Caught in the bend of the river Avon by the converging columns, and surrounded on all sides, the old earl attempted to cut his way out of the town to the northward. At first the fury of his assault forced back the superior numbers of the prince; but Simon's Welsh levies melted away and his enemies closed the last avenue of escape. The final struggle took place on Green Hill, a little to the north-west of the town, where the devoted friends of de Montfort formed a ring round their leader and died with him. The spot is marked with an obelisk.

EVIDENCE, a term which may be defined briefly as denoting the facts presented to the mind of a person for the purpose of enabling him to decide a disputed question. Evidence in the widest sense includes all such facts. In the narrower sense employed in English law, however, it includes only such facts, testimony and documents as may be received in legal proceedings in proof or disproof of the facts under enquiry. Taylor applies the word to "all the legal means, exclusive of mere argument," used for such purpose; but this is too wide, since it would embrace judicial notice, presumptions of law, and inspection, which are not usually included under the term. On the other hand Stephen restricts the word to testimony and documents, exclusive of facts, which is too narrow, and, moreover, conflicts with other parts of his *Digest*, *e.g.*, an admission which by art. 15 is a relevant "fact" is declared by art. 64 to be primary "evidence"; while elsewhere, to the question "what is evidence?" it is said, "the only possible answer is that one fact is, or is not, relevant to the other."

History.—The English law of evidence as at present administered is of comparatively modern growth, having for the most part been built up by the judges in the last two centuries, with special reference to trials by jury, and it consists of this judge-made law as modified by various statutory enactments. Although, however, it was with a view to trial by untrained jurors that these rules were originally formed, and that their peculiarities are mainly to be explained, yet the sources of many of them reach back to very early times. In pre-Norman days, neither trials nor evidence in the modern sense existed. The primitive trials, or proofs, were mainly by ordeal, battle, or compurgation, which were appeals to the supernatural; while the judgments of the court respecting them, instead of following the trial, preceded it, the tribunal merely deciding by a medial judgment the preliminary questions of which litigant should have the burden of proof, and what mode of this should be adopted. The trial or "proof" then took place. If the litigant upon whom the above burden was imposed performed the task, he won; if not, he lost. But the court had no desire to hear or weigh conflicting testimony, since this would have been foreign to the whole spirit and traditions of the age. In the case of compurgation, the party himself swore, supported by a fixed number of oath-helpers who might know nothing of the facts, but merely guaranteed their principal's veracity. In a few cases, also, *e.g.*, sales and the execution of charters, pre-appointed witnesses of the transaction were employed, but these swore only in a set form and were not cross-examined. Neither compurgators, nor transaction-viewers, therefore, were witnesses in the modern sense. By the 13th century the above modes of trial had been largely superseded, both in civil and criminal proceedings, by the inquest, a Norman introduction whereby facts were determined by the sworn verdict of jurors drawn from the particular locality and personally cognizant of the matters in question. Later, this finding had, in criminal cases, to be followed by the verdict of a second jury, the former finding being treated not as testimony, but as accusation, or indictment; and it was from this embryo that the existing system of enquiry by grand jury and trial by petty jury developed. Later still, about the 15th century, the practice arose of supplementing the jury's own knowledge by information, both sworn and unsworn, from outside sources; and finally, soon after the year 1700, verdicts began in all cases, civil or criminal, to be based on the sworn testimony of witnesses given and tested in the modern way, and personal knowledge by the jurors might only be considered if delivered to the court on oath.

PRELIMINARY MATTERS

Judge and Jury. Law and Fact.—In a trial by jury two classes of questions arise, questions of law and questions of fact, but they are answered by different persons. The judge lays down the law; the jury, under his guidance, find the facts. Questions as to the production and admissibility of evidence belong to the former class; questions as to its credibility and weight to the latter. Whether there is any evidence, therefore, is for the judge; whether there is sufficient evidence is for the jury. Thus, in actions for negligence, it is for the judge to say whether from the facts proved negligence can be imputed, and for the jury to find whether it ought to be; in libels it is for the former to rule whether the words used were capable of the meaning alleged, and for the latter whether they bore it. The following matters of fact, however, are by exception determined by the judge: (1) what is reasonable in certain cases, *e.g.*, reasonable and probable cause in an action for malicious prosecution, or the reasonableness of a covenant in restraint of trade; (2) the existence of facts on which the admissibility of evidence depends, *e.g.*, those which show a confession to be voluntary, or a communication privileged; and (3) foreign law, which includes Scotch, Irish (when differing from English), and colonial law, and which, unlike English law, is treated by the courts as a question of fact to be proved by experts.

Facts Proved Otherwise Than by Evidence.—Proof in legal proceedings may be effected not only by evidence, but by Judicial Notice, Presumptions and Inspection. (*a*) Judicial Notice is the cognizance taken by the court itself of matters which are so notorious, or clearly established, that evidence of their existence is unnecessary. (*See* NOTICE.) (*b*) Presumptions are either of law or fact. Presumptions of law are arbitrary results attached by law to particular facts, and may be conclusive, as that a child under seven is incapable of committing a felony, or rebuttable, as that a person not heard of for seven years is dead, or that a bill of exchange has been given for value. Presumptions of fact are inferences which the mind naturally and logically draws from particular facts. (*c*) Inspection by the court, which is a further and valuable means of proof is, in general, allowed whenever it is reasonably practicable, and will assist the tribunal in arriving at a decision. Familiar instances thereof occur with respect to the demeanour of witnesses, the age of individuals and the comparison of handwriting or trade-marks.

Burden of Proof.—The general rule is that he who asserts a fact must prove it, and not he who denies; and this applies whether the fact is alleged in an affirmative form, as the making of a contract or the commission of a criminal act, or a negative one, as in an action for the non-repair of premises or for the unsoundness of a warranted article. In law, however, the phrase "burden of proof" has two distinct and often confused meanings,

the burden of proof as a matter of law and pleading, and the burden of adducing evidence. The burden of proof in the former sense ordinarily rests upon the plaintiff or prosecutor, though in all but the simplest cases the defendant has also one or more of the issues cast upon him. Thus, in actions of contract, the plaintiff has the onus of proving the contract, conditions precedent, breach and damages; while the defendant has the onus of facts pleaded in confession and avoidance, *e.g.*, infancy, rescission, fraud, etc. But there are two cases in which the burden of adducing evidence does not rest upon the parties above indicated: (1) when there exists a rebuttable presumption of law in favour of either party, it rests upon his opponent to rebut it, *e.g.*, a party suing on a bill of exchange need not allege, nor at the outset prove, that he gave value for the bill, or that the defendant is of full age, or sane, for the law presumes such conditions; (2) when the fact alleged is peculiarly within the knowledge of his opponent, it lies upon the latter to rebut the allegation. Indeed, many statutes expressly direct that the proof of lawful excuse or authority, or the absence of fraudulent intent, shall lie on the accused and not on the prosecution. And the Summary Jurisdiction Acts 1848 and 1879 provide that if the information or complaint in summary proceedings negatives any exemption, exception, proviso or condition in the statute on which it is founded, the prosecutor or complainant need not prove the negative, but the defendant may prove the affirmative in his defence.

Proof in Civil and Criminal Cases.—The rules of proof, though generally the same in civil and criminal proceedings, are subject to the following differences:—(1) In civil cases the rules of proof may be relaxed by consent of the parties, or order of the court; thus, the parties may elect to try their case on affidavits, may interrogate each other before the trial about the facts in dispute, and may, in some cases, obtain leave to prove facts at the trial by hearsay, or documents by secondary evidence. (2) The provisions relating to complaints, character, confessions, dying declarations and the competency of witnesses are wholly or partially peculiar to the criminal law; moreover, in criminal trials, the accused may make unsworn statements in place of, or in addition to, his sworn testimony. (3) Civil cases may be proved by a preponderance of evidence; criminal issues when arising in criminal, but not generally in civil, proceedings, must be proved beyond a reasonable doubt.

Classification of Evidence.—Bentham gives in all nine heads of evidence, but the following, which are commonly observed in practice, are all that are important. (1) *Direct, Circumstantial and Real Evidence.* By direct evidence is meant that a given fact is proved either by its actual production, or by the testimony or admissible declaration of someone who has himself perceived it. By indirect, circumstantial or presumptive evidence is meant that other facts are thus proved from which the existence of the given fact may be logically inferred. The two forms are equally admissible, and the testimony, whether to the *factum probandum*, or the *facta probantia*, is equally direct. Material objects, other than documents, produced for the inspection of the court are often called real evidence. (2) *Original and Hearsay Evidence.* The term original evidence as distinct from hearsay is used in two senses, (a) to mean the proof of facts by testimony, as opposed to their proof by statements made out of court; and (b) to mean statements made out of court which are used circumstantially, *i.e.*, as relevant irrespective of their truth or falsity, as opposed to those used testimonially, *i.e.*, to prove the truth of the facts asserted. Thus, the information on which a party has acted is often material to explain his conduct, and when tendered merely for that purpose and without reference to its truth, it is admissible as original evidence; while, if the same statement be used to prove the truth of its contents, it is hearsay and only admissible in certain clearly defined and exceptional cases. The test of whether a declaration belongs to one class or the other is, therefore, the purpose for which it is tendered. (3) *Primary and Secondary Evidence.* These terms apply to the kinds of proof that may be given of the contents of a document irrespective of the purpose for which the contents, when proved, may be used. Primary evidence may be given by production of the document, or an admission of its contents. Secondary evidence may be given by copies of various kinds (*e.g.*, Government printers' or gazette copies, office copies of judicial documents and certified copies of non-judicial ones); oral testimony by one who has read the document; and entries respecting it by deceased persons against interest, or in discharge of their duty. Copies of copies, however, are only admissible if the second has been examined with the first, and the first with the original.

The Best Evidence Rule.—The maxim that the "best evidence must be given of which the nature of the case permits," first appeared in a case decided in 1700, and for more than a century it largely regulated the subject. Thus, on the strength of this principle, circumstantial evidence used to be excluded if direct could be obtained, extrinsic proof of a party's handwriting or consent rejected if his own testimony were available, and various other forms shut out when better might be had. The rule was adopted for the prevention of fraud, it being presumed that when the best evidence was withheld, some sinister motive actuated. About the beginning of the 19th century, however, a reaction set in, and perhaps the most conspicuous feature of the modern law has been its persistent recession from this once famous principle. It began to be recognized that a prudent relaxation of strict rules tended not to encourage fraud, but to promote economy, convenience and despatch, while the risk of losing cases supplied an ample inducement to procure the best evidence available. Further inroads in the rule were made by statutes extending the competency of witnesses, or permitting secondary evidence of documents in various cases. On the other hand, strict proof is still, in certain cases, exacted, *e.g.*, of marriage in cases of bigamy and divorce, of age on a plea of infancy, and generally of the contents of a private document by its production.

FACTS

Facts in Issue. Relevancy and Admissibility.—The facts which may be proved in a judicial enquiry are facts in issue, facts relevant to the issue, and any facts, whether relevant to the issue or not, which affect the legal reception or weight of the evidence tendered. Facts in issue are those necessary by law to establish the claim, liability or defence involved in the proceedings, and which, either by the pleadings or implication, are in dispute between the parties. Facts relevant to the issue are those which render probable the existence or non-existence of a fact in issue, or some relevant fact. Although legal admissibility is for the most part based on logical relevancy, the two classes do not wholly coincide. Thus, certain facts, *e.g.*, similar occurrences, or the known character of the parties, which in ordinary life are relied on in proof of facts, the law, with certain exceptions, rejects for reasons of policy and fairness. On the other hand, numerous facts, *e.g.*, the fact that, at the date of the trial, a document was 30 years old and so proved itself, or if lost had, or had not, been searched for sufficiently to admit a copy; or that, on a charge of receiving stolen property, seven days' notice had been given to the accused so as to admit evidence of other frauds by him within the preceding five years, are legally admissible, though they may have no logical bearing on the issue. It has been suggested that the word "relevant" should be eliminated altogether, and "admissible" substituted for it throughout; but this would exchange a word which expresses the leading principle of the law of evidence, for one expressing no principle at all, but merely a collection of arbitrary rules. Both terms should, therefore, be retained, the former as indicating the guiding principle, and the latter its limits.

It is not possible satisfactorily to classify relevant facts since their variety may be infinite. But in legal trials they tend to group themselves under three principal heads or issues, dealing respectively with the existence of the main fact or transaction, the identity of the parties and the states of mind (*e.g.*, knowledge, intent, fraud or malice) of the latter with reference to the main fact.

Existence of the Main Fact. Res Gesta.—In civil cases, *e.g.*, contract or tort, the main fact is generally provable by direct testimony, or production of the documents involved; in criminal cases, however, direct evidence is less often obtainable. But in either case, what was said or done by the parties at the time, and with reference to the matter, is generally admissible as part of the

transaction, or *pars rei gestae*. Questions of evidence under this head usually arise with regard to statements, since with other incidents there is less danger of the jury being misled. Such statements must, to be admissible, have been substantially contemporaneous with the act, *i.e.*, made during, or just before or after its occurrence, but not at such an interval therefrom as to allow of fabrication or reduce them to mere narrative; they must relate to the fact they accompany, and not to prior or subsequent facts; and, though admissible to explain the transaction, or the state of mind of the parties thereto, they are no proof of the truth of the matters asserted, *i.e.*, they are original evidence, as above defined, and not hearsay admitted by exception. Among facts which, though not part of the main transaction, are relevant to prove or disprove its existence, the following should be noted: *Consistent and Inconsistent Facts, e.g.*, on a question of paternity, the resemblance or non-resemblance of the child to the alleged father; on a claim for money lent, the poverty of the alleged lender as rendering the loan improbable; or, on a claim for rent, the production of a receipt for later rent, from which it may be presumed that the earlier rent was paid. *Prior or Subsequent Existence of Facts:* In certain cases, the existence of the main fact at a given time, *e.g.*, of life, marriage, sanity, opinions, partnership, official character or domicil, may be shown by its existence prior or subsequent thereto, there being a probability that such facts continue. The presumption of continuance, which is one of fact and not of law, weakens, however, with time, and only prevails until the contrary is shown, or a different presumption arises from the nature of the case. Thus, to show that A., when taking a certain oath, had no belief in a Deity, evidence that he had no such belief four years before, was admitted, though had the interval been 30 years, the evidence would have been rejected, since the inference of continuance would then have been unreasonable. This presumption may also apply retrospectively; *e.g.*, proof that a vessel was, during a voyage and without visible cause, unseaworthy, is evidence that it was so at the time of sailing. *Course of Business:* To prove that a given act was done, it is relevant to prove that in the ordinary course of business or office it would ordinarily have been done, *e.g.*, to prove the posting of a letter, testimony by a clerk that he habitually posted the letters, though he had no recollection of the particular one, was held sufficient. *Custom:* Proof of usage is admissible to annex unexpressed incidents (not inconsistent with those expressed) to oral or written contracts, grants or wills, it being presumed that a party dealing in a particular market or place, intends to adopt its usages. Custom may be proved by the direct testimony of witnesses, or by similar instances in which it has been followed, or by reported cases in which it has been upheld, when it will be judicially noticed without evidence. *Standards of Comparison:* On questions of negligence, the acts or precautions proper to be taken under the circumstances, or the general practice of the community on the subject, are relevant. So, in cases of disputed handwriting, comparison may be made with specimens proved to the judge to be genuine, and the party whose writing is in dispute may be required to write in the judge's presence. *Acting in a capacity* is in general evidence of title thereto, even in favour of the party so acting. Thus, acting in a public office (though not usually in a private one) is admissible, even though the appointment is required to be by deed; trading as a public company is evidence of incorporation; and cohabitation evidence of a valid marriage, its weight varying with the circumstances. Similarly, title to property may be inferred from acts of ownership, *e.g.*, possession, receipt of rents, or execution of repairs; while, in rebuttal, these may be shown to have been disputed, or done in the absence of persons entitled to dispute them. *Complaints:* In cases of rape and similar sexual crimes, complaints (with their particulars) made by the prosecutrix shortly after the outrage are admissible to confirm her testimony and rebut consent, but not to prove the truth of the facts stated. Complaints in these special cases are receivable irrespective of the *res gesta* rule, which latter applies generally, but under much stricter conditions.

Identity of Parties and States of Mind.—When a party's identity with a known individual is in question, it may be proved not only by direct testimony, but presumptively by similarity of their personal characteristics or former history. When, however, a party's identity is only material as showing that he did some specific act, the range of relevant facts is much narrower. In civil cases, this question usually arises in connection with the execution of documents, and here, apart from the production of direct testimony, identity of name and handwriting will generally suffice. In criminal cases, when the occurrence of the act has been proved, the identity of the accused may be inferred from motive, means and opportunity, preparation or previous attempts, knowledge of circumstances, or possession of special skill, enabling him to do the act, or subsequent flight, change of habits, suppression or fabrication of evidence, foot-marks, finger-prints, or articles of his found at the spot, or those of others found upon him. On the other hand, the accused may rebut these, or set up an alibi, or show that the act was more likely to have been committed by the prosecutor or third persons. Neither confessions, acquittals, nor convictions of third persons are, however, evidence for, or against, the defendant for this purpose. Thus, the deathbed confession of a third person that it was he, and not the prisoner, who had killed the deceased, has been rejected in a murder trial.

States of mind as to a fact may be proved by the party's own testimony (though not by that of others), or by the facts of the transaction itself, or by matters previous or subsequent thereto. Statements made out of court and tendered for this purpose, however, are no evidence of the truth of the matter asserted, except against the party as admissions. As instances under the present head, knowledge of facts may be shown either by the party's own testimony, or presumptively from its being his duty to know, or from his having the means of knowledge; and good faith in doing an act may generally be inferred from any facts which would justify its doing.

Rules of Exclusion.—Facts, although logically relevant to the issue, are, as has been shown, not invariably admissible; and there are five classes thereof, viz., similar facts, character, privileged matters, hearsay, and opinions, which, subject to important exceptions, are shut out by as many excluding rules, either because they are too vague and uncertain to form the basis of judicial decisions, or because they would embarrass the enquiry with collateral issues, or would unfairly prejudice the parties with the jury.

(a) *Similar Facts.*—Facts which are relevant merely from their general similarity to the main fact, and not from their specific connection therewith, are inadmissible to show its existence; nor, to prove that a party did an act, may evidence be given of similar acts done by him in order to show his tendency to do such acts, and consequent probability of his having done the act in question. On the particular charge of receiving goods knowing them to be stolen, and for the purpose of showing such knowledge, an exceptional licence is allowed to the prosecution by the Larceny Act 1916, s. 43, proof being receivable (a) that other property, stolen within twelve months preceding the offence, was or had been in the accused's possession, and (b) after seven days' notice to him and proof of such possession, that he had within five years preceding the offence been convicted of fraud or dishonesty.

(b) *Character.*—When a party's character is in issue, proof must necessarily be received of what that character is, or is not. But when a party's character is tendered in proof, or disproof, of some other issue, it is usually excluded, not as being logically irrelevant, but because it is unfair to rake up a person's whole career without notice. *Exceptions:* (1) *Parties.* In criminal cases, the accused is, on grounds of humanity, allowed the privilege of proving his good character (either by his own or other testimony, or by cross-examination) for the purpose of raising a presumption of his innocence. The character proved must be of the kind impeached, *e.g.*, honesty where dishonesty is charged, and should refer to a date proximate to that of the offence. When such evidence is given, the prosecution may rebut it either by cross-examination, or by proof of the defendant's general bad character, or previous conviction for crime. Moreover, under the Criminal Evidence Act 1898, the prosecution may give such evidence not only in rebuttal of evidence of good character, but also if the

defendant has impeached the character of the witnesses for the prosecution, or given evidence against a co-defendant. In civil actions, good character, being presumed, may not (except in rebuttal) be proved in aggravation of damages; but in cases of libel, or breach of promise, the bad character of the plaintiff may be proved in reduction of damages. (2) *Third Persons*. In cases of rape, the bad character of the prosecutrix is admissible in defence; and to show consent, previous immoral acts with the prisoner may be shown by cross-examination or independent proof, and similar acts with other men may also be suggested in cross-examination, but if denied cannot be proved. In actions for seduction, or petitions for damages for adultery, the bad character of the woman betrayed may be proved in reduction of damages. And the character of the witnesses, whether parties or not, is also always admissible as affecting credit.

(c) *Public Policy and Privilege*.—Evidence of the following matters is excluded on grounds of public policy:—(1) affairs of State: *e.g.*, communications between the governor of a colony and the secretary of State; (2) information for the detection of crime: this may only be disclosed if necessary to show the innocence of the accused; (3) judicial disclosures: judges and barristers are not compellable, nor are jurors allowed, to testify as to matters arising in the discharge of their duties; (4) statements by parents bastardizing their offspring: neither the testimony, nor the statements out of court, of the parents are admissible in any legal proceeding to prove their access, or non-access, during marriage so as to bastardize their offspring, though either fact may be proved by other means. The following matters are protected from disclosure on grounds of privilege:—(1) professional confidences: a client cannot be compelled, nor a legal adviser permitted, without his client's consent, to disclose communications made between them in professional confidence. This protection, which does not extend to priests, doctors or agents, is confined to matters within the usual scope of professional employment, and such matters once privileged, are always privileged, *e.g.*, in future litigation, on change of advisers, or on the death of the client. The privilege may be waived by the client, either expressly or impliedly, though not by the adviser. But advice obtained for purposes outside the above limit, *e.g.*, to further a fraud, is not protected, even though the adviser is ignorant of the fraud. (2) Criminating questions: subject to the exceptions below, no witness is compellable to answer questions, or produce documents, tending to expose him, her, or their respective consorts, to any criminal charge, penalty or forfeiture. Answers subjecting the witness to claims for debt, or incriminating co-defendants, are not within the protection; and under the Criminal Evidence Act 1898, the Bankruptcy Act 1915, and the Larceny Act 1916, criminating answers may, with certain qualifications, be compelled. (3) Matrimonial communications: husbands and wives are not compellable to disclose communications made between them during marriage. (4) Admissions of adultery in divorce cases: in cases of divorce, but not in nullity, legitimacy or ordinary cases, witnesses are not liable to be asked or bound to answer imputations of adultery, unless they have already denied that fact in the same proceedings.

(d) *Hearsay*.—Statements, oral or written, made by persons not called as witnesses, are inadmissible to prove the truth of the the facts stated, except in the cases enumerated below. Statements made out of court may, as has been shown, be either what is awkwardly called "original" evidence, *i.e.*, where the statement is offered as relevant irrespective of its truth, or hearsay, *i.e.*, where it is offered testimonially in proof of the matters asserted. Thus, statements tendered as constituting a libel, contract, or threat, or as forming a part of the *res gesta*, or as conveying knowledge or notice, or as showing a party's good or bad faith or malice, are admissible as "original" evidence; while, an entry by a shop-man, debiting a customer with goods and tendered to prove the truth of the sale asserted, is hearsay, and only admissible in exceptional cases. The test of whether a statement belongs to one class or the other, is, therefore, the purpose for which it is tendered. The essential grounds for the exclusion of hearsay are the absence of the safeguards of oath, cross-examination, and opportunity of observing demeanour, which, in the case of witnesses, tend to ensure the reliability of their testimony. The hearsay rule is, however, subject to three important groups of exceptions:—(1) admissions, statements in the presence of a party, and confessions; (2) declarations by deceased persons made under conditions of special credibility; and (3) statements contained in public documents.

(1) *Admissions, etc.*—In civil cases, statements made by a party to the proceedings, or by a person identified in interest with him, are admissible to prove the facts stated against him, but not in his favour, otherwise everyone, when in a difficulty might make evidence for himself. Thus, in an action by A. against B. for goods, an entry by A., in his shop-books, debiting them to C., is admissible against him, but an entry debiting them to A. is not admissible for him. The circumstances of the admission may generally be proved to impeach or enhance its credibility, *e.g.*, that it was made in mistake, ignorance, levity or an abnormal state of mind, while its weight is increased by deliberation. In the special case, however, of offers of compromise made, expressly or implied by, "without prejudice," these are, on grounds of public policy, altogether excluded. When an admission is tendered against a party he may prove so much of the whole statement or correspondence as is necessary to explain it, including parts favourable to himself, but the jury may attach different degrees of credit to the different parts, and distinct matters cannot be proved in explanation. Statements made in the presence and hearing of a party, and documents in his possession, are also evidence against him of the truth of the matters stated, if by his conduct or silence he has acquiesced in their contents. Confessions made by an accused person voluntarily are evidence against him of the facts stated. (*See* CONFESSION LAW.) When property has been discovered by means of an inadmissible confession, the discovery and so much of the confession as strictly relates thereto, may be proved since this portion cannot be untrue, but the other portions will be rejected.

(2) *Declarations by Deceased Persons*.—The second main group of exceptions to the hearsay rule consists of statements by persons since deceased made against interest, or in the course of duty, or as to public rights, pedigree, or homicide, which are admissible to prove the facts stated, the truth of such statements being *prima facie* guaranteed by the special conditions imposed. In the first two cases the declarations are admissible on any issue; in the last three they are only receivable from the necessity of the case, and in proof of the particular issues named. (*a*) *Declarations Against Interest*. The interest involved must have been pecuniary or proprietary, and the declarations are evidence not only of the precise fact against interest, but of any connected facts necessary to explain it, though not against interest. Unconnected facts, however, though contained in the same statement or document are inadmissible. (*b*) *Declarations in Course of Duty*. Declarations made by the deceased in the ordinary course of duty, contemporaneously with the facts stated, and without motive to misrepresent, are admissible in proof of their contents. The duty must have been to a third person, and not a mere personal custom; and, unlike those against interest, the declarations here are only evidence of the precise matter it was the duty of the deceased to perform and record. (*c*) *Declarations as to Public Rights*. Statements by deceased persons of competent knowledge, made before dispute had arisen, are admissible in proof of ancient rights of a public or general nature, *e.g.*, rights of common, highway or ferry, or the boundaries of a parish or manor. Maps, copies of court rolls, old deeds and depositions, verdicts or judgments in former suits, are admissible under the present exception, though not awards, or unprosecuted claims. (*d*) *Declarations as to Pedigree*. On issues involving pedigree, *e.g.*, family succession (testate or intestate), relationship or legitimacy, statements by deceased relations, made before the question was controverted, are admissible. Thus, the birth, marriage or death of members of the family may be so proved if required for some genealogical purpose, but not otherwise. (*e*) *Declarations as to Homicide*. In trials for murder or manslaughter, only, the dying declarations of the deceased, made

when all hope of recovery was abandoned, are admissible to prove the cause and circumstances of his death.

(3) *Public Documents.*—The third main group of exceptions to the hearsay rule comprises statements contained in public documents, which, subject to various qualifications, are admissible, even against strangers, in proof of the facts recorded, upon the general grounds that they have been made by the authorized agents of the public, and as to matters of public interest or concern. Under this head are included statutes, parliamentary journals, the Government gazettes of London, Edinburgh and (now) Belfast, and public registers of births, marriages and deaths and the like.

(4) *Opinions and Judgments.*—The last of the classes excluded by the rules above mentioned, consists of opinion evidence, which, either in the form of general reputation, or of individual opinion and belief, is in general inadmissible to prove material facts, since if founded on no evidence, or illegal evidence, it is worthless, and if founded on legal it tends to usurp the functions of the tribunal whose business alone it is to draw conclusions of law or fact. There are, however, exceptions under each of these headings. Thus, reputation based on general opinion, but not on individual statements, is admissible in proof of public rights, pedigree, marriage, and the identification of persons referred to in libels or threats. The opinion of experts is admissible on subjects the knowledge of which requires a course of special study or experience, *e.g.*, science, art, trade, technical terms, handwriting, or foreign law. When, however, (i) the tribunal is as capable of forming an opinion as the witness, as in disputed points of duty, morality, or etiquette; or (ii.) the court is assisted by assessors, as in admiralty cases involving nautical skill, the evidence is inadmissible. (*See* ASSESSOR and EXPERT.) When opinion evidence takes the form of a judgment of a court of law, more technical rules apply; but, broadly speaking, judgments *in rem* (*i.e.*, those affecting status) are conclusive evidence of the facts actually decided, when tendered in future proceedings between either parties or strangers, while judgments *in personam* (*i.e.*, those in contract, tort, or crime) are conclusive evidence both of the fact decided and the grounds of the decision, but only between parties and those in privity with them, being in general wholly inadmissible between strangers.

WITNESSES

Attendance.—If a witness does not attend a trial voluntarily he can be required to attend in the High Court by a writ of *subpoena*, in the superior criminal courts by recognisance, or *subpoena*, and in the county courts, or before magistrates, by summons.

A witness is incompetent if, in the opinion of the court, he is prevented by extreme youth, disease affecting his mind, drunkenness, or any other cause of the same kind, from recollecting the matter on which he is to testify, from understanding the questions put to him, from giving rational answers to those questions, or from knowing that he ought to speak the truth. A witness unable to speak or hear is not incompetent, but may give his evidence by writing or by signs, or in any other manner in which he can make it intelligible.

Under the general law as it stood before the Criminal Evidence Act 1898 came into force, a person charged with an offence was not competent to give evidence on his own behalf. But many exceptions had been made to this rule by legislation, and the rule itself was finally abolished by the act of 1898. Under that law a person charged is a competent witness, but he can only give evidence for the defence, and can only give evidence if he himself applies to do so. Under the law as it stood before 1898, persons jointly charged and being tried together were not competent to give evidence either for or against each other. Under the act of 1898 a person charged jointly with another is a competent witness, but only for the defence, and not for the prosecution. If, therefore, one of the persons charged applies to give evidence his cross-examination must not be conducted with a view to establish the guilt of the other. Consequently, if it is thought desirable to use against one prisoner the evidence of another who is being tried with him, the latter should be released, or a separate verdict of not guilty taken against him. A prisoner so giving evidence is popularly said to turn king's evidence. It follows that, subject to what has been said above as to persons tried together, the evidence of an accomplice is admissible against his principal, and vice versa. The evidence of an accomplice is, however, always received with great jealousy and caution. A conviction on the unsupported testimony of an accomplice may, in some cases, be strictly legal, but the practice is to require it to be confirmed by unimpeachable testimony in some material part, and more especially as to his identification of the person or persons against whom his evidence may be received. The wife of a person charged is now a competent witness, but, except in certain special cases, she can only give evidence for the defence, and can only give evidence if her husband applies that she should do so. The special cases in which a wife can be called as a witness either for the prosecution or for the defence, and without the consent of the person charged, are cases arising under particular enactments scheduled to the act of 1898, and relating mainly to offences against wives and children, and cases in which the wife is by common law a competent witness against her husband, *i.e.*, where the proceeding is against the husband for bodily injury or violence inflicted on his wife. The rule of exclusion extends only to a lawful wife. There is no ground for supposing that the wife of a prosecutor is an incompetent witness.

Oaths.—Except in the case of children, when very young, witnesses merely producing documents, or counsel and judges explaining cases in which they have been professionally concerned, oral evidence must be given under the sanction of an oath, or solemn affirmation, the form of which will differ according as the witness has, or has not, a religious belief. A believer must be sworn either in the usual way, or in some other that he declares to be binding, unless he states that an oath is contrary to his religion, when he will be allowed to affirm. If, however, he objects on grounds other than the above, or will not state what form of oath is binding on him, his testimony will be excluded. The testimony of an atheist is admissible if he has been sworn without objection, or has been allowed to affirm because he has no religious belief.

Witnesses at the trial of any action or criminal charge must in general give their evidence *viva voce*, and in open court; but in certain statutory cases, and in proceedings affecting lunatics and wards of court, or where publicity would defeat the ends of justice, the hearing may be had *in camera*.

Examination.—The normal course of procedure is this. The party who begins, *i.e.*, ordinarily the plaintiff or prosecutor, calls his witnesses in order. Each witness is first examined on behalf of the party for whom he is called. This is called the examination in chief. Then he is liable to be cross-examined on behalf of the other side. And, finally, he may be re-examined on behalf of his own side. After the case for the other side has been opened, the same procedure is adopted with the witnesses for that side. In some cases the party who began is allowed to adduce further evidence in reply to his opponent's evidence.

In the examination in chief questions must be confined to matters bearing on the main issue, and a witness must not be asked as to facts protected by public policy or privilege, nor must material matters in general be elicited by leading questions, *i.e.*, questions suggesting the answer which the person putting the question wishes or expects to receive, or suggesting disputed facts about which the witness is to testify. But the rule about leading questions is not applied where the questions asked are simply introductory, and form no part of the real substance of the inquiry, or where they relate to matters which, though material, are not disputed. And if the witness called by a person appears to be directly hostile to him, or interested on the other side, or unwilling to reply, the reason for the rules applying to examination in chief breaks down, and the witness may be asked leading questions and cross-examined, and treated in every respect as though he was a witness called on the other side, except that a party producing a witness must not impeach his credit by general evidence of bad character (Evidence and Practice on Criminal

Trials Act 1865). A witness under examination may refresh his memory by referring to any writing made by himself at or about the time of the occurrence to which the writing relates, or made by any other person, and read and found accurate by the witness at or about the time. An expert may refresh his memory by reference to professional treatises.

In cross-examination questions not bearing on the main issue and leading questions may be put and (subject to the rules as to privilege) must be answered, as the cross-examiner is entitled to test the examination in chief by every means in his power. The licence allowed in cross-examination has often been seriously abused, and the power of the court to check it is recognized by one of the rules of the supreme court (R.S.C. xxxvi. 39, added in 1883). It is considered wrong to put questions which assume that facts have been proved which have not been proved, or that answers have been given contrary to the fact. A witness ought not to be pressed in cross-examination as to any facts which, if admitted, would not affect the question at issue or the credibility of the witness. If the cross-examiner intends to adduce evidence contrary to the evidence given by the witness, he ought to put to the witness in cross-examination the substance of the evidence which he proposes to adduce, in order to give the witness an opportunity of retracting or explaining. Where a witness has answered a question which only tends to affect his credibility by injuring his character, it is only in a limited number of cases that evidence can be given to contradict his answer. Where he is asked whether he has ever been convicted of any felony or misdemeanour, and denies or refuses to answer, proof may be given of the truth of the facts suggested (28 & 29 Vict. c. 15, s. 6). The same rule is observed where he is asked a question tending to show that he is not impartial. Where a witness has previously made a statement inconsistent with his evidence, proof may be given that he did in fact make it. But before such proof is given the circumstances of the alleged statement, sufficient to designate the particular occasion, must be mentioned to the witness, and he must be asked whether he did or did not make the statement. And if the statement was made in, or has been reduced to, writing, the attention of the witness must, before the writing is used against him, be called to those parts of the writing which are to be used for the purpose of contradicting him (Evidence and Practice on Criminal Trials Act 1865, ss. 4, 5). The credibility of a witness may be impeached by the evidence of persons who swear that they, from their knowledge of the witness, believe him to be unworthy of credit on his oath. These persons may not on their examination in chief give reasons for their belief, but they may be asked their reasons in cross-examination, and their answers cannot be contradicted. When the credit of a witness is so impeached, the party who called the witness may give evidence in reply to show that the witness is worthy of credit. When an accused person offers himself as a witness, he may be asked any question in cross-examination, notwithstanding that it would tend to criminate him as to the offence charged. But he may not be asked, and if he is asked must not be required to answer, any question tending to show that he has committed, or been convicted of, or been charged with, any other offence, or is of bad character, unless:— (i.) the proof that he has committed, or been convicted of, the other offence is admissible evidence to show that he is guilty of the offence with which he is then charged; or, (ii.) he has personally, or by his advocate, asked questions of the witnesses for the prosecution, with a view to establish his own good character, or has given evidence of his good character, or the nature or conduct of the defence is such as to involve imputations on the character of the prosecutor or the witnesses for the prosecution; or, (iii.) he has given evidence against any other person charged with the same offence. Nor may he be asked questions tending to criminate his wife.

Re-examination must be directed exclusively to the explanation of matters referred to in cross-examination, and if new matter is, by the permission of the court, introduced in re-examination, the other side may further cross-examine upon it.

Number of Witnesses and Corroboration.—As a general rule courts may act on the testimony of a single witness even though uncorroborated; or upon duly proved documentary evidence without such testimony at all. But whenever there are circumstances of suspicion, or the testimony of a witness is challenged by cross-examination or otherwise, corroboration is allowed, and in certain cases no verdict can be obtained without it. Thus, on charges of treason, or personation at elections, two witnesses are essential; in cases of perjury, breach of promise or bastardy, one witness will only suffice if corroborated in material particulars; and where proof of an offence rests on the unsworn testimony of children, corroboration is also required. In the above instances, the rules are statutory; but by a rule of practice, though not of strict law, corroboration is also needed in claims to the property of deceased persons, and in criminal cases, of the testimony of accomplices.

Protection of Witnesses.—A witness is privileged from arrest on civil process while he is in attendance on a court of justice, or is on his way to or from the court (*eundo, morando et redeundo*); but the privilege does not exempt from arrest on a criminal charge. And it is a contempt to threaten, bribe, or coerce a witness with intent to influence or prevent his evidence. Moreover, on grounds of public policy, no action will in general lie against a witness in respect of the testimony given by him in court.

DOCUMENTS

Questions of evidence under this head may arise with respect to the execution, contents, supersession, variation or interpretation of documents.

Execution.—As to execution, public or judicial documents are sometimes (*e.g.*, in the case of statutes or letters-patent) judicially noticed on their mere production; in other cases they may require no further authentication than that of appearing in a Government gazette, or of "purporting" to be printed by official printers, or to be certified, signed or sealed by some court or public department. The execution of private documents is proved by evidence of their signature given by the writer, or some person who saw it signed or knows the writing, as explained above; or, if the document is required by law to be attested, by calling the attesting witness, unless it is 30 years old and produced from proper custody, when it proves itself; or by the admission of the party against whom it is tendered; or by comparison, made by experts or other witnesses, of the documents in question with genuine specimens of the writing. (*See* HANDWRITING.)

Contents.—The contents of public or judicial documents may be proved either by ordinary evidence (*i.e.*, production or admission) or, more usually, by secondary evidence, which may consist here of Government printers' copies, Government gazette copies, certified copies (in the case of non-judicial documents such as registers), or office copies (in the case of judicial documents), but not of oral evidence. The contents of private documents must be proved by primary evidence, as above, except where (1) the original is lost or destroyed; or (2) its production is impossible or highly inconvenient, as in the case of registers, tombstones, or documents in a foreign country; or (3) when the original is in the possession of a stranger who refuses, and is not compellable by law, to produce it; or (4) when the original is in the possession of the opponent, who refuses to produce it either after notice to produce, or when such notice is excused, which occurs when the document is itself a notice to the opponent, or the latter is charged, in the same case, with its possession, or has it in court, or has admitted its loss. When, under the above exceptions, secondary evidence of a private document is admissible, such evidence may consist of an examined copy (*i.e.*, one sworn to be true by a witness who has examined it, line by line, with the original, the copies used in proof of public documents not being applicable here); or of oral testimony by witnesses who have read the document; or of entries as to its contents made by deceased persons against their pecuniary interest, or in the discharge of duty; or of presumptive evidence, *e.g.*, proof that parties who had interests under the document had acted in accordance with its tenor.

Supersession.—With regard to the supersession of documents,

the rule is that if a transaction has been reduced to a documentary form, either by requirement of law or agreement of the parties, the terms of the transaction must be proved by production of the document, or an authenticated copy thereof, and not by oral evidence, even though the oral and written terms may be identical, or the oral terms have been acted upon before reduction to writing. The party whose witnesses show that the transaction was reduced to writing must produce, or explain the absence of the instrument; and the opponent, in order to ascertain the fact, may either interpose in chief, or reserve the question for cross-examination, or, if the document be denied, may at once prove its existence. Where, however, the plaintiff can establish a *prima facie* case without disclosing the document, he will not be prejudiced by the defendant proving its existence, for the burden will then be shifted, and if the latter rely on the document he must produce it as part of his own case (with the usual liability as to stamping), even though he has served a notice to produce it on the plaintiff. When the mere existence of a transaction, irrespective of its terms, is in question, this may generally be shown by parol, without production of the document, *e.g.*, the existence of a partnership or official appointment.

Contradiction and Variation.—The rule here provides that when a transaction has been reduced into writing by requirement of law, or agreement of the parties, parol evidence (*i.e.*, oral or written matter extrinsic to the document) is in general inadmissible to contradict, vary, enlarge, or restrict the written terms. The grounds of exclusion commonly given are that where the law requires superior evidence, to admit inferior would be to nullify the law; and that where the parties have deliberately put their agreement into writing, it is conclusively presumed between themselves and those in privity with them that they intended it to be a full and final statement of their intentions, and one which should be placed beyond the reach of future controversy, bad faith, or treacherous memory. The rule, however, is sometimes thought to be based on the "best evidence" principle, though historically it is in fact much older; sometimes on the doctrine of estoppel; and sometimes wholly on the substantive law. It is subject to the following exceptions, in some of which parol evidence is admitted wholly to contradict the document, and in others merely to supplement it, but without contradiction. Thus (1) public documents, *e.g.*, entries in a register of the tonnage of a ship, are in general given no exclusive authority by law as instruments of evidence, and may be contradicted or varied by parol. (2) Extrinsic evidence is in general admissible to show the true nature of a transaction, or the legal relationship of the parties, although such evidence may contradict or modify the instrument. Thus, a sale, absolute on its face, may be proved by parol to be a loan, a conveyance merely a mortgage, an unqualified devise subject to a secret trust, or a receipt in, or indorsed on, a deed, contradicted. Fraud, or mistake may be similarly established, though the document is thereby impeached. (3) Where a contract, not required by law to be in writing, has been reduced thereto, but the court infers that the document was not intended to contain the whole agreement between the parties, proof may be given of any omitted term expressly or impliedly agreed between them at or before the execution of the document, and not inconsistent therewith. The question whether the document was intended to contain the whole agreement may be determined either by the document itself, or by extrinsic circumstances, and may be left to the jury. Moreover, although there exists a contract purporting to be fully expressed in writing, whether required by law to be so or not, proof may be given of a prior or contemporaneous oral agreement or warranty, if it forms part of the consideration for the main contract, and is not inconsistent with the document. The collateral contract must be between the same parties, and not include others as well. Apart, however, from such omitted or collateral terms, unexpressed incidents, if not inconsistent with those expressed, may be annexed to contracts, grants, or wills, either by usage, for here it is presumed that the customs of the particular market or place have been tacitly adopted by the parties, or by law, in which case the incidents annexed will be judicially noticed without resort to evidence, and may in some cases (*e.g.*, in contracts under the Sale of Goods Act 1893, s. 55) be varied or contradicted by parol. (4) Written contracts, if not required by law to be in writing, may at any time before breach, be either rescinded or modified by parol; if required by law to be in writing, they may be wholly rescinded by a parol agreement, even though such agreement may itself be unenforceable, but not partially abandoned or varied thereby. Deeds may be discharged, but not varied, by oral agreement made for valuable consideration; bills and notes may be discharged by writing, or delivery up; and wills may be revoked by later wills, or destruction animo revocandi, or modified by further testamentary instruments.

Interpretation.—When the language of a document is clear and applies without difficulty to the facts of the case, extrinsic evidence is not admissible to affect its interpretation; but when the language is peculiar, or its application to the facts is ambiguous or inaccurate, extrinsic evidence may, subject to the under-mentioned rules, be received to explain it.

Rule i. (surrounding circumstances).—In order to show the identity or extent of the objects referred to in a document, extrinsic evidence (including the knowledge and surrounding circumstances of the writer, his treatment of, and habits of speech concerning, such objects, but not his direct declarations of intention) may be given. The principle is that, as most documents refer to the circumstances under which they were written, the court, in interpreting them, should be placed as nearly as possible in the same situation as the writer; while, as to the degree of certainty required, the maxim *id certum est quod certum reddi potest* applies. Such evidence, however, is not admissible when the ambiguity is merely a grammatical one, or when the language is so vague or imperfect that no reasonable meaning can be attached to it, so that to admit evidence would be, not to interpret the document, but virtually to make a new one. Thus, where A. appointed as his executor "Percival —, of Brighton, the father," evidence that A. had two friends called Percival B., father and son, and both of Brighton, was received, and probate granted to the former. While, where A. left legacies to "Mr. —," and "Lady —," extrinsic evidence to fill the blanks was rejected, the language being wholly defective and uncertain. So, where A., a farmer, sued B. on a contract signed by B. "to take your wool at 16s. a stone," a letter from A. to B.'s agent, before the contract, that he "had sold part of his own clip, but was promised other wool which would go with his own," was received to show that in the contemplation of the parties "your wool" included both clips, and not A.'s clip only.

Rule ii. (primary and secondary meanings, correct and less correct names and descriptions).—When the words of a document in their primary or ordinary sense, are applicable to the facts and not modified by the context, extrinsic evidence cannot be given to show that they were not used in that sense; but when it is clear from the context, or the facts, that such meaning cannot have been intended, extrinsic evidence of the kinds above specified may be given to show that they were used in some secondary or less ordinary sense, provided it is one which the words can properly bear. Rule i. included cases where the words, being of a vague or general character, were equally applicable to a wide or narrow meaning. The present rule deals with words having a proper and also a less proper sense or application. Thus, words of relationship import legitimate relationship; if, therefore, legitimate members exist, evidence cannot in general be given that illegitimates were intended; though if none do or can exist, or if, though some exist, the context may include the latter, the evidence will be receivable. Again, if a given person, known to the testator, accurately fulfils the words in the will, and there is no other claimant, evidence cannot be given that he was not intended; and if one of two claimants fulfils the words and the other not, evidence in favour of the latter will be rejected. So, also, in cases of property, if a subject exists satisfying all the written terms, evidence cannot be given that something more or less extensive was intended. As instances of the foregoing, where A. left property to his "children," having none of his own, but only step-daughters, evidence that they lived with him, adopted

his surname, were known by the neighbours as his children, and were so treated and called by him, was received in their favour; while where A. left property to B's "children," B. having both legitimate and illegitimate issue, evidence that A. treated and promised to provide for them all alike was rejected, and the legitimates alone held entitled.

Rule iii. (incorrect names and descriptions).—When the words of a document apply in part correctly and in part incorrectly to a single subject-matter, extrinsic evidence of the kinds stated in Rule i. may be given to show whether they were intended by the writer to apply to it, or not; and when the words apply partly to one subject and partly to another, but correctly to neither, similar evidence may be given to show which of the two was intended, the maxim *falsa demonstratio non nocet cum de corpore constat* applying. Thus, where a voting paper beginning "I, the undersigned A." was signed "B.," evidence by the town clerk that he gave A.'s paper by mistake to B. who signed it without noticing the mistake, was admitted to explain the patent ambiguity and validate the vote. So, where A. left a legacy to "my dear wife C.," evidence that his wife, from whom he was separated, was called M., but that he had bigamously married C., who was living with him at the dates of his will and death, was received and the legacy given to C.

Rule iv. (equivocations).—Where the words of a document, though intended to apply to one object only, apply equally to more, and it is impossible to gather from the context which was intended, an equivocation arises, and in addition to the evidence admissible above, direct declarations of the writer's intention may be given to solve the ambiguity. An equivocation may arise where the same name or description fits two objects accurately; or one accurately and the other popularly though less accurately, *e.g.*, the same name borne by father and son; or one accurately and the other in a transposed order, or with additional names. There is no equivocation, however, where there are legitimate and illegitimate relations of the same degree, for the case then falls under Rule ii. above; nor where part of a name or description applies to one object and the remainder to another, for the case then falls under Rule iii.

Rule v. (usage, experts, dictionaries).—Where the words of a document have a double meaning, the one common and the other local or peculiar, evidence of the latter is admissible, if the context, or facts, point to such a user by the parties. And the testimony of experts, or a reference to dictionaries, is similarly admissible to explain local, technical or foreign terms.

EFFECT OF EVIDENCE

Weight of Evidence. Presumptions and Estoppels.—The probative weight of evidence, unlike its admissibility, is determined not by arbitrary rules, but by the natural acumen, good sense and experience of the tribunal. Independently of this, however, valuable aid in deciding cases is provided by the rules as to burden of proof, *e.g.*, where the scales are even, the plaintiff or prosecutor, and not the defendant, must lose, since the former will, if the case be a civil one, have failed to establish his case by a preponderance of probability, or, if it be a criminal one, by proof of guilt beyond a reasonable doubt. So, where either party has a rebuttable presumption of law in his favour, he must win, unless his opponent can specifically rebut it.

An estoppel is a rule whereby a party is precluded from denying some state of facts which he has previously asserted. It is usually said to be a rule of evidence, since an action cannot be founded thereon; but as a defence can, and as estoppels must be pleaded and evidence must not, this statement is not wholly satisfactory. Estoppels have been variously treated as conclusive presumptions of law, as solemn admissions, and as conclusive evidence. They are, however, distinguishable from the first in that an estoppel may be waived; from the second as well as from the first, in that it cannot in general be taken advantage of by strangers; and from the third, in that the conclusiveness of evidence may result from mere logical cogency, while, when it results from some rule of law, it operates against strangers as well as parties. Estoppels of all kinds, however, are subject to one general rule, they cannot over-ride the law. Thus, where writing is required by statute, no estoppel will cure the defect; an infant is not estopped by his fraudulent statement that he is of full age; nor is a corporation estopped by acts which are *ultra vires*. Estoppels may arise (1) by record: *e.g.*, judgments or letters-patent; (2) by deed: thus where a party has by deed agreed upon certain facts, neither he, nor those in privity with him, are permitted to deny them. This, however, applies only to actions on the deed, and to recitals or descriptions which are material and intended to bind; (3) by agreement: *e.g.*, a landlord is estopped from denying his title to the premises let, and a tenant from denying the title of his landlord, or the latter's heirs; a bailee is estopped from denying his bailor's authority to make the bailment; and the licensee of a patent from denying the validity of the patent; (4) by representation: the rule here is that when a party has, by his words or conduct, wilfully induced another to believe in certain facts and to alter his position in consequence of such belief, the former is estopped from denying their existence. (*See* TESTIMONY, PSYCHOLOGY OF.)

THE UNITED STATES

The law of evidence in the United States, even where legislatively codified, is mainly derived from the corresponding branch of English common law. Importations from other legal systems, such as presumptions with respect to survivorship in common disasters, are rare and not of great significance. But the American nation contains some 50 jurisdictional units, State and Federal, each presenting much evidence which is a plain departure from the English system. A late United States treatise on evidence cites about 80,000 decisions, of which only a minority come from England. In recent English digests few cases are listed at the points where evidence is discussed; in corresponding American digests many cases are so listed. Mere numerical comparison is somewhat misleading, because in the United States digesting is highly detailed and more cases are reported than in the older country. Even after full allowance on these points, the multiplicity of American evidential decisions, both absolutely and in comparison with those on other legal topics, indicates that forces tending to complexity may be found in the law itself, or in the manner of administration, or in both.

COMPLICATING FACTORS

Functions of Judge and Jury.—The law of most States largely or completely prevents trial judges from commenting to juries upon the relative weight or credibility of testimony presented by contending parties. While the avowed purpose of the restriction is to keep judges from subduing jurors' independent judgment, an incidental effect is to deprive inexperienced jurymen of guidance by trained minds. It is warmly debated whether the benefits of the rule can outweigh its detriments. This restrictive doctrine has effect among cautious judges, even beyond the jurisdictions which have adopted it. Many cases are reported in which trial judges are charged with having overstepped the deadline; in others, not always reported, judges who lacked original

power to hold juries within reasonable bounds have felt compelled to set verdicts aside as against the weight of the evidence, and grant new trials. Another allied peculiarity, while scarcely so wide-spread, deserves mention. The conventional common law view has long been that the trial judge, and not the jury, should determine disputes of fact upon which admissibility of evidence depends. So, where a culprit objects to the admission of his confession, claiming it to have been involuntary, the judge normally decides whether or not the statement has been improperly extorted. But under a common American view the judge who admits a confession as voluntary may or must submit over again to the jurors the same preliminary question, instructing them to discard the confession unless they too find it to have been voluntarily made. A similar attitude has been taken with respect to the determinations of fact necessarily preliminary to admission of alleged dying declarations. These illustrations relate to the use of evidence against criminal defendants, and certainly this departure from common law conventions is most frequently encountered in that connection. The resulting complication in the handling of evidence gives rise to considerable controversy before both trial and appellate courts.

Questions of Competency and Privilege as to Witnesses.—The United States, like England, has legislated out of existence many old rules respecting incompetency of witnesses which stood upon outworn historical bases partially obscured by subsequent invention of feeble logical justifications for the rules. But the legislation has not been uniform, and some startling vestiges of ancient disabilities remain. There are courts where one spouse is incompetent to testify in the other's favour. In Federal criminal prosecutions Congress has left the principles of competency so obscure that judges are puzzled, and fundamentally inconsistent lines of cases flourish. Many State legislatures have deliberately preserved a fragment of the old incompetency affecting parties and interested persons. The reference here is to the so-called "dead man" statutes, which seek to protect the estates of decedents from trumped-up claims by survivors. As an illustration, the Nebraska statute says "No person having a direct legal interest in the result of any civil action or proceeding, when the adverse party is the representative of the deceased person, shall be permitted to testify to any transaction or conversation had between the deceased person and the witness." Sometimes similar protection is extended to insane persons; sometimes there are express or implied provisions for waiver by the legal representatives of the person protected. If the topics touched upon under the functions of judge and jury indicate a distrust of judges, the present topic indicates a distrust of the jurors' power wisely to discount evidence given against the interests of those whose lips are sealed by death. A few States do not exclude the testimony of survivors, but require this testimony to be corroborated or relax the hearsay rule with respect to declarations by decedents. The "dead man" statutes figure extensively in litigation.

English law recognizes certain classes of privileged communications, as, for example, between husband and wife and between lawyer and client. More than half the jurisdictions in the United States by statute give privilege to penitential confessions made to a priest, clergyman, or minister. This legislation seems sound. Very often privilege has been extended to communications between physician and patient. Many qualified persons vigorously challenge the wisdom of this last privilege, denying that it makes medical consultation more frequent or frank. The ramifications of the physician-patient privilege have distinctly complicated legal proceedings. Occasionally it has harmed the person it was meant to protect; for instance, where an executor lost favourable testimony from the testator's own physician in an action on a life insurance policy, the court holding that the patient alone could remove the seal of privilege.

The privilege against self-incrimination is enforced in the United States, always or almost always under constitutional provisions. There have been elaborate controversies whether the privilege is violated if a prisoner be required to stand up or speak in court for purposes of identification, to put on a coat, cap, or other garment found at the scene of the crime, or to put his foot or shoe in a track left on the ground. Decisions on such points vary and some refined distinctions have been taken. Generally it is not permissible for either the prosecutor or the trial judge to comment adversely upon a culprit's failure to take the stand in his own behalf. The prosecutor often yields to the temptation to break this prohibition. Numbers of cases involving the point are carried to upper courts after convictions. In certain offences, notably those involving many actors, it is desirable to have means for compelling selected offenders to turn State's evidence. With this end in view, statutes frequently provide that a person may be required to testify respecting such offences, but thereafter either his testimony may not be used against him or he shall be immune from prosecution for the acts he is forced to disclose. Conflicts of authority exist as to the constitutionality of such legislation.

Evidence Illegally Obtained by Government Officers.—Authoritative early American decisions held documents and other tangible evidential material none the less admissible because the offering party had obtained them by illegal means. He might be subject to an action for conversion or a prosecution for larceny, but the possibility of such independent proceedings had no bearing upon the immediate problem of admissibility. This rule was generally taken for granted until after the close of the 19th century. As early as 1886, however, the U.S. Supreme Court made a decision destined to cause wide-spread change. In a Federal information for an alleged revenue fraud the U.S. attorney under statutory provisions compelled the defendant to produce a certain material document. A majority of the Supreme Court held the statute unconstitutional as purporting to authorize an unreasonable search and seizure, and also as violating the privilege against self-incrimination; a minority of two justices differed on the search and seizure point, but concurred as to the self-incrimination. The possibilities of this decision were not much developed for nearly 30 years. Then in a criminal prosecution the same court unanimously held that the trial judge had erred by denying before trial the defendant's petition for return of papers seized in his home by a U.S. marshal without a search warrant or other legal justification, and by admitting these papers at the trial. Further developments marched swiftly and steadily. Case after case before the U.S. Supreme Court suggested multitudinous variants of the original situations. In 1928 an important decision held that evidence of a conspiracy which Federal officials obtained by illegally tapping telephone wires was not inadmissible; four of nine justices dissented. The Federal adjudications led to reconsideration of the old rule by the highest courts of practically all the States. Some of these tribunals embraced the new doctrine under the provisions of local Constitutions applicable to the acts of local officials. The output of cases involving illegally seized evidence has been enormous. Public interest has become excited, particularly because enforcement of the acts prohibiting intoxicating liquor is deeply involved. This episode in the struggle between old-time individualism and growing government regulation is the most spectacular recent development of the American law of evidence.

Confessions.—For years claims have been made that police and prosecutors were wringing confessions from prisoners by promises, threats and actual torture. It is difficult to evaluate properly these claims. On the one hand, accused men trying to escape criminal penalties are unreliable witnesses; on the other, the captors have incentive and power to keep more acceptable adverse witnesses from gaining first-hand knowledge of any such illegal actions. But from judicial decision and from admission by some police officers it is indubitable that these improper activities do largely occur. In 1924 the U.S. Supreme Court reversed a murder conviction for admission of an extorted confession. By way of extenuation, police authorities urge that criminals' interests have been so safeguarded as to make convictions almost unobtainable without use of the so-called "third degree." High quarters have suggested that the situation would be bettered by abolishing or modifying the privilege against self-incrimination.

Opinion Evidence.—Many American cases deal with the fundamentally simple rule excluding certain types of opinion evidence. The situation with respect to expert witnesses is not altogether satisfactory. While the English exceptions to the rule

barring hearsay evidence are mainly identical with those recognized by U.S. courts, the younger country has forced one interesting development which has common sense merits, although it adds to the difficulties of administration. The most frequently cited pioneer case comes from the U.S. Supreme Court. In an action on insurance policies covering the life of A., the underwriters claimed that A. was still living, and that a body produced as A. was really B., whom A. had enticed away and killed to carry out the fraud. The underwriters offered evidence that B. had disappeared and that about the time of his disappearance he had declared in letters an intention to go on a long trip with A. The Supreme Court held that the trial judge had erroneously excluded evidence of the contents of these letters. Under what is now in America a recognized exception to the hearsay rule, the usual expressions of mental condition are competent evidence wherever such condition is material to be proved. The opinion says: "The letters in question were competent . . . as evidence that, shortly before the time when other evidence tended to show that he (B.) went away, he had the intention of going, and of going with Hillmon (A.), which made it more probable both that he did go and that he went with Hillmon, than if there had been no proof of such intention." In the foregoing case the inference was forward from a declaration of present state of mind (intention) to the doing of a future act. Why not infer backward from a declaration of another present state of mind (memory) to the doing of a past act or the existence of a past fact? But if the latter inference be allowed, the hearsay rule is practically erased. Some American courts have carried the doctrine of this case to extremes, but the majority are still within reasonably conventional bounds. It has been necessary, however, in making saving differentiations to employ arguments of a complicated psychological nature, scarcely fitted to the rapid progress of court trials.

General Considerations Affecting Evidence in the United States.—To the foregoing brief survey should be added some general considerations. (1) As the American legal profession is undivided into barristers and solicitors, many cases are tried by lawyers comparatively inexpert in the handling of evidence. (2) In America there is too little spontaneous manifestation of the English doctrine allowing relaxation of the rules of proof by mutual consent or court order. (3) The American trial judge usually does not, and perhaps cannot, drive on so tight a rein as the English trial judge. (4) The United States' scale of fees and costs is pitched so low that litigants can afford to take chances with points not worth while in England. (5) Not all American appellate courts insist upon substantial error as a basis of reversal; occasionally dry technicalities are accepted. These factors have caused the habit of arguing and carrying up cases on evidential points.

RATIONALIZING FACTORS

As a result, there is general distrust of the rules of judicial proof. The lay public is not sufficiently informed about defects and debatable points to express more than blanket condemnation. Many in the legal profession display a perfectly comprehensible complacency; familiarity with the mysteries of a great profession breeds tolerance far more often than contempt. But a considerable amount of constructive criticism emanates from both bar and bench. Another significant group for initiating reforms is composed of law teachers. These are critical because they keep up with comparative law. Between 1842 and 1853 Prof. Simon Greenleaf, of the Harvard law school, published the first great American work on evidence. It has gone through 16 editions, has had vast influence, and is constantly cited. Incidentally, it is the basis of Taylor's English treatise. In 1898 Prof. J. B. Thayer, also of Harvard, published his *Preliminary Treatise on Evidence at the Common Law.* This showed that many rules were outworn or misconceived, carefully discriminated between evidence and other branches of the law, and offered recommendations for the former's improvement. Thayer's was a lonely voice, but as a teacher he influenced hundreds of nascent lawyers. After the death of Thayer one of his students, now Dean J. H. Wigmore of the Northwestern university law school, published a comprehensive scientific study in 1904–05. Prof. J. C. Gray said that it was "the greatest law book since Benjamin on *Sales.*" Its effect on American law has been profound. By sharp, thorough analysis and pungent comment, Wigmore has forced even his opponents to reframe their arguments. He has attracted fresh and powerful minds to the field of evidence, and lifted the dead hand of subservience to history merely because it is history.

SPECIFIC IMPROVEMENTS

Some definite seeds of improvement in the American law of evidence are to be found in some already accepted modifications, in the growth of special tribunals, and in the influence of logical experimentation.

Judicial Notice.—No fewer than 13 States have simplified the problem of proving foreign law as a fact by providing that their courts may or shall take judicial notice of the law of some or all foreign jurisdictions. Commentators have praised the Massachusetts act on the point, which was recommended by that State's judicial council: "The courts shall take judicial notice of the law of the United States or of any state, territory or dependency thereof or of a foreign country whenever the same shall be material."

Res Gestae.—The indeterminate doctrine of *res gestae* degenerated into a formless welter at the hands of American courts. Mr. Justice Holmes, faced with the phrase as a ground for admitting certain evidence, is reported to have said: "I prefer to give articulate reasons for my decisions." Commentators have dissected the tangled mass of cases, enlisted the practical aid of judges, and begun to produce at least partial order and comprehensibility. Wigmore extracted a distinct hearsay exception for spontaneous declarations under emotional pressure which is being widely accepted.

Exceptions to the Hearsay Rule.—English law recognizes a group of hearsay exceptions for declarations by deceased persons under conditions of special credibility. A helpful tendency in the United States is expanding these exceptions to cover similar declarations by persons who, although still living, are insane, out of the jurisdiction, or otherwise unavailable as witnesses. Largely through Wigmore's influence, the judges are liberalizing the doctrine of business entries, admitting records covered by this description without demanding meticulous verification. Only key men who can describe the general process of recording are required to be called. This is a boon as it shortens trials and prevents expensive interruption of work in industry. In 1896 Prof. Thayer made a suggestion which caused the Massachusetts legislature to pass the following act: "No declaration of a deceased person shall be excluded as evidence on the ground of its being hearsay if it appears to the satisfaction of the judge to have been made in good faith before the beginning of the suit and upon the personal knowledge of the declarant." Interestingly enough, Thayer derived his idea from a remark by Mellish, L.J., in the famous English will case of *Sugden* v. *Lord St. Leonards.* Massachusetts judges and lawyers have tested this simplification of hearsay exceptions, and are generally satisfied with it. The neighbouring State of Rhode Island adopted the act with slight verbal revision in 1927.

Parol Evidence Rule and Interpretation.—The doctrines forbidding variation of dispositive documents by prior or contemporaneous agreements excluded therefrom, and limiting employment of extrinsic evidence to aid interpretation, are not, strictly speaking, part of the law of evidence. But they are usually treated in connection therewith, and it is proper to note that Prof. Samuel Williston's restatement of the law of contracts for the American Law Institute will cover both these doctrines.

Special Tribunals.—Before such tribunals as workmen's compensation boards, juvenile courts, etc., there is a tendency to relax rules of evidence.

Psychological Studies.—For years psychologists have tried to find surer methods of getting at legally contested facts; the response reaction tests of Prof. Hugo Münsterberg and Dr. W. M. Marston's blood pressure tests for perjury are among their better-known proposals. In the United States a marked amount of

experiment along such lines is now being conducted. This seems to bear more directly upon the weight to be accorded evidence than upon admissibility of evidence under technical legal rules. Yet many of these rules seek justification in the idea that the evidence or witnesses excluded by them fall into classes of low general credibility; and supposed conditions of special credibility are invoked to justify exceptions to such rules. Hence law teachers and psychologists are working in teams at Yale and Columbia universities to ascertain whether these fundamental classifications and sub-classifications should be accepted as sound. This work has barely begun, but such application of scientific method may ultimately lead to important results.

The topic just touched upon indicates a very real difficulty in bettering rules of evidence. Psychology sounds academic and unlawyer-like. Practical criticism by Wigmore, a law teacher, broke down Münsterberg's early proposals. The law teacher in turn is deemed an unworldly adviser by the active American lawyer. Justification for such distrust must be removed, and the feeling itself allayed, if harmonious progress is to be made. The American Law Institute shrewdly provides for participation by every branch of the profession in the composition of its restatements. When the Legal Research Committee of the Commonwealth Fund put a special committee under the chairmanship of Prof. E. M. Morgan to work on problems of evidence, this special committee spent nearly five years upon detailed enquiry into opinions held by hundreds of lawyers and judges. In the end it unanimously recommended five important revisions of evidential rules. Significantly and encouragingly, the States of New York and Rhode Island have already adopted one of the recommendations. On the whole, there is reason to hope that wise persistence will cause steady, if slow, rationalization and improvement of judicial proof in the United States.

EVIL EYE. The belief that certain persons can injure and even kill with a glance, has been and is still very widely spread. The power was often supposed to be involuntary (*cf.* Deuteronomy xxviii. 54); and a story is told of a Slav who, afflicted with the evil eye, at last blinded himself in order that he might not be the means of injuring his children (Woyciki, *Polish Folklore*, trans. by Lewenstein, p. 25). In Rome the "evil eye" was well recognized and special laws were enacted against injury to crops by incantation, excantation or fascination. The power was styled *βασκανία* by the Greeks and *fascinatio* by the Latins. Children and young animals of all kinds were thought to be specially susceptible. Charms were worn against the evil eye both by man and beast, and were of three classes: (1) those the intention of which was to attract the malignant glance on to themselves; (2) charms hidden in the bosom of the dress; (3) written words from sacred writings. Of these three types the first was most numerous. They were often of a grossly obscene nature. They were also made in the form of frogs, beetles and so on. Spitting was among the Greeks and Romans a most common antidote to the poison of the evil eye. Gestures, too, often intentionally obscene, were regarded as prophylactics on meeting the dreaded individual. The evil eye was believed to have its impulse in envy, and thus it was unlucky to have any of your possessions praised. It was, therefore, necessary to use some protective or prophylactic phrase such as—Unberufen, absit omen, As God will or God bless it.

The powers of the evil eye seem indeed to have been most feared by the prosperous. Its powers are often quoted as almost limitless. The modern Turks and Arabs think that their horses and camels are subject to the evil eye. Among the Neapolitans the *jettatore*, as the owner of the evil eye is called, is so feared that at his approach a street will clear: everybody will rush into doorways or up alleys to avoid the dreaded glance. The evil eye is still much feared for horses in India, China, Turkey, Greece and almost everywhere where horses are found. In India the belief is universal. Modern Egyptian mothers thus account for the sickly appearance of their babies. In Turkey passages from the Koran are painted on the outside of houses to save the inmates, and texts as amulets are worn upon the person, or hung upon camels and horses by Arabs, Abyssinians and other peoples. One of the most striking facts about superstitions in the New World is that the evil eye seems to be foreign to the whole hemisphere. Its absence is often cited as a good example of the occurrence of unexpected human divergences.

EVIRATO: *see* CASTRATO.

EVOLUTION, in arithmetic is the operation of finding a root of a number. The Greeks found the square root of a number by a method similar to the one given in elementary arithmetic and algebra books, and this passed on to or was independently developed by the Hindus. The latter gave rules for the cube root. Higher roots attracted the attention of various writers of the 16th century, the method being based upon the expansion of a binomial. (*See* BINOMIAL THEOREM.) The word "root," the Latin *radix*, is due to mediaeval translations from the Arabic, whence came the idea of "extracting the root," and so Recorde (*fl.* 1542) speaks of "pulling out" a root. The symbol for root is $\sqrt{\ }$, as in $\sqrt{2}$. For roots beyond the square root the *index* is written, as in $\sqrt[3]{5}$ and $\sqrt[4]{9}$. The symbol denotes the *principal root*. Every number has n nth roots, only one of which is indicated by the symbol $\sqrt[n]{\ }$. For example, the three cube roots of 1 are 1, $-\frac{1}{2}+\frac{1}{2}\sqrt{-3}$, and $-\frac{1}{2}-\frac{1}{2}\sqrt{-3}$, but the principal cube root is 1.

EVOLUTION, ORGANIC. At a time when the controversy over evolution, after dying down almost to nothing, has suddenly flared up again in certain backward regions and backward circles, it may be as well to state the main problems briefly and concisely before embarking on a detailed discussion.

The first point to realize is that there is really not one problem, but three problems. There is first the problem of the *fact* of evolution: has evolution occurred or has it not? Secondly, there is the problem of the *method* of evolution: if evolution has occurred, what is the machinery by which it works? And thirdly, there is the problem of the *result* of evolution: again granting that evolution has occurred, can we discover any general rules to describe the course it has pursued, or find any main trends in the process?

The third is really the affair of general or philosophical biology and does not especially concern us here. Suffice it to say that there undoubtedly exist certain general evolutionary tendencies, such as that towards increased specialization, with consequent divergence and multiplication of types. Further, that there does

exist a main trend in evolution, which consists in raising the upper level attained by life in regard to various qualities making for greater control over and independence of the environment; this main trend is generally called biological progress.

But the other two problems are of immediate concern, and it is essential to keep them distinct if the issue is to remain clear. Unfortunately, this is precisely what has usually not been done by many anti-evolutionists. They find a weak spot in some widely held theory as to the method of evolution, and at once proceed to state that the whole idea of evolution is false—a procedure only to be explained as the result of weakness of logic or of intellectual conscience.

It is obviously a good deal simpler to be sure that some process exists and is a fact than to understand precisely how it works and what its underlying machinery may be; and we need not deny the fact because we have not discovered the machinery. As an obvious example, we are very far from understanding the physiological and chemical machinery of development, by which for instance a hen arises from an egg; but that does not cause us to deny the fact that hens do develop from eggs.

It is the same with evolution. Although we know a good deal more about the method of evolution than did Darwin or any of his immediate successors, we are still in doubt as to a great many points. But we are not in the least doubt as to the fact of evolution. Among those who have gone into the evidence, that is to say among competent biologists and geologists, there is not a single one who is not convinced that evolution has occurred and is occurring.

The evidence by now is overwhelming. Details will be given in the body of the article. Here it must suffice to enumerate the main lines. There is the evidence from fossils, which is now in many cases so full and detailed as to constitute complete proof in itself. It is however supported by many other lines drawn from different fields. There is the evidence from vestigial ("rudimentary") organs, which are of no direct use to their possessors, but useful in other animals of the same general construction. It is impossible to account for these on any theory of special creation, but their existence is to be expected on the theory of evolution. The facts of embryology (*q.v.*) afford similar evidence; so do the facts concerning the common plan which is found to underlie the structure of whole groups of animals. The facts of geographical distribution (*see* ZOOLOGICAL REGIONS) are easy to explain on evolutionary principles, difficult or impossible on any other view that has so far been put forward. So are the facts concerning variation both in domestic animals and in nature, and especially the total impossibility of drawing any sharp line between individual variations, local races, sub-species and species (*q.v.*); and further the continuity of life through the generations tells in favour of evolution.

Finally there is the pragmatic value of the evolution theory. The biologist in studying living things, finds that the idea of evolution works and helps him to interpret his facts and to discover new facts and principles; while no other theory so far put forward helps him at all. The idea of evolution is as important a biological tool as, for instance, the microscope.

When we come to the method of evolution, matters are very different, and no final conclusion can be reached until a great deal more experimental and observational work has been done. Details of the main rival theories, will be considered later. Here it will be useful to point out that all such theories must fall into one of four categories (or a combination of two or more of these). First we may suppose that the environment has a direct moulding effect upon the race and racial history; this view is the basis of most Lamarckian theories. Secondly, the environment may have no effect, direct or indirect, evolution occurring as the result of changes which take place in the hereditary constitution for reasons inherent in its own nature; evolution would then be predetermined internally. This is the basis of the more extreme theories which go by the name of orthogenesis. Thirdly, the environment may have an indirect effect, by favouring some of the changes which occur in the hereditary constitution, so helping them to be perpetuated, and frowning on others to help their extinction. This is the basis of the theory of Natural Selection. The variations to be selected may arise either completely at random, or only in certain directions; and they may be "spontaneous," due only to the inherent nature of the hereditary constitution, or they may be caused by outer agencies acting on the constitution. They must, however, be sufficiently numerous and varied for the environment to exert a sifting action upon them. Fourthly, the environment may have an indirect effect, but in a very different way—through the organism's endeavouring to adapt itself to its environment, the effort then altering its structure, and the alteration in structure being finally transmitted, in whole or in part, to subsequent generations. This is the basis of the remainder of the Lamarckian theories not covered by our first alternative. Of these theories, the first and the fourth demand the inheritance of acquired characters (*see* LAMARCKISM) as a prerequisite to their working; modern research leads us to believe that neither Lamarckian view is true.

The other two do not need the inheritance of acquired characters to be workable. In the present state of knowledge, it seems probable that the third method, of natural selection, is the main agency of evolution, though determinate variation (theory No. 2) may play some part. The most important problem before the evolutionist to-day is to discover how heritable variations originate, and to what degree they fall short of occurring at random but are limited by the nature of the hereditary constitution in which they occur.

It is often asserted by irresponsible persons that "Darwinism is dead." This is very far from being the case. In so far as Darwinism was a reasoned assertion of the fact of evolution, it is much more firmly grounded to-day than it was in Darwin's own time, and every year brings fresh evidence in its support. Only in regard to the nature of the variations which are to be selected has the theory of evolution by Natural Selection suffered any important modification; in other respects it remains unshaken.

(J. S. H.)

The idea of evolution has penetrated many other departments of thought. Anthropology and ethnology are permeated with it, and so are history and comparative religion. Modern psychology recognizes that the human mind is unintelligible without an evolutionary background. The idea of evolution has re-emphasized our kinship with the animals; it has dethroned man from his position as lord of creation; but in place of the old idea of fixity it has given us the idea of the possible advancement of the human race, and of man as the trustee of future evolutionary progress.

THE THEORY OF EVOLUTION

From the earliest times man must have speculated on the nature and origin of the multitude of living creatures, both plants and animals, which people the surface of the earth. Some have assumed that the diverse forms with their different shapes and sizes, properties and habits, were each specially created, probably to fill a particular place and serve a special purpose; others preferred to consider them as the gradually developed products of nature.

According to modern doctrine, evolution and the diversity we see around us are due to the action in the past of "natural causes," which can be observed still at work in the present. This conception has been applied to the whole cosmos including both living and non-living things; but in this article we are concerned only with the evolution of living organisms.

Although in the 18th and early 19th centuries many naturalists, notably Erasmus Darwin and Lamarck, maintained that the various forms of life have evolved from one another by some process of transformation, it was not till the middle of the last century that Charles Darwin succeeded in establishing the doctrine of organic evolution on a thoroughly scientific basis. This work of Darwin has been one of the greatest triumphs of modern science. It marks an epoch in human thought, for not only has the doctrine dominated ever since all the sciences dealing with living things, but its effect has penetrated to all regions of scientific enquiry. To secure this success every sort of opposition, religious prejudice and intellectual inertia had to be overcome, and not the least resistance was due to the concept of "species" (*q.v.*) held by naturalists themselves.

Species.—This idea of species we owe chiefly to Ray (1628–1705), who first endeavoured to define species as composed of individuals derived from common parents and possessing the same constant well-defined "specific characters." Ray's work was later extended and completed by Linnaeus (1707–78), who founded the modern system of classification and nomenclature. He grouped all known plants and animals into species, genera, families, orders and classes, insisted on the objective reality of species, and introduced the binomial system whereby each was called by a Latin specific name added to that of the genus to which it belonged. Thus man was designated (genus) *Homo* (species) *sapiens*. This was a great practical advance. Organisms could now be more easily described, classified and compared, the floras and faunas of various countries could be contrasted, living could be compared with extinct fossil forms. But the adoption of this system was attended by serious dangers. To Linnaeus and his followers the "species" became the unit of creation; it was assumed to have been separately created at the beginning and to have persisted more or less unchanged ever since. All organisms were supposed to belong to species, clear cut, definable; there could be no transition between them. Thus from a convenient practical classification arose a rigid dogma which for long held a dominant position, especially among systematists concerned with the identification and classification of animals and plants. This dogma was accepted by the world at large, and its effects have not yet entirely worn off even in learned scientific treatises. One of the most important results of Darwin's work has been the destruction once and for all of the foundations on which was built the dogma of the immutability of species, and indeed the belief in the very existence of such definite units in nature.

It is now universally held by competent biologists that all organisms, living or extinct, have arisen from remote common ancestors by a process of gradual change or evolution, and further, that living matter or "life" itself, in all probability arose from non-living matter in the first stages of this evolutionary process. The only doubt which remains concerns the exact steps in the process, and the nature and relative importance of the various factors which have contributed to it.

THE CHEMISTRY OF LIFE

Characteristics of Living Organisms.—If organic evolution has taken place, it must be living matter that has evolved. Let us, therefore, examine what living organisms are composed of, what properties they have in common, how they can be distinguished from non-living matter. An analysis shows that organisms are entirely composed of the ordinary elementary chemical substances found in their inorganic surroundings, but that these elements are built up into highly complex compounds of peculiar molecular structure, and occurring only in living organisms or in their products. These compounds may be grouped in order of complexity into three classes: carbohydrates, fats and proteins. The molecule of a carbohydrate (such as sugar, starch, cellulose, etc.) is formed entirely of the elements carbon, hydrogen and oxygen; likewise the molecule of fat which is, however, more complex in structure. Proteins are the most important of these substances, since their molecules contain nitrogen and sulphur in addition to carbon, hydrogen and oxygen. To these essential elements are added small quantities of phosphorus, iron, potassium, sodium, calcium, magnesium and chlorine. The molecules of a protein are, therefore, very large and may contain many hundreds of atoms in combination, some of which form subordinate groups within them. With every increase in size and complexity, these organic molecules acquire new and often very important properties. For just as the chemical combination of atoms of oxygen and hydrogen into molecules produces a substance, water, with new physico-chemical properties not possessed by either of its constituents, so with every advance in molecular structure will new properties emerge. Many of these new properties displayed by large and complex molecules are of the highest importance in the carrying out of the functions of life.

Living organisms feed, breathe, grow and reproduce. The most characteristic property of living matter is its capacity to undergo perpetual change, and this fundamental process going on in all living things we call metabolism. It involves a perpetual transformation of material and energy. Speaking generally, animals are continually taking in food and oxygen and giving off waste products which are got rid of by excretion. The food consists chiefly of carbohydrate fats and proteins, high compounds in which the energy used in building them up is stored as potential energy which may be freed and transformed into motion or kinetic energy when these substances are again broken down into simpler compounds. This breaking down is brought about by their oxidation or burning by means of the oxygen taken in in respiration. All material entering the organism as food and oxygen eventually leaves as waste products (carbon dioxide, water and urea), except in so far as some is retained for repair and growth. All the energy brought in is balanced by work done in the performance of the animals' various activities, and by heat given off. During the whole process of metabolism, no matter or energy is either produced or destroyed, but merely transformed. One of the most fundamental generalizations of modern biology is that the principles of conservation of matter and the conservation of energy hold good in living organisms as they do in the inorganic world.

What has been said above of metabolism in animals applies also to plants. But whereas in animals the powers of synthesis are restricted to the building up of their substance from organic materials, most plants can form carbohydrates, fats and even proteins from the simplest inorganic compounds. Thus green plants, with the help of chlorophyll, can build up starch from water and atmospheric oxygen by a synthetic process in which the energy of sunlight is absorbed, and can synthesize protein by the addition of simple salts of nitrogen derived from the soil. Many of the lowest plants (Bacteria) can build up proteins without chlorophyll from inorganic compounds, and some can use the free nitrogen of the air. Thus carnivorous animals depend on vegetable feeders, these in turn on plants for nutriment, and ultimately all living matter is derived from the non-living matter of the environment.

Now in the living organism the food does not all pass through merely as fuel; the machinery itself is involved in the process of change. The food serves to build up the complex living substance, part of which is perpetually being broken down again into non-living matter. The highest compounds are unstable, and the complete process of metabolism includes a double process of building up and breaking down. Energy is stored in the first and freed in the second. The organism has at its disposal the excess of energy set free by the oxidation of the food material over that required for the working and upkeep of the machinery. There is thus in living substance a mixture of compounds, some leading up to the highest complexity and others leading down to the waste products, and this mixture of substances undergoing these physico-chemical changes constitutes the living matter known as protoplasm, well named by T. H. Huxley, the physical basis of life. Protoplasm, the essential living substance present in all living organisms and the seat of all their activities, is a viscid colourless substance of granular appearance under the microscope, being apparently formed of minute globules suspended in a more fluid medium. Dead protoplasm can be analysed into a variety of proteins associated with mineral salts. Suspended in the protoplasm may be found granules of food material about to be used up, various products of its own activities, and waste material about to be rejected.

The most characteristic properties of living matter are irritability, growth and reproduction; they all depend on metabolic processes taking place in protoplasm. Like other physico-chemical processes, metabolism is limited by definite conditions. The essential elements, food, oxygen, water, must be present, and it can only take place within a certain range of temperature, not so high as to coagulate or destroy the proteins, or so low as to stop chemical action. Usually the metabolic processes take place with the help of certain proteins known as ferments or enzymes (*q.v.*), which hasten and facilitate chemical action. It has recently been proved that for the carrying out of many processes, special compounds called vitamins (*q.v.*) are necessary.

A living organism may be likened to a whirlpool—new non-

living matter is always being brought in from the outside, caught up and moulded into protoplasm, and passed out again at the periphery as dead matter having yielded the energy necessary for its activities. All the phenomena of life on which these activities are based are strictly determined and limited by external conditions on the one hand, and the properties of the materials taking part on the other. Protoplasm is not one particular chemical compound, but a mixture of substances; some are materials about to be built up, others the products of their decomposition. This life process forms a chain of interdependent actions, every link of which is essential, and the full attributes of life are displayed only by the whole series of substances and their interactions in the process. No single link by itself can be said to be living; no hard-and-fast line can be drawn between the living and the non-living. There is no special living chemical substance, no special vital element differing from dead matter, and no special vital force can be found at work. Every step in the process is determined by that which preceded it and determines that which follows.

That universal property of living organisms known as irritability, or the power of responding to a stimulus, brings them into relation with their environment, and depends on the fact that protoplasm is in a state of unstable equilibrium which can be disturbed by changes in the surrounding conditions. Neither the amount nor the character of the response, *i.e.*, the resulting change in metabolism, is directly related to that of the stimulus, but both are determined by the structure of the mechanism stimulated and the amount of energy stored in it. Thus, just as the pressure of a button may cause a bell to ring or an engine to start, so a given stimulus may cause a plant to grow or an animal to move. But there is an internal environment as well as an external environment, for the various parts of an organism may react on each other. One organ may stimulate another and so regulate its action, as does, for instance, the governor of a steam engine. Thus may arise a series of co-ordinated responses started by a single external stimulus. A special organ for securing this result is seen in the nervous system of animals; but in all organisms the various parts are closely interdependent, and special substances, hormones (*q.v.*), may be secreted by one organ to regulate the action of another. This integration of parts is one of the most striking characteristics of living organisms, and becomes more and more perfected in the higher forms.

A living organism, then, from the point of view of the scientific observer, is a self-regulating, self-repairing, physico-chemical complex mechanism. What, from this point of view, we call "life" is the sum of its physico-chemical processes, forming a continuous interdependent series without break, and without the interference of any mysterious extraneous force. It is true that we are still far from being able to give a complete scientific explanation of all the processes involved, but their analysis is pushed further every day, and there is no good reason to believe they are not all capable of such explanation.

First Steps in Evolution.—Although we are ignorant of the origin of life, we may suggest what may have been the first steps in its evolution. It used to be thought that simple organisms, such as the Bacteria of putrefaction and fermentation moulds, Infusoria and even small worms, arose spontaneously *de novo* in liquids containing dead organic matter (theory of abiogenesis [*q.v.*]). But Pasteur and others in the last century definitely proved that such creatures arise only from living germs or spores already present in the liquids, and that no organisms of any kind will appear and no putrefaction take place in substances in which the germs have been killed and from which new germs have been rigidly excluded. The important principle of biogenesis (*q.v.*) was thus established, according to which all living organisms are derived from pre-existing living organisms without break. It is one of the chief foundation stones of the modern doctrine of organic evolution.

But although this principle of continuity applies to all organisms at the present day, which have a long history behind them and have no doubt departed greatly from the initial stages in the evolution of living matter, there must have been a time when protoplasm first appeared. It must be supposed that long ago, when conditions became favourable, relatively high compounds of various kinds were formed. Many of these would be quite unstable, breaking down almost as soon as formed; others might be stable and merely persist. But still others might tend to reform, to assimilate, as fast as they broke down. Once started on this track such a growing compound or mixture would inevitably tend to perpetuate itself, and might combine with or feed on others less complex than itself. These first steps in the elaboration of living matter probably occurred in the sea, for protoplasm contains the same salts as sea-water and in much the same proportions.

UNITS OF LIFE

Cells.—Protoplasm is necessarily a constituent of every living creature, but the organism is not entirely made up of it, and much of its bulk may be composed of substances about to be built up into protoplasm or of the accumulated dead products of its past activity, such as the woody tissue of a tree, the hard substance of bone, the skeleton of a coral. Only that part of an organism is truly alive which is protoplasmic, and the protoplasm normally exists in the form of "cells." The cell is a small, usually microscopic, mass of protoplasm, consisting of a nucleus and surrounding cell-body. It is generally enclosed in a cell-wall formed of its own secretion. Plants and animals are made up of such cells either singly or in aggregates. Growth is due to the increase in size and multiplication of the cells. They do not grow indefinitely, but each, having reached a certain bulk, divides into two daughter-cells. All the cells composing the body of an individual are thus derived by repeated binary fission from a single original cell. Cells may become differentiated and may acquire parts adapted for performing various functions. Differentiation in multicellular forms is related to the progressive division of labour among the cells, comparable to the division of labour among the individuals of a community, and is accompanied by specialization for the performance of special functions. The body of a multicellular plant or animal is thus an aggregation, not of separate units brought together, but of a multitude of related cells remaining in association and building up its tissues. As a rule the tissue-cells remain in actual protoplasmic continuity by slender connecting bridges; but in animals, certain cells may become free, as, for instance, the white corpuscles of the blood. The activity of an organism is the sum of the activities of its component cells. It is probably to enable oxygen and food to reach all parts, and waste substances to escape, that the protoplasm is thus subdivided into small masses. Moreover, there is interchange of material between nucleus and cell-body, and the relative size of the two must be kept within certain limits. The contents of the nucleus (nucleoplasm) and those of the cell-body (cytoplasm) differ considerably from each other.

Both body and nucleus are necessary for the life of a cell; one cannot live without the other. If a cell is divided into halves, only that with the nucleus will continue to live, grow and reproduce. Among true plants and animals such a cell is the smallest unit of life. But in the Bacteria, doubtfully classified as plants, there is no well-defined nucleus, the chromatin being scattered. Possibly they are the surviving representatives of a primitive stage before the typical cell structure was differentiated.

In the lowest plants, Protophyta, and the lowest animals, Protozoa (*q.v.*), the individual generally consists of a single cell, capable of performing all the functions of life and consequently often provided with highly differentiated cell-organs. Such a unicellular individual may assimilate, grow, reproduce, move and regenerate lost parts. But in the multicellular plants, Metaphyta, and multicellular animals, Metazoa, as differentiation advances, the various cells may become specialized to perform certain functions, and correspondingly unable to carry out others. More especially in animals do cells become so specialized (to form nutritive, nervous, muscular, excretory, skeletal and other tissues) that they can no longer continue to live except in association with each other, supplying each other's wants. They tend to lose the power of reproduction and usually are only capable of giving rise by division to cells like unto themselves.

A unicellular organism does not increase indefinitely in bulk; when it exceeds the size normal for the full-grown individual of

the species, it tends to divide into two. The nucleus divides first, then the cell-body; the resulting two daughter-cells, each with its own nucleus, then separate and grow into adults similar to the original parent. It is the same with the cells of higher organisms. Each multicellular plant or animal starts as a single cell rich in unspecialized protoplasm, which grows and divides repeatedly, and at every division half of the nucleus passes into each daughter-cell. But here, instead of the cells separating, they remain closely associated as parts of a single complex individual. Thus every cell is derived from a pre-existing cell, and every nucleus from a pre-existing nucleus.

Mitosis.—The behaviour of the nucleus and of the chromatin during cell-division is so important with regard to heredity and evolution that it must be described in further detail. It is the nucleus that initiates the division which takes place by a remarkable process known as karyokinesis or mitosis (*see* CYTOLOGY). In the resting stage the chromatin is dispersed within the nuclear membrane in the form of granules or an irregular network. At the start of mitosis the chromatin gathers into coiled threads which break up into definite pieces—the chromosomes. Each chromosome soon splits longitudinally into two equal halves. Meanwhile, from a small mass of denser protoplasm situated close to the nucleus and known as the "central body" or "division centre" (often containing a central granule or centrosome), generally arise delicate radiating fibres (aster). By the division of this body are formed two "division centres" which move apart to the opposite poles of the nucleus, while a central spindle of fibres develops between them. The nuclear membrane having by this time disappeared, the chromosomes become arranged in a ring round the equator of the spindle. The two halves of each chromosome now separate and travel to the opposite poles of the spindle. There they again form coiled threads and break up into granules, the systems of fibres disappear, the nuclear membranes are restored, and thus two new nuclei are reconstituted similar to that of the parent-cell. Division of the cell-body then yields two nucleated daughter-cells. It is very important to notice the continuity of substance during this process. Cytoplasm, nucleoplasm, central bodies and chromatin are all parcelled out to the daughter-cells. Above all, each daughter-nucleus receives the same number of chromosomes, and apparently exactly the same amount of chromatin.

Apart from some exceptional cases, and certain differences in detail, the process of normal cell-division and mitosis is essentially the same in all plants and animals. The same number of chromosomes appear at every division, hence every nucleus in the body of a multicellular organism contains the same number (except the germ-cells as explained below). Moreover, the number of chromosomes may differ widely even among allied forms, but is normally constant within each species.

CONTINUITY AND PERPETUATION

Sexual Reproduction.—If organisms did not reproduce and multiply, they would sooner or later be extinguished, if not by natural, at all events by accidental death. For this purpose they must separate off some portion of their body capable of growing into a new individual. This gives rise to some method of vegetative or asexual reproduction, or to sexual reproduction. We have already seen that unicellular organism can multiply by mere fission into two; similarly in the simpler multicellular plants, such as the fresh-water alga *Vaucheria* or the fungus *Mucor*, every cell is capable of growing into a new plant. But in many forms special reproductive cells (spores) or multicellular bodies (gemmules and buds) are set apart for the purpose, often in vast numbers. Propagation by shoots developed on runners or tubers is common among the higher plants, and a very similar method of bud-formation is widely distributed among animals such as sponges, polyps and sea-squirts. In the Bacteria, indeed, fission and spore-formation seems to be the only method of multiplication; but in all other groups of plants and animals, sexual reproduction occurs, though the asexual method may also be retained.

The typical sexual reproduction of plants and animals takes place by special cells of two kinds set apart and liberated for the purpose, and called the reproductive cells, germ-cells or gametes. Each gamete of one kind gives rise by fusion with a gamete of the other kind in the process of fertilization, to a single cell, the zygote, which grows into a new individual. Usually the two kinds of cell become differentiated along divergent lines adapted to the functions they have to perform. One, the ovum, is quiescent, large, stored with food-material for the nutrition of the developing embryo to which it will give rise. The other, the spermatozoon of animals or spermatozoid of plants, is small, motile, and usually furnished with a head containing the nuclear material, and a vibratile flagellum or whip-like "tail," with the help of which it swims towards and bores its way into the ovum. An individual bearing ova is of the female sex (♀); one bearing spermatozoa is of the male sex (♂). But the terms male and female are often conveniently extended to the gametes themselves. Hermaphrodites give rise to both kinds of germ-cells.

In fertilization one male gamete fuses with one female gamete; and not only do their cell-bodies unite, but their nuclei also combine into one nucleus. Thus the nucleus of the resulting zygote contains chromatin derived from two individuals, since the gametes usually come from different parents; for it is only exceptionally that hermaphrodites are self-fertilizing. Unsuccessful male gametes, which do not reach an ovum, perish; and likewise unfertilized ova die, except in those rare cases where parthenogenesis (*q.v.*) occurs (among lower plants, insects, etc.).

The significance of fertilization is great: on the one hand it provides a stimulus to the ovum for renewed activity and development, on the other it combines two streams of hereditary substance.

The evolutionary history of sex (*q.v.*) is not yet known. Among unicellular forms sexual reproduction may be of a much simpler kind than that described above. For instance the gametes of the two sexes may differ little or not at all from each other, and among unicellular forms two ordinary individuals may act as gametes coming together and fusing to form a zygote. These simpler modes of fertilization may not represent actual stages in the evolution of sex, but give some notion of how sexual reproduction may have developed. Since typical fertilization occurs among both plants and animals it is probably a very ancient process, already fully developed in the common ancestors of all these organisms. It may have originated at a remote time in the history of protoplasm, when it was possibly beneficial for two masses of living material of slightly different constitution to mix and combine their properties.

Among the lowest multicellular plants, the Algae, there are forms in which every cell, or almost every cell can act as a gamete or give rise to gametes, and so share in the making of a new generation. But there is an increasing tendency among higher plants, and especially in animals, to restrict the reproductive function to certain cells, which may be set apart at a very early stage in the embryo and often become localized in special organs or gonads. Thus arises a distinction between germ-cells, destined to give rise to gametes, and body or somatic cells devoted to vegetative functions. On such facts is based Weismann's theory of the continuity of the germ-plasm, the most valuable conclusion of which is that germ-plasm, that substance which is passed on from generation to generation by the gametes, can be traced back through an unbroken lineage of relatively undifferentiated cells to the original zygote, and to a certain limited extent can be said to be independent of the body or soma which harbours it. Whereas the rest of the multicellular organism, the soma, undergoes differentiation and eventually dies, the germ-cells continue for ever giving rise to new generations. Such considerations bring us to the subject of the origin and biological significance of death.

Death.—The question arises whether natural death, as distinct from death due to accident or disease, is an essential and inevitable attribute of life; whether all living creatures necessarily grow old and die. Certainly the living mechanism must wear out, and downward changes must take place in the course of metabolism; but so long as these are sufficiently compensated and repaired they need not lead to death. The Bacteria and unicellular

organisms which can multiply by simple fission may go on doing so indefinitely so long as environmental conditions are favourable. The individual may be said to disappear in the splitting, but it divides into two living individuals—there is no corpse. Such organisms may become weakened and eventually killed by the accumulation of their own waste products; there appears to be no reason, however, why growth and division should ever cease provided the conditions remain favourable, waste products are removed, and a sufficiency of food-material and oxygen is supplied.

Natural death, then, does not necessarily occur among unicellular organisms if the essential mechanism of life, and more especially the nucleus, is continuously or periodically repaired. They are potentially immortal, and the same may be said of the germ-cells of higher forms. Death appears among living organisms when the soma becomes differentiated from the germ-cells. The soma dies, but the germ-cells continue to live and multiply, transmitted from one mortal parent to the next. But why, it may be asked, should the soma die? Even the soma might conceivably go on living for ever provided the conditions were favourable and the wear and tear of life continually repaired. That somatic cells are capable of indefinite growth and multiplication seems proved by recent experiments on their artificial culture. Fragments of animal tissues have been kept alive for countless cell-generations by periodic transplantation to fresh nutritive medium (*see* TISSUE CULTURE) and it is well known that plants can be propagated indefinitely from cuttings. But it is one of the penalties of specialization that organisms in adaptation to particular modes of life tend to acquire a definite, suitable shape and size. However well-regulated they may be, those essential proportions between surface and volume can hardly be so well preserved, that nice co-ordination of parts, that power of repairing waste and injuries, can hardly be so accurately adjusted as to continue working smoothly for ever. To reach the condition of sexual maturity, to preserve the life of the individual long enough to ensure reproduction, is all that is essential for the continuance of the race. And so we find that the length of life of an organism becomes adapted to its needs, and the energies of the individual are exhausted in securing the success in life of the next generation. For instance, many animals in the colder regions live only for one season, leaving behind them their eggs to survive the winter and develop next year. Frequently the male sex dies as soon as fertilization has been accomplished. A definite relation can be traced between the length of life of the individuals of a species, the number of young produced and the care required to bring them up. Thus the longevity of an organism is bound up in evolution with its method and rate of reproduction.

If we have insisted in the foregoing paragraphs that living organisms are the products of a continuous uninterrupted stream of ever-changing and ever-growing substance, that every organism is derived from a pre-existing organism, every cell from a pre-existing cell, every nucleus from a pre-existing nucleus, and indeed, all chromatin from pre-existing chromatin, it is because this principle of continuity is the very foundation rock on which is built the modern doctrine of organic evolution.

As a matter of history it was not this principle which led, in the last century, to the widespread acceptance of the evolutionary interpretation; at that time, indeed, most of the evidence for it had not yet been discovered. Rather was it the cumulative, but indirect, evidence derived from the study of the classification, comparative anatomy, embryology, geographical distribution and palaeontology of animals and plants, as well as from the study of variation and heredity, subjects then first coming into prominence.

THE DARWINIAN THEORY

Darwin.—Previous to Darwin those naturalists who advocated the theory of transformation laid stress sometimes on the cumulative effects of external conditions, sometimes on the action of assumed internal factors, and at other times on the guiding influence of more mysterious perfecting principles. All such speculations failed to convince, being either obviously inadequate, or calling in evolutionary forces of which no scientific explanation could be given and the existence of which could not be proved. Lamarck insisted on the direct effect of environment as the main cause of evolution in plants, but to account for that of animals brought in other factors such as their direct response to new needs and new habits. He conceived that efforts, habits, use and disuse of organs induced changes in the individual which could be inherited by the progeny and so lead to transformation and evolution. But his theories were not worked out in scientific detail, involved many assumptions and some contradictions, and failed to carry conviction (*see* LAMARCKISM).

It was Charles Darwin who, by the patient collection of a vast array of significant facts concerning all sorts of organisms, living and extinct, first clearly showed in his immortal work *The Origin of Species* (1859) how overwhelming is the evidence that evolution has really taken place, and how impossible it is to account for the facts on any other hypothesis. But his great merit is to have made it clear that evolution may be accounted for as the result of "natural causes," which can be seen at work at the present time, can be tested by observation and experiment, and leave no room for any mysterious governing causes or interfering forces in addition.

Darwin and Wallace simultaneously discovered the great principle of natural selection, the keystone to the Darwinian explanation of the method of organic evolution, which may be described in Spencer's phrase: the survival of the fittest in the struggle for existence. It was shown that organisms vary, that these variations may be inherited, that—in competition with others—those which vary in an advantageous direction are most likely to survive and to leave progeny behind them, and that this must inevitably lead to a cumulation of variations and evolutionary change. According to Darwin, then, the chief factors which contribute to the process of evolution are variation, heredity and the struggle for existence. To their combined action he gave the name "natural selection" (*q.v.*) in analogy with the similar process of artificial selection carried out by man on domestic plants and animals. For the breeder, by continually selecting and breeding from those individuals which varied in directions favourable to his purpose and fancy, has been able to transform their characters (bodily and mental) and so bring into being various races differing from each other and from the parent stock even more than do species in nature.

While the validity of the theory of natural selection cannot be denied, its importance and that of the different factors contributing to it in the general process of evolution have been and still are variously estimated. These factors may now be examined in more detail.

VARIATION

Variation from the mean is universal; no two individuals are exactly alike in every detail however closely they may be related. Parents and offspring, brothers and sisters differ from each other, and the differences are called variations. The characters of organisms are all those qualities and properties whereby we can describe them and distinguish them from each other, such as shape, size, colour, mental capacities and so on, and all these are variable. Variation, in fact, affects every sort of character, structural or functional; and occurs at every stage of life. If these variations are measured and arranged in order of size, from the smallest to the largest, it is found that the medium measurements are the most frequent and that measurements became rarer and rarer towards the two extremes. In other words, out of a number of individuals closely related or belonging to the same species, the majority approach the mean, and the more they deviate from the mean the rarer they are (*see* VARIATION, BIOMETRY).

Coming now to the cause of these variations, we find that they are really of two kinds and due to different causes; but to understand the nature of variability we must analyse it further in the light of heredity. When a character of the parent reappears in the offspring it is said to be inherited. There is, of course, a physical basis, a mechanistic aspect of heredity as of the other phenomena of life. The reason why like gives rise to like, why the reproductive cells of, say, a snail, a fly and a fish, all developing under the

same conditions in the same pond, reproduce the same bodily structure, the same functional capacities, the same psychological powers, the same complex individuality as their respective parents, is because they are each composed of the same protoplasm as their parents. Therefore, under approximately similar conditions of environment, they are bound to develop into approximately similar organisms. This special protoplasm, peculiar to the particular organism concerned, is transmitted by the reproductive cells; there is a direct continuity of substance, and only thus can the characters of one generation be made to reappear in the next. Hence the fundamental importance of the principle of continuity insisted upon in previous paragraphs.

We may distinguish, then, two sets of factors contributing to the formation of every organism: on the one hand the substances (germ-plasm) actually transmitted, on the other hand the factors of the environment or conditions under which it develops. The former may be called factors of inheritance. Every organism and every part of it is the result of the interaction of the factors of inheritance, and the conditions or stimuli which influence its metabolism and hence its differentiation, growth, behaviour. Every character is thus of the nature of a response to stimulus, and the characters of an organism are the sum of its past responses. Factors of inheritance are transmitted; characters, however, are not transmitted as such, but are inherited, formed anew in every generation. It is important to realize this distinction. Clearly, if both the conditions and the factors of inheritance remain the same there will be no variation and, consequently, no evolution. Variation, *i.e.*, deviation from the parental form, must be due to some change, either in the factors, or in the conditions, or in both.

It is a matter of common observation that individual organisms are to some extent modified by altering environmental conditions, becoming changed when transferred from one environment to another, by the application of new stimuli, by use and disuse. Plants offer obvious examples of such effects, and often come to vary markedly from each other owing to differences of light, temperature, moisture or the composition of the soil. The same species, even the same individual, may take on a different aspect if cultivated in the garden or grown in the open. Animals are likewise modified and caused to vary in structure or behaviour; but usually to a less extent, especially the more elaborately organized higher forms. For in these the metabolic processes are to a greater extent regulated by the internal environment, so that the effective stimuli are more constant and less easily altered. Yet they are no exceptions to the rule, and there are many examples among animals where conspicuous differences are induced by changes in the environment. This plasticity or modifiability, this power of responding in different ways to stimuli of various kinds, or of varying intensity, is a property of all living organisms and a cause of variation.

Now, Lamarck and the older writers assumed that such acquired modifications can be transmitted in some way from parent to offspring, that they tend to increase from generation to generation by a process of cumulation which leads to the transformation of organisms and to their evolution. Such an assumption is not justified. As Weismann first showed, there is no proof that modifications are transmitted, and no good reason to believe that they are cumulative.

An artificial distinction is often drawn between characters, some of which are said to be "acquired" as the result of the direct action of conditions, and others said to be "innate." But since all characters, as explained above, are the result of the interaction of the transmitted factors of inheritance, with the environmental stimuli encountered, this distinction cannot hold good.

It may be concluded that the reason why two organisms resemble each other is because they start with the same complex of germinal factors of inheritance and develop under the same environmental conditions. Hence, if either the factors or the conditions are altered, variation will result. What may be called the normal bodily and mental structure is that which develops under the usual complex of environmental stimuli. When some deviation occurs and this variation is due to a change in conditions, it may be called a *modification;* when it is due to an alteration in the factors of inheritance it may be called a *mutation.* Thus, although there is only one kind of character, there are two causes of variation. Both may give rise to new characters which may be inherited and reappear in following generations. The mutation will necessarily reappear if the environment remains unchanged, since the factors of inheritance are actually transmitted. So will the modification reappear, although not transmitted, if the conditions which called it forth persist, if the necessary stimuli are present; but it will not reappear if these stimuli are absent. It follows that a new mutation will be inherited in a constant environment, but that the inheritance of a new modification depends on the presence of the necessary conditions. The point of prime importance to notice is that mutations, being due to lasting alterations of the factors of inheritance, will be persistently inherited; and by the addition of new mutations may lead to evolution.

To avoid ambiguities, many authors now use the terminology of Johannsen: the material factor of inheritance is called a *gene;* the word *genotype* is used to signify the whole complex of genes possessed by an organism, and the word *phenotype* to denote the form derived from it, the sum of its characters. The phenotype is moulded by the environment; different environments will give rise to different phenotypes. The more plastic or modifiable the genotype, the greater will be the number of possible phenotypes and the greater the difference between them. Genotypes are transmitted, phenotypes are (may be) reproduced.

HEREDITY

Genetics.—The subject of heredity (*q.v.*) and the details of its mechanism are dealt with in another article, but some account must be given here of the chief results of the modern science of genetics, founded by G. Mendel, in so far as they help us to understand evolution.

In sexual reproduction the specific substance containing the essential factors of inheritance must be transmitted in the germ-cells, and it has now been shown that it is present in their chromosomes, and is carried by the gametes of both sexes, since inheritance is equal from both parents.

If two individuals of a species differing from each other by some contrasting character, say a white-flowered or a red-flowered snapdragon, are crossed, their progeny will have pink flowers unlike those of either of the parents. If, now, two of these pink-flowered "hybrid" or F_1 generation, are interbred, they will produce offspring (F_2 generation) of three kinds, with white, pink and red flowers, and in the proportion of one: two: one respectively. The white-flowered individuals will breed true and continue to breed true if interbred, and similarly the red-flowered individuals; but the pink-flowered will never breed true. If the pink are interbred they will, at every generation, give rise again to the three kinds and in the same proportion. It is concluded that the appearance of the white or the red character in the phenotype is due to the presence in the zygote of either white-determining or red-determining factors transmitted from the parents; and that the appearance of the pink character is due to the presence of both a white- and red-determining factor in the same zygote. Further, it is concluded that the factors in a zygote are in pairs, one received from the paternal and one from the maternal parent, that in the formation of gametes only one kind of each of the pair of contrasting or alternative factors can pass into each gamete, and that, therefore, the factors are *segregated* and so distributed to the individual gametes. The zygote or individual bearing the pair of similar factors is called a homozygote, that bearing the pair of dissimilar factors is called a heterozygote. That the above conclusion is correct may be verified by "back-crossing" a heterozygote with a homozygote, when the resulting offspring will consist of homozygotes and heterozygotes in equal numbers. Frequently the heterozygote resembles one or other of the parents more or less completely; for instance, all the F_1 offspring of a cross between a black and a white (albino) mouse will be black. In such cases that factor of the pair which is expressed in development so as to mask the effect of the other, is said to be dominant, and that factor whose effect is masked or prevented is said to be recessive. A mouse homozygotic with regard to factors determining black-

ness is a pure dominant, one homozygotic with regard to factors producing whiteness is a pure recessive.

The Chromosome Hypothesis.—Cytology (*q.v.*) has revealed the mechanism for the segregation and distribution of these factors or genes. It was stated above that the number of chromosomes is constant in a species and reappears at each divison of the nucleus. There is evidence that the genes are arranged in a linear series, so that at each division, when the chromosomes split longitudinally, every gene is divided and each daughter-chromosome receives a complete set of genes similar to that of the parent-chromosome. However numerous the cell-divisions, therefore, the resulting nuclei remain the same as regards the factors of inheritance contained in them. Now it is clear that when two gametes join in fertilization the zygote so formed would contain double the parental number of chromosomes, were not some device adopted for reducing them. This is brought about in the history of the germ-cells by a "reduction division" of the nucleus in the course of which the chromosomes, instead of splitting into two, combine in pairs and then at division merely separate again to be made up into the two daughter-nuclei. Thus each of the resulting nuclei has only half the usual number of chromosomes found in the ordinary somatic cells. On fertilization this full number is restored. The total inheritance received by an organism is the sum of the factors transmitted to it from its parents by their gametes. The factors or genes are independent units capable of growth and multiplication; are stable, separable, capable of being independently transmitted, segregated in the gametes, and recombined in the zygotes. They preserve their identity and properties when entering or leaving combinations with other genes. They form essential links in the metabolic cycle of the organism, and so influence and direct its development, interacting with environmental conditions in such a way as to give rise to corresponding characters. The genes may reinforce or hinder each other's actions. A single gene may visibly affect all or some of the characters, and the presence of several if not all of the genes may be necessary for the full development of a single organ or part.

It follows that an organism can only exhibit those characters for the development of which it has the necessary genes. The presence of dominant genes may be inferred from its characters; however, since some genes may be recessive, the total factorial equipment of an organism cannot be told from its characters alone, but only by the results of breeding which will bring out the recessive characters in the "recessive" homozygote individuals.

It follows also that any mutational alteration of factors will necessarily be transmitted and perpetuated unaltered, unless some fresh mutation supervenes; and that the factors are not altered, nor their effects necessarily swamped or diluted by intercrossing, however prolonged. Two important conclusions affecting the general theory of organic evolution follow. In the first place it is the character, not the genes, that are directly selected in natural as in artificial selection. The suitable phenotype is successful in the struggle for existence, and the genes are only indirectly selected in so far as they correspond to it. Secondly, the modifiability of an organism is necessarily strictly limited by the potentialities of its complex of genes. It may become modified in various directions, since various environmental conditions may call forth a response, and this may vary in amount according to the strength and duration of the stimulus. Once the maximum response has been reached, however, it cannot go further. Since modifications are not cumulative, it is the mutational variations, due to some alteration in the complex of genes, that are important in enabling evolutionary transformation to take place. By the cumulation of factorial changes the lasting and presumably unlimited alteration of characters can be brought about.

Origin of Mutations.—Evolution may be said to be based on inheritable mutations; hence the supreme importance of ascertaining, if possible, what gives rise to them. They are sometimes stated to arise spontaneously, which is a way of saying that we do not yet know what causes them to appear. It must be confessed that little advance has been made towards the solution of this problem since the time of Darwin. Yet something has been ascertained by careful observation and experiment. Mutations may affect any or all of the characters; they may be dominant or recessive, large or small, even scarcely perceptible; they occur rarely, but apparently more frequently in some species than in others; T. H. Morgan has discerned some 400 in his breeding experiments with the fly *Drosophila,* both in nature and in organisms under experimental conditions. The same sort of mutation may repeatedly recur, and the same sort of mutation, for instance, albinism (the absence of pigment), may occur in different organisms.

All attempts to determine the actual cause of mutational alteration of the genes, or to bring about such alterations artificially, have so far yielded inconclusive results. Tower, experimenting on the Colorado beetle (*Leptinotarsa*), claimed to have brought about true inheritable mutations in colour and pattern by submitting some beetles at a certain stage and for a certain time to extremes of temperature and dryness. Heslop Harrison has caused melanic mutations to appear in moths by feeding the larvae on leaves impregnated with certain salts of manganese. Müller has produced mutations in flies (*Drosophila*) by exposing them to X-rays. But it is to be noticed that in these cases the mutations which appear seem to be such as are already known to occur in nature, that only some of the individuals respond to the treatment and that it is not yet clear that the stimulus applied does more than hasten or facilitate the expression of some factorial difference not primarily due to it.

Mutations may, however, be due to several kinds of factorial changes and may, to some extent, be classified accordingly. For instance, since the genes are very numerous and can be segregated, sorted out and recombined in an almost infinite variety of ways, scarcely any two individuals will have exactly the same combination or factorial make-up. The individuals of a species may differ thus from each other, may be homozygotic for some factors, but heterozygotic for others. Another source of mutation is the irregular distribution of chromosomes in the germ-cells, or their duplication leading to the formation of "diploid" and "polyploid" races with new properties. Since the chromosomes of different existing organisms differ much in shape, size and number, it is clear that there has been variation in these characters in the course of evolution.

But although combinations, reshufflings and duplications of existing genes may give rise to many mutations, they can hardly account for the vast changes which have taken place in organic evolution. In a complete theory the first origin and diversity of these factors must still be accounted for. It must be supposed that new factors have been added and possibly that old ones have dropped out, that new material has entered the stream of germ-plasm, into the cycle of metabolism, and become incorporated as self-propagating ingredients joining in harmonious co-operation with previously formed factors. Presumably this building process is still going on. Mutation, and indeed evolution itself, must be based on the addition to, subtraction from, or alteration in the factors of inheritance. That the factors may be extraordinarily stable seems to be proved by the fact that many organisms have scarcely changed since the deposition of the earliest fossiliferous rocks in remote geological ages. Yet other organisms have changed rapidly and mutations generally turn up even during the short period during which animals and plants have been bred artificially. Since ordinary external stimuli seem to alter the factors but rarely, if at all, it may yet be some day shown that alterations in the genes are due to the inherent instability of certain of the atoms composing them and to the action of certain radiations pervading the environment.

STRUGGLE FOR EXISTENCE

The remorseless, ceaseless struggle for existence, that most essential factor in the process of natural selection, depends on the fact that more organisms are born into the world than can live in it. They tend to increase in geometrical ratio, and their powers of reproduction are often prodigious. A female cod-fish may lay some 9,000,000 eggs a year. The eggs of a tapeworm and other internal parasitic worms may be counted by the million. A single pair of carrion flies (*Musca carnaria*) may produce 20,000 larvae, which will hatch out into flies in about a fortnight, giving rise in turn to some 200,000,000 hungry larvae. No less prolific are

plants. It has been calculated that a single cholera bacillus would give rise to 1,600 trillions of bacilli in a day of free propagation. No doubt, such unrestricted reproduction rarely, if ever, occurs; unfavourable conditions, devouring enemies and competitors are always at hand to keep the numbers down. But all living organisms are striving to increase their numbers, to extend their range, to find new regions for expansion. There is a perpetual competition for space, food and all necessaries of life. So the fauna and flora of any region are made up of a number of diverse species, closely packed and, as it were, exerting mutual pressure. If one increases it must be at the expense of some other. In any given district a balance is soon struck, and an equilibrium established between death-rate and reproduction, in which the average number of individuals of each species remains approximately constant.

How great are the possibilities of increase, and how effective are the natural checks to reproduction, may be seen when the balance is disturbed and some of the checks temporarily removed, as, for instance, owing to a change of climate or the intervention of man. As examples may be mentioned the swarms of lemmings, and of locusts which, occasionally or periodically, sweep over vast regions; also the great epidemics of diseases. Similar expansion of one species at the expense of others is continually going on on a small scale, even in the most stable flora and fauna. The extraordinarily rapid increase of a species, introduced into a new country where it does not meet with the ordinary checks occurring in its native habitat, is seen in the case of the European sparrow in North America, the rabbit in Australia, the Phylloxera insect which almost exterminated the vines of Europe. The spread of water-cress blocking the rivers of New Zealand and of the American water-weed those of Europe, the devastating conquest of vast areas in Australia by the prickly pear, are examples from the plant world.

The intensity of the struggle varies in different seasons, sometimes periodically. In a stable population on the average only two individuals can survive to replace the parents out of the whole number of offspring. As a rule the greatest destruction takes place when the organisms are quite young.

This constant struggle for existence is the primary factor in the process of natural selection whereby adaptation is brought about. The resulting selection is between the variations which are in all possible directions, as already explained; some will be advantageous, some disadvantageous, and others perhaps neutral. The first test every organism has to pass is that of viability, the power to live at all. Just as the intensity of the struggle may be measured by the death-rate, so a variation is advantageous in so far as it lowers this rate; and this gives a measure of its "selection value." Selection acts like a sieve, separating individuals best endowed to survive from others less fortunate. It may be represented equally well as the survival of the fit, or as the elimination of the unfit. In the long run those organisms which vary in the "right" direction will succeed and leave offspring behind them, while the others will be crushed out. In so far as the advantageous variations are due to lasting factorial changes capable of being transmitted and accumulated by the piling up of fresh changes, evolution will continue in the direction of adaptation. Only thus can the adaptation of living organisms be intelligibly explained, and this is the great merit of Darwin's theory of evolution by natural selection which has secured its triumph over rival theories.

It should be clearly understood that the theory does not explain variation, but accepts its existence as affording the material for selection to work on. As Darwin insisted, without variation natural selection can do nothing. What selection alone can do is to pile up individual favourable differences so as to bring about ever-increasing divergencies along various lines of adaptation. And so, step by step, are produced those marvelous adaptations, those wonderfully perfected and complicated organs familiar to all students of plants and animals. Moreover, this affects not only the structure of the parts of individuals, but the relations between individuals which may become mutually adapted to their advantage, as in the case of parent and offspring, and of animal "societies." Further, it may lead to the development of mutual adaptation between different species to the benefit of both, of which striking examples occur among both plants and animals. One may instance the "symbiotic" association of colourless Fungi and green Algae, known as lichens (*q.v.*), or of green flagellates living in the tissues of the common *Hydra*. Perhaps more wonderful still are the mutual adaptations of insects and the flowers they pollinate, a subject to the elucidation of which Darwin contributed so much. Indeed, the intricate interrelationships of the various organisms inhabiting a given area, their influence on each other's abundance and distribution is extraordinarily complex, and forms the chief subject of a special science, ecology (*q.v.*).

If elimination is to be effective in evolution, if it is to bring about adaptation, the death-rate must be selective; *i.e.*, apart from accidental extermination, the successful survivors should in the long run differ from those which fail. It is easy enough to demonstrate this in the case of larger groups differing by conspicuous characters, and even sometimes of "species" or "races" of which we know the history; but it is often very difficult to prove effects of natural selection at work among closely related individuals differing only by small or, it may be, by invisible characters. Rarely can the failures be directly compared with the successes. Nevertheless some attempts have been made to obtain this direct evidence: for instance, Weldon has shown that in the terrestrial mollusc *Clausilia*, extreme variants are eliminated, while those approaching nearer to the mean of the species are preserved; and Tower obtained the same result with the beetle, *Leptinotarsa*. Harrison has given good evidence that, following on the separation of a wood of pines and birches into one half consisting almost entirely of dark pines and the other of silvery birches, of two marked varieties of the moth *Oporabia*, the light variety has been almost eliminated from the pine wood and the dark variety from the birch wood by the bats and birds which feed on them. Of indirect evidence there is overwhelming abundance. One may here again mention the close adaptation of most forms to their environment; the wide-spread occurrence of protective resemblance between organisms and their surroundings whereby many escape the notice of their enemies; or of warning coloration by means of which species advertize their unpalatability; the failure by constant elimination of certain common extreme variants, such as albinos, to establish themselves; the development of immunity to those particular fatal diseases with which a species comes in contact. No one who has studied living organisms in their natural surroundings, especially in the tropics, can doubt the severity of the struggle, the reality of selection. Here may also be mentioned those striking resemblances between species, especially of insects, sometimes closely allied, but often of separate orders, due to mimicry (*q.v.*). No other explanation of these often astounding similarities in appearance of structure and coloration seems possible but that of gradual convergence through the selection of suitable variations.

What, it may be asked, is the effect of selection on succeeding generations, what part is played by elimination and inheritance in evolution? This question has already been partly answered above when it was pointed out that to be effective, selection must be between individuals differing in their factorial endowments. Among individuals homozygotic for the factors determining a given character, selection of variations of that character due to environmental conditions can have no cumulative effect. But natural species are rarely, if ever, so uniform in their factorial inheritance; on the contrary, they differ, as a rule, as regards a considerable number of factors. Selection of individuals in which a given character is best developed, will then rapidly sort out a strain possessing the most favourable assemblage of factors. But, once this strain has been isolated, further selection can do nothing unless some new mutation in the required direction arises.

Continuous and Discontinuous Variation.—Whether variations are "continuous" or "discontinuous," whether variation takes place by a series of small graduated changes or by sudden large steps or jumps, is a question which has given rise to much controversy. A tendency towards discontinuity is shown especially in "meristic" variation. Thus, a cell will either remain single or divide into two, the antenna of an insect may have either four, five or six joints, the number of dorsal vertebrae in a mammal may vary from 12 to 13, or from 13 to 14. But even meristic variation

is not always discontinuous. As already explained most characters vary sufficiently continuously for their measurements to yield an even curve. The controversy has been obscured by the failure to distinguish between such continuity of variation and continuity in the changes of hereditary factors. Phenotypes may be continuous since the incidence and strength of the modifying conditions are due to chance. Mutations may appear discontinuous if the factorial change produces a striking effect, while in other cases they may be of moderate or even of the minutest size. Since the genes appear to be definite units, it is probable that the factorial changes themselves are mostly discontinuous, but the resulting differences are more or less completely masked or smoothed down in the phenotypes by the modifications. No hard-and-fast lines can be drawn between "sports" and small variations. Which of the two is the more important in evolution is a point on which Darwin was somewhat uncertain, but he finally concluded that natural selection dealt chiefly with the smaller. Certainly these are much the more numerous; and it must surely be easier for complex adaptations to be built up by small steps, than by sudden changes likely to dislocate the existing mechanism.

No arbitrary limit can be set to the "selection value" of a character; its value depends on the intensity of the struggle at the moment. The slightest difference in weight between two seeds carried by the wind may decide that one will reach a favourable spot and not the other; the smallest difference between the staying powers of two animals in a flood may enable one to swim to safety and not the other; the smallest inferiority in powers of resistance to disease may cause one man to perish while another recovers. Moreover, a character, useless during the greater part of the life of an organism, may prove of vital importance at a particular time.

THE CASE AGAINST DARWINISM

Objections to the Theory.—Much has been made by the critics of Darwinism of the alleged uselessness of many characters. Since variation is not in itself adaptive, they may be useful, harmless or harmful, and so long as they remain harmless, useless variations may remain. since they have no effect on the death-rate; but so soon as they increase to a harmful extent, they tend to be eliminated. Only favourable variations can be selected and apparent exceptions to this rule may be due to correlation, which plays an important part in evolution. A factor of inheritance may affect several characters and even the whole organism, so that the alteration of one character by selection may lead to correlated changes in other parts.

Many characters have, however, been asserted to be useless which have subsequently been found to be not only useful, but essential. As our knowledge advances, the functions fulfilled by various organs and parts are daily being discovered. Conspicuous examples are the glands of internal secretion, such as the pituitary gland, formerly supposed to be a useless vestigial structure, but now known to be of the greatest importance. No character can be accepted as useless until its presence or absence has been proved to exert no influence on the death-rate.

It has sometimes been urged by detractors of Darwin's theory, that organisms are pre-adapted and that natural selection does no more than allow what has already been developed to persist. In a certain limited sense this is, of course, true. Selection can only take place between existing forms and variations; and many instances may be given in which organisms have been able to spread into new regions, where others have failed, because they happened to be of suitable structure. Selection cannot be prophetic and such cases are due to chance. But they do not diminish the importance of natural selection in building up organisms fitted to live under special conditions, or organs adapted to fulfil special functions, which is what we really mean by adaptation.

Lastly, it is sometimes objected that if selection cannot be prophetic, if evolution is not due to some purposeful force, it is difficult, if not impossible, to account for the development of such complex organs, since the initial stages would be useless. In this connection it should be remembered that organs are rarely, if ever, known to "begin." Entirely new functions are not suddenly developed. A careful study of what we know of their evolution shows that they are evolved by the gradual transformation of, addition to, or subtraction from something already present. The wing of a bird has had no sudden beginning, but has been gradually transformed from the fore-limb of a reptile. An intermediate stage is seen in the extinct *Archaeopteryx* (*q.v.*). The sharp sting of a bee is the transformed ovipostor commonly found in insects. Even such a highly specialized organ as the eye of man may be traced back to the property of response to light distributed over the surface of the body in the lowest animals. No doubt, owing to imperfect knowledge, there are many cases in which the intermediate stages are unknown and difficult to imagine; but it should not be concluded that they have not existed.

OTHER FACTORS IN EVOLUTION

Isolation.—In addition to the three main factors of evolution so far dealt with, variation, heredity and competition, there are, as Darwin pointed out, subsidiary or auxiliary aids to natural selection. Of these isolation is perhaps the most important. As explained above, species are, generally speaking, not composed of individuals of perfectly uniform inheritance, but are assemblages of intercrossing races, differing from each other by some out of the vast number of genes making up their hereditary equipment. Now, sexual reproduction no doubt is the means of affording ever fresh combinations of genes, but it also works towards preserving an average type by continually mixing varying strains. Selection without isolation may lead to evolution in a straight line, but if divergence is to take place, some sort of isolation seems necessary, and the fitting of organisms to new environments, the development of new functions and structures along ever diverging lines of adaptation, is one of the most characteristic and significant features of organic evolution. Isolation is of several kinds: geographical, functional, structural, psychological. The means of dispersal are various; some organisms, such as microscopic animals and plants, spores, and seeds, are distributed passively by the wind, others by water currents, and still others move from place to place by their own efforts. Geographical isolation is due to physical barriers, mountains, deserts, rivers and oceans, separating groups of land animals. Marine organisms may be divided by the uprising of dry land, and the inhabitants of fresh water by the separation of river basins. Further subdivisions are due to organisms adopting different habitats to which they are adapted. Some live in dry, others in damp, places, some in the shade while others prefer the light, and so on. Aquatic forms may be restricted to certain depths, mountain forms to certain heights. Whatever the reason, isolation, sooner or later, leads to divergence from the parent form. Speaking generally, individuals sufficiently alike to be placed in the same species usually have a continuous distribution, closely allied species are usually found in neighbouring regions, especially if they have few means of dispersal, and they are more unlike the further they have strayed from the original centre of distribution.

Each large land area tends to acquire a characteristic flora and fauna, made up partly of indigenous forms evolved within it, and partly of forms which have migrated into it from neighbouring areas. The more efficient the barriers enclosing it and the longer it has been isolated, the more different will be its flora and fauna from those of other areas. The organisms on an island resemble, on the whole, those of the continent from which it has been separated; many of them, however, are generally found to differ somewhat from the continental types. Particularly significant is the fact that in an archipelago, a species may become split up into as many races as there are islands inhabited by it; as has happened, for instance, with the golden oriole (*Icterus*) in the West Indies. In volcanic oceanic islands which have never been connected with a continent, and whose population is derived from rare strays capable of swimming, flying or being conveyed overseas from neighbouring lands, the number of peculiar species is strikingly large, and here again each island of a group may have its own form. A well known instance is that of the local races or species of birds and reptiles in the Galápagos islands. Such

facts, of which many examples might be given, afford unmistakable evidence of the part played by geographical isolation in evolution. Somewhat similar isolation and divergence seem to result from parasitism; for the tendency of the parasite to restrict itself to one host, to which it becomes closely adapted, may lead a parasitic form to split into as many different races as there are kinds of host. Similarly with plants fertilized by insects, the flowers tend to become specialized in various ways to attract certain kinds, while the insects undergo corresponding specialization to obtain nourishment from the flowers.

Many organisms, though closely allied, living in the same locality and coming into close contact, do not interbreed. Their crossing is effectually prevented by variations in structure, habit or temperament. The most important "physiological" barrier is sterility, of which there are several kinds due to different causes. Mere difference of size may prevent interbreeding, or differences in the structure of the copulatory organs, as in many insects; also the attainment of sexual maturity at different times of the year. Variations of the germ-cells themselves lead to what may be called true sterility, of which there are various degrees. Fertilization may be imperfect or not take place at all, probably owing to incompatible differences in the protoplasm, in the number and character of chromosomes, or in the hereditary factors. Even if zygotes are formed they may fail to develop normally, or the offspring, if they reach maturity, may themselves be sterile, as in the mule. Whatever their origin, these various barriers to free and fertile interbreeding favour the preservation of divergent characters.

It may here be pointed out that other results follow on fertilization besides the activation of the zygote and the mingling of genes already mentioned. It is popularly held that close and continued inbreeding leads to harmful results, to loss of fecundity and a weakening of the race; while outbreeding or intercrossing is supposed to have beneficial results, to increase fecundity and general vigour. The almost universal forbidding of the marriage of near-of-kin in human societies is consonant with this belief; and the many devices evolved in nature to facilitate cross-breeding and prevent self-fertilization among hermaphrodite plants and animals point to cross-breeding being advantageous. The question, however, is by no means simple and cannot here be treated in detail (*see* INBREEDING). It may be pointed out that continued close inbreeding due to self-fertilization does occur in many plants and in some animals (especially parasites) in nature, and may be carried on artificially without harmful consequences, provided vigorous individuals are selected for the purpose. One of the results of inbreeding is to reduce heterozygosity and secure homozygosity among the progeny; the opposite follows from cross-breeding. Now, since unfavourable characters are often determined by recessive genes, they are apt to become manifest in the individuals homozygous for them. Hence inbreeding of tainted stocks tends to bring out albinism, deaf-mutism and feeble-mindedness in man; while no such evil results will follow if these particular genes are absent from the inheritance. On the other hand, there is ample evidence that the crossing of individuals or races differing slightly from each other in their inheritance or factorial make up, generally leads to increased vigour in the offspring. This beneficial result, apparently due to some degree of heterozygosity, is secured in nature by the separation of the sexes, and has long been known to breeders.

Great has been the influence of sex on the evolution of organisms. To secure the nourishment, distribution, fertilization and survival of the reproductive cells is the chief function of all creatures; to these ends have been developed that wonderful diversity and elaboration of bodily and mental structure found in living nature.

Sexual Selection.—Another important auxiliary factor in the evolution of animals was called by Darwin sexual selection. The many and often conspicuous differences between the two sexes, other than those of the reproductive organs themselves, are known as secondary sexual characters. They occur among the higher groups of active animals and enable the sexes to find and recognize each other, and to accomplish the act of copulation; as, for instance, the prehensile organs, the specialized organs of sense, the scent organs, the sound-producing organs, the call notes of insects and vertebrates. They also include special organs of attack and defence used by rival males in fighting for the possession of females; and the wonderful developments in structure, coloration and behaviour serving to attract and stimulate the opposite sex. Sexual selection may be considered as a subordinate, special kind of natural selection taking place within the limits of interbreeding groups of animals. It is one of the great triumphs of Darwin to have provided a rational and utilitarian explanation of the evolution of these characters.

AFFINITIES

Evolution and Classification.—It was to a great extent the study of comparative anatomy and embryology pursued with the object of obtaining a trustworthy basis for classification that helped most to the acceptance of the doctrine of evolution. Notwithstanding their great diversity, it was soon observed that organisms form, on the whole, an ascending series increasing in complexity of organization, and further that they fall into great groups or types made up of forms of similar build, but varying much in details and proportions according to their adaptation to different modes of life. These great types do not form a linear series leading from one to the other, and their relationships are better expressed as diverging branches from a common stem. In fact the anatomical resemblances and differences between organisms can only be satisfactorily interpreted as the result of their derivation and transformation from a common ancestor. Phylogeny, or the science dealing with their affinities or "blood-relationships," is the only secure foundation of classification.

Palaeontology, the study of extinct fossil forms, has done much to strengthen this conclusion; likewise embryology, the study of the ontogeny or development of individuals, which has thrown much light on obscure relationships and familiarized naturalists with the notion that small and simple beginnings may give rise to large and complex final products. Classification, then, is an attempt to group organisms according to their natural affinities and to trace out their pedigrees. Similar individuals are grouped into species, species into genera, these into families, orders, classes, phyla, divisions of increasing size and importance. The history of the conception of "species" has been mentioned at the beginning of this article. All sorts of attempts have been made to define species in accordance with modern theories of evolution; but no stricter definition seems practicable than this, that a species is composed of closely allied individuals descended from a common ancestor, which normally interbreed, and are sufficiently alike and sufficiently distinguishable from related forms to be conveniently called by the same name.

Much stress has been laid on sterility between two forms as a test of their specific rank; but although interspecific sterility commonly occurs, perhaps favoured by natural selection to prevent intercrossing, it is by no means universal. Every gradation occurs between absolute sterility and perfect fertility in crosses between well-recognized species, especially among plants. Indeed many botanists claim that inter-specific hybridization is a frequent source of new species.

De Vries tried to define "elementary species" as strains distinguished by a single mutation. But mutations may be of any size from "sports" to scarcely perceptible differences, and most, if not all groups distinguished as species seem to be composed of interbreeding races differing from each other by small factorial differences, which races have sometimes been separated out by careful selection and breeding.

Species living at the present day represent the closely allied individuals at the extremities of the surviving twigs of the phylogenetic tree. If they have become marked off from allied species, it is because the intermediate connecting individuals have died out. Along the branches leading to them and along the main stem, there are no points at which a species can be said to begin or to end. It is only for convenience in description that the name species can be applied to ancestral forms along these lines of gradual evolution. The only "fixed points" in a phylogenetic

system of classification are the points of bifurcation, where one branch diverges from another, and it is here that generic, family and other divisions should be made.

The living species are those which have succeeded in the struggle for existence. The greater the extinction of allied forms the more widely do the survivors become separated from each other. Hence as the phylogenetic tree grows in the course of geological ages it tends to give off ever spreading branches. Rarely, however, is the geological record well enough known to enable us to demonstrate the exact point of origin of a group, and most classifications are but approximations to a correct phylogeny.

Degeneration.—Mere resemblance is not always a sure guide to affinity. Forms which differ widely in the adult state often resemble each other much more closely in young or embryonic stages. By observing their development, affinities can sometimes be discovered which would scarcely be otherwise suspected. For instance, the sea-squirts (Tunicata, *q.v.*) are essentially sedentary animals which have become highly specialized and in some respects degenerate, owing to their peculiar mode of life. The adult lives fixed to the sea-bottom, and is of simple sac-like structure, little resembling an ordinary vertebrate; yet the free-swimming larva has the dorsal central nervous system, gill-slits and notochord characteristic of the vertebrates. The barnacles (Cirripedia) have also taken to an adult fixed life and lost many of the features of the Crustacea (*q.v.*)to which their larval stages show they belong.

Other striking instances of specialization accompanied by degeneration commonly occur among parasites. Since they often absorb their food directly from their hosts, they tend to lose organs of locomotion, special sense organs and even the alimentary canal, and devote themselves to producing enormous numbers of eggs and young to infest new hosts. Frequently they become simplified beyond recognition, and their true affinities are betrayed only in their development.

Degeneration, or the loss of special structures no longer required in the new environment to which an organism may become adapted, is a frequent phenomenon. One of the great merits of the doctrine of evolution by natural selection is that it accounts for this simplification. For both progressive and retrogressive mutations occur; which will be selected depends on the needs of the organism at the time.

Vestigial Organs.—One of the results of change of life-habit or environment is to leave behind, in the course of evolution, parts and organs, once perhaps of vital consequence, but now of little or no use. Numberless such vestigial organs are known amongst plants and animals, and their presence has been considered as affording the strongest evidence for evolution. Unless they become adapted to fulfil some new function, they are apt to diminish and finally disappear, particularly if their presence is in any way harmful. Such vestiges are the splints representing the last trace of the side-digits on the foot of the horse, the small bones embedded in the body-wall of whales and representing the vanishing hind-limb, the vermiform appendix of the intestinal coecum and the hidden little bony tail of man. Flightless birds, like the kiwi (*Apteryx*) of New Zealand, preserve vestigial wings concealed below the feathers.

In the course of evolutionary progress, however, through variation and selection organs are usually transformed and converted to new uses. It is doubtful whether any really useless parts are ever preserved for long unless they are insignificant, and many of the so-called vestigial organs are now known to fulfil important functions. The small pineal organ in our brain is, in a sense, the degenerate remnant of a dorsal eye still fairly well developed in certain living lizards and the lamprey, and there is evidence that it was possessed by most of the primitive fossil fish and land vertebrates; but in ourselves and other mammals, though it has lost its primitive function, it secretes essential substances into the circulation.

Homology, Analogy and Convergence.—Organs converted to new uses become modified and adapted in different ways, along divergent lines of evolution. However different they may become, if they can be traced back to the same origin in a common ancestor they are called homologous. The tracing of homologies is one of the means of determining affinities. For instance, the creeping foot of a mollusc, as seen in the snail, may become an expanded flapping swimming organ in marine pteropods, a jumping organ in the cockle or be converted into prehensile arms in the squid. Our own five-fingered forelimb is homologous with the forelimb of a horse, the swimming paddle of a whale, the wing of a bat or of a bird. In spite of their modifications homologous organs generally show the same essential parts, the same fundamental plan of structure. Intermediate steps between the extremes of specialization may often be found, especially among fossil forms. However much the resemblances may be obscured or lost in the adult, they are generally clearer in the earlier stage of development, in which the common origin of the most diverse organs may be manifest.

But all similar parts are not necessarily homologous, and just as adaptation to different uses leads to divergence, so adaptation to the same function may lead to resemblance. Organs of quite different origin may become so alike by convergence as to deceive the practised eye of the expert. Such specialized parts which cannot be traced back to a common ancestor are called *analogous*. As examples of analogy may be mentioned the wing of a bird and that of a butterfly, our own jaws and those of an insect. Organs may be both analogous and homologous, for example, the wings of the bat, the bird and reptilian pterodactyl are homologous in so far as they are all forelimbs, but analogous in so far as they are organs of flight independently derived from a walking limb. All such cases are powerful evidence in favour of evolution; indeed it is difficult to describe them without assuming their evolutionary origin.

What has been said above of organs is equally true of organisms as a whole. While evolution as a rule leads to divergence, it may by adaptation to similar environments and modes of life, lead, on the contrary, to *convergence* in colour, shape, structure and behaviour. Unrelated forms may thus become deceptively alike. The amphibian *Siphonops*, the lizard *Amphisbaena*, the snake *Typhlops*, all creeping and burrowing forms, have lost their limbs and come to resemble an earthworm. Striking cases of convergence are known among plants; for instance, the independent acquisition of a cactus-like structure by representatives of the Euphorbiaceae, Asclepiadaceae and Compositae in adaptation to dry desert-like conditions.

Recapitulation Theory.—The study of embryology affords not only valuable help in the tracing out of obscure affinities, but also strong evidence in favour of the doctrine of evolution. As pointed out long ago by K. E. von Baer, the embryos of forms belonging to different groups are generally more alike than are the adults. Among vertebrates, for instance, the embryo reptile, bird and mammal possess gill arches like those of a fish at a corresponding stage of development. From such evidence it was rashly concluded that in the course of its development an organism passes through stages approximately representing the series of ancestors which preceded it, and E. Häckel enunciated his famous "Biogenetic Law" that ontogeny recapitulates phylogeny. This was a gross exaggeration, and all that can be maintained is that the ontogeny of an individual may more or less recapitulate the ontogeny of its ancestor. Owing to new conditions and adaptations the course of ontogeny may come to deviate from that of the ancestor at any period from egg to adult; stages may be omitted, larval specializations may be intercalated, new structures developed. The fish, the reptile, the mammal, do not really start from the same point and pass through the same stages; they are fish, reptile and mammal respectively from their beginning. Their ontogenies are similar only in so far as their zygotes contain the same factors and develop under the same conditions.

Apart from differences of environment, the basis of the evolutionary changes seen in a phyletic series lies in the alteration of the factors contained in the continuous stream of germ-plasm, not in the adult organisms derived from it. And here it may be mentioned that this progressive or retrogressive change involves not only the gross structure, but also the intimate chemical composition of the germ-plasm, of the very molecules of which it is made up. There has been a phylogeny of the genes and of their

ingredients, as there has been a phylogeny of the organisms themselves. Consequently protoplasm and its products come to differ along diverging phyletic lines. For instance the red colouring matter of the blood (haemoglobin) differs slightly in different vertebrates; so also starch in various plants and many of the proteins in all organisms. The degree of resemblance may afford some measure of affinity.

Help in tracing relationships has recently been derived from the study of the physico-chemical reactions of the blood and other body-fluids of vertebrates. The "precipitin test" applied to the blood affords evidence, for instance, that man is more nearly allied to the anthropoid apes than to the lower monkeys, and to the latter than to the other Mammalia. Some of the phenomena of interspecific sterility mentioned above are probably related to such divergences in chemical composition.

GEOLOGICAL TESTIMONY

Palaeontological Evidence.—Perhaps the most convincing testimony to the truth of the doctrine of evolution comes from palaeontology (*q.v.*). Incomplete and fragmentary as it is, this geological record shows the actual links in the evolutionary chain, and also the order in which they fit into the series. Speaking generally, as we pass from the recent to older deposits, the fauna and flora appear less and less like those of the present day. The higher and more specialized groups are replaced by lower, more generalized forms, until in the earliest fossiliferous strata only a few of the lowest types remain. The fossil organisms found are, naturally, chiefly those possessing hard skeletons capable of fossilization, and only those individuals which happened to die under conditions favourable for preservation. The record is, therefore, very imperfect and often interrupted by gaps. From the fragments of the earliest-known fossils it is clear that life must have existed long before, since they already show considerable diversity. Already in the pre-Cambrian epoch there are traces of Protozoa, marine Algae and, perhaps, annelid worms. The earliest known vertebrates are the armoured fish of the Silurian, an epoch in which are represented most of the large groups of invertebrates, and in which first appear land plants. Traces of land air-breathing vertebrates occur in the Devonian, but it is not till the Carboniferous that they become common. During the latter epoch flourished spore-bearing ferns and other primitive plants; cycads, ginkoes and conifers dominated in Permian times, to be replaced in the Cretaceous, to a great extent, by the modern flowering plants. During this vast period many great changes occurred in climate and the distribution of land and sea, which must have greatly affected the course of evolution. In a general survey we can watch evolution at work, see its results writ large; many problems about variation, survival, extinction and the like, so difficult to solve when dealing with individuals, seem simplified on such a large scale. Having reached a certain favourable level of organization, a group expands and flourishes; divergent adaptive radiation leads to specialization in various directions. The advantage of such radiation is that more organisms can secure a place in a given region if they adopt different modes of life and of feeding; just as in a human community more individuals can make a living if they take to different trades and occupations. Specialization may secure temporary success, but almost inevitably entails loss of adaptability if the general conditions alter or new competitors enter the field; there follows decline and extinction, and replacement by some other more adaptable form which reaches a higher level of organization. Such has been the fate of most groups as revealed by the palaeontological record.

So we often find scattered over the globe isolated and specialized remnants of a once extensive group betraying their origin by their archaic structure. For example, the arthropod *Peripatus* and a few closely allied genera, in central and south Africa, central and south America, the Malayan and Australian regions; or the lung-fishes (Dipnoi), of world-wide distribution in the fresh waters of Palaeozoic times, now surviving only as *Ceratodus* in Australia, *Protopterus* in central Africa and *Lepidosiren* in south America.

Most remarkable are the number of abortive branches of the phylogenetic tree. Over and over again large and flourishing groups are seen to dwindle quickly to insignificance, or die out altogether. These results of selective elimination are obvious, but the causes which bring it about are by no means so clear. Climatic changes, catastrophes, epidemic diseases may account for a great deal, but overspecialization seems to be the most usual contributory cause. Natural selection can provide only for the needs of the moment; it cannot be prophetic. Once committed to some narrow path of specialization, it may be difficult, if not impossible, for an organism to turn aside. Once an organ has been lost, it can hardly be regained, though it may sometimes be replaced by an analogous structure.

Evolution of the Tetrapods.—A glance at the history of the land vertebrates is very instructive. Derived from some fish-like, aquatic ancestor in pre-Devonian times, they flourished in Carboniferous times as clumsily built Amphibia, and gave rise to several highly specialized forms. But of the whole class, only a few remnants occur at the present day, the salamanders and newts (Urodela), the rare leg-less Apoda and tail-less frogs and toads (Anura), which alone may be considered fairly successful. Already in Permian times they were beginning to feel the competition of the reptiles, more completely terrestrial, agile and highly organized animals, sprung from some unspecialized branch of the amphibian stem. So dominant did these Reptilia become that the Mesozoic age is frequently called the age of reptiles. They displayed an astonishing variety of form and size and became specialized for life on land, in the air and in water. Yet at the end of the Cretaceous they were already on the wane, and of the numerous branches from the reptilian stem only the tortoises, lizards and snakes can be said to have held their own to the present day; scattered Crocodilia still survive in fair number, but the Rhynchocephalia are represented by only a single species, *Sphenodon*, on small islands off New Zealand. The great group of dinosaurs is entirely extinct. The reptilian type gave rise to two classes destined to replace it in almost every sphere. As shown by the beautifully intermediate form *Archaeopteryx* of the Jurassic, the birds arose from some group allied to crocodiles and dinosaurs, and quickly gained the mastery of the air. The mammals, on the other hand, made their appearance in early Triassic times as small humble creatures which did not make much progress till the later Cretaceous and Tertiary ages. Their origin can be traced step by step to the early undifferentiated reptiles known as the Theromorpha. Once the mammalian grade of structure was reached with its many advantages and great adaptability, it soon triumphed over all others and succeeded, not only in establishing itself on dry land, but also invaded the sea and the air. Adaptive radiation gave rise to great divergent modifications of the mammalian type in early Tertiary times, and the Mammalia are at present dominant on land. But this position was not gained without a hard struggle and of the many branches of the mammalian stem, few have lasted to recent times and still fewer are still expanding. The order Primates, to which man belongs, can be traced back, like most of the mammalian orders, to small unspecialized ancestral forms in the Eocene epoch.

Rate of Evolution.—The rate of evolutionary change has varied greatly along the different branches of the phylogenetic tree. Some forms have scarcely altered during long geological periods. The molluscan genus, *Patella*, to which belongs our limpet, dates from the Silurian epoch, a time at which also lived a scorpion differing but little from living species. The brachiopod, *Lingula*, has scarcely changed since the Ordovician. Presumably these persistent types were early well enough adapted to withstand competition in certain suitable environments still occurring at the present day. That evolution has usually taken place by small steps is proved by the very gradual transitions from one form to another as the fossils are traced from stratum to stratum. Wonderful series of graduated forms have been found among trilobites, brachiopods, ammonites and other molluscs, and also among vertebrates. The more complete the record the more gradual the transition. The history of the horse offers a good example. Starting in the basal Eocene from a small generalized ancestral ungulate with four or five digits on each foot and the full complement of short-cusped teeth, the specializations peculiar

to the Equidae can be seen gradually to appear: increase in size, lengthening of the skull, conversion of the biting molar teeth by lengthening of the crown and fusion of the cusps into grinding ridges, reduction of the lateral digits to insignificant vestiges as the feet become adapted to running on hard ground. Even the horse type, however, has not been evolved along a single straight line, and many side-branches were produced which failed to survive.

Other mammalian orders have had a very similar history, and almost always increase in size has been a conspicuous feature of their evolutionary transformation. This has also occurred among plants, and many groups of invertebrates, such as ammonites and arachnids. The large stegocephalian Amphibia, the gigantic dinosaurs among Reptilia, and Titanotheria, Dinocerata and Proboscidea among Mammalia are examples of the same development. This great increase in size doubtless secured temporary success and world-wide expansion; but usually the success has been short-lived and was quickly followed by decline and extinction. From these and similar phenomena it has sometimes been concluded that "trends" may be discerned in evolution leading organisms along some definite line of specialization. If by this is meant that behind ordinary evolutionary processes there is some mysterious force, something other than natural selection of variations, guiding organisms inevitably along some preordained path and guiding them often to destruction, such a view cannot be accepted as a scientific explanation. The dangers of specialization have already been insisted upon; increase in size is a form of specialization, often clearly advantageous in overcoming enemies and other destructive influences.

BEHAVIOUR

Adaptability.—One of the most valuable properties enabling individuals to survive in the struggle for existence is adaptability, that power of responding to different stimuli in different ways. It has been pointed out that the total potentialities of an organism are determined and limited by its inheritance, what particular characters come to be developed depends on the environment, internal and external. The more the assemblage of transmitted factors can respond in various advantageous and suitable directions, the greater the power of accommodation to new or unusual conditions, the greater the adaptability. Thus, a plant so endowed that it will in dry or damp conditions take on a suitable form, will be able to succeed and spread in climates and localities in which it would otherwise fail. The same species of plant, indeed, the same individual if transplanted, will take on a very different form if grown near a mountain-top or in a lowland valley; *Ranunculus* will acquire one appropriate shape if grown in water, another if grown in air. Natural selection can thus build up favourable responses adapted to a variety of needs, and the potentialities of an organism are of primary importance.

One of the most efficient ways of responding advantageously to various needs is by correspondingly modifying "behaviour." Behaviour is response expressed in movements; it is a special kind of accommodation and has developed in association with the power of storing up the impressions of past responses; it enables the organism to "learn" and benefit by "experience." These new powers "emerge" with the elaboration of the sense-organs and of the nervous system. In the long run it is adaptability, and more especially "brain power" which wins in the struggle.

Instinct and Intelligence.—So far nothing has been said about the rôle of mind in evolution. It is a subject which cannot be discussed adequately within the scope of this article (*see* EVOLUTION AND MIND); but something must be said about the evolution of instinct and intelligence (*see* COMPARATIVE PSYCHOLOGY). From the strictly scientific point of view, the whole course of evolution may be represented as an unbroken series of physico-chemical events, each step conditioned by preceding steps. But corresponding to this series is a chain of mental events. To every mental process or event, whether of the most complex or "highest" kind in the mind of man, or of the simplest or "lowest" in the most primitive organism, there corresponds some physico-chemical change. The slightest disturbance in the metabolism of the brain, due to any stimulus whatsoever, will be accompanied by a disturbance in the mental processes. Our sensations, emotions, thoughts—all our mental activities are correlated with changes in our bodies of which our behaviour is the outward and visible expression. Of our own mental processes we have direct knowledge in so far as we become conscious of them; but of the existence of similar mental processes in other organisms we can only infer by observing their structure and behaviour. The gradual elaboration of the sense-organs and nervous system, and behaviour seen in the evolutionary series, more especially of animals, we judge to have been accompanied by a corresponding development of mental powers. The closer these physical characters resemble our own the more like our own we believe their minds to be.

Natural science is not directly concerned with metaphysical explanations or philosophical systems; it does not seek to explain the ultimate cause or purpose of existence, the ultimate nature of things or of knowledge. Nevertheless, when dealing with the scientific description of evolutionary processes, we should endeavour to realize what are the limitations of scientific method, and what is the scope of natural science within which its conclusions may be accepted.

What are commonly distinguished as mind and body are two one-sided incomplete abstractions, made in our own conscious minds and subject to its limitations. These two abstractions represent perhaps two aspects of some whole, more fundamental, reality. Like the two sides of a plane surface, they cannot both be seen at the same time. The mental and physical series of events are not two independent parallel series; so far as we know, one cannot exist without the other; they are indissolubly connected. Neither can one be said to be produced by the other, or be described in the same terms. The mental series cannot be held to interfere with, guide or break into the interconnected chain of physico-chemical events. The two series may perhaps be distinguished as respectively subjective and objective,—the one is felt, the other observed. The question, "What has been the influence of the mind in evolution?" has no scientific meaning, and should rather be asked in some such form as this: "What part has been played in evolution by that complex system of sense-organs, nervous system, etc., to which correspond higher mental processes such as those we know in ourselves?" With such a question natural science can legitimately deal, even though a complete answer cannot yet be given, owing to our very incomplete knowledge of the metabolic processes involved.

The adoption of this position as, at all events, the only practical scientific working hypothesis, entails the conclusion that to every metabolic process in a living organism there corresponds some sort of mental process, that every organism may be said to have some sort of mind be it ever so "low" or rudimentary. And this conclusion is amply justified by the observation of behaviour, whether "instinctive" or "intelligent."

Since the two series are indissolubly correlated, the "laws" of variation and inheritance hold good in mental as in material evolution. This explains how man, by breeding and selecting the requisite mechanism, has altered the behaviour and with it the mental equipment of races of domestic animals.

Tropisms.—An analysis of the behaviour of the lower organisms shows that, to a great extent, it is based on direct responses to external stimuli. Such responses of movement are called tropisms, and distinguished as phototropism, geotropism, hydrotropism, etc., according as the stimulus influencing metabolism is light, gravity, moisture, etc. Thus, owing to more active growth on one side than the other, shoots of plants grow towards and roots away from the light; the former are positively, the latter negatively phototropic. Similarly shoots grow away from, and roots towards, the centre of the earth; here the stimulus is the action of gravity. If light falls on a shoot at an angle to the pull of gravity, the resulting direction of growth will be a compromise between the two tropisms. The same tropistic responses occur with fixed animals, for instance hydroid zoophytes. It is important to realize that the motions of free-moving animals are likewise governed by tropisms. As is shown by the swimming of unicellular Algae or Infusoria, the creeping of a snail, the flight of an

insect, organisms may be positively or negatively phototactic. Thus the behaviour may be made up of various tropistic responses to stimuli. The kind of response evoked depends on the kind of stimulus, and also on the structure and condition of the mechanism stimulated. A well-fed animal will react differently from a starved one, a young animal differently from an old one.

Another important element besides simple tropisms in the behaviour of organisms is known as "differential sensibility," or the reaction to sudden and marked changes in the strength of a stimulus. Leaves may move or flowers open in strong light; a shadow passing across may cause a worm to contract, a fly to escape.

The usual behaviour of lower organisms; their movements when seeking food; their habit of gathering together in dark, warm, or damp places; their sexual instincts; their instincts connected with reproduction, such as the laying of eggs on appropriate substances for the young to feed on, and so forth, can be interpreted as composed of such simple responses. Instinctive behaviour is a chain of interlocked simple responses each one of which acts as a stimulus to the next. An environmental stimulus releases the first and the others inevitably follow to a definite and predictable end, provided the necessary conditions are present.

Tropistic response is, of course, based on the fundamental irritability of protoplasm. It varies in extent and direction, and, like other variations, may be useful, harmful or indifferent. Useful instinctive behaviour may be built up by the natural selection of tropisms of "survival value" into the wonderful instincts displayed, for instance, among social insects (*q.v.*). Such complex chains of reactions will be inherited, for they depend for their appearance on the interaction of certain transmitted factors of inheritance with the conditions present in the normal environment. Among animals, simple responses or tropisms become "reflex actions" owing to the great differentiation of the tissues, and elaboration of the mechanism consisting of sense-organs to receive special stimuli and a nervous system to convey impulses set up by them to muscles which carry out the movements. Sequences of interlocking and co-ordinated reflexes form the basis of the most complicated behaviour; yet another element, "associative memory," enters more especially into its more elaborately differentiated forms. It depends on the fact that the effects of a response may persist as a lasting impression on the organism, in the form of some physico-chemical change which serves as an internal stimulus to modify subsequent responses. The cumulative effects of past responses may thus greatly influence behaviour.

DELIBERATION AND MEMORY

Intelligent Behaviour.—Now instincts are relatively fixed interlocked series of responses to external and internal stimuli, and correspond to a mechanism specialized to respond in a particular direction; once started they proceed to a predestined end. Intelligent behaviour, on the other hand, depends on the fact that although the characters of an organism (including its behaviour responses), are necessarily determined and limited in range by inheritance, yet within that range they are not predetermined in any one direction. Just as a zygote may give rise to as many different kinds of phenotypes as there are varieties of environments capable of moulding its development, so the particular behaviour may vary according to the stimuli received. The cumulated effects of past responses, together with the new stimuli, make up the total of conditions which determine the final response or behaviour. The "choice" between alternative courses of behaviour is the result of the balance struck between these various influences. So intelligent organisms are said to benefit by "experience." Example, precept, tradition, education, are all external stimuli which may influence conduct and leave lasting effects which may act as internal stimuli modifying further behaviour. But, of course, these effects are not transmitted directly, and the stimuli have to be applied anew at every generation if the results are to reappear.

No hard-and-fast line can be drawn between instinctive and intelligent behaviour, and they are usually combined; the rudiments of both seem to occur in the lowest organisms, but it is in the higher animals and more especially in man that intelligence has reached its highest development.

As the sense-organs and nervous system advance in complexity and perfection, new qualities emerge marking new levels in mental development; consciousness is one of these. We cannot tell at which stage in phylogeny, consciousness arose. In the case of our own species we can determine approximately at what stage consciousness begins to manifest itself, as the tissues become differentiated in ontogeny; but, with regard to its evolution, it can only be said that it probably appeared, as we know it in ourselves, when the cerebral hemispheres reached the high state of development seen in man, though the lower organisms may possess it in some simpler stage of development. Very striking in a survey of the evolution of the vertebrates, is the steady increase in the relative size and complexity of the brain, the centre of co-ordination and storage-house of past impressions, as we pass from fish to amphibian, reptile and mammal. This is particularly conspicuous in the Primate series leading up to man. Most of the structural peculiarities of the human body are related to the great development of the brain, in other respects it differs but little from that of our nearest relatives, the anthropoid apes. Man's great capacity for retaining the impressions of past responses, and for bringing them to bear on responses to new stimulations, has led to the wonderful growth of his powers of adaptability to new and varying conditions. The acquisition of stereoscopic vision and the power of fashioning and using implements were important steps in the evolution of modern man. Brain power, not brute force, has secured him his mastery of the world. It is a grave mistake to represent this success in evolution as due merely to individual strength, skill and foresight. The triumph of the human race over the lower organisms, and again of the higher races over the lower, has been brought about through mutual help, co-operation, self-sacrifice and the subordination of the individual.

Patriotism and religion, art, science and literature, have all their survival value and play a useful part in evolution. Morality appears not as an unrelated external force working against a ruthless and unmoral cosmic process, but as a product of evolution and an important influence moulding its development. We may hope and believe that in the long run those civilizations which are founded on justice and liberty, on law and order, on sound morality, will succeed best and last longest.

EVOLUTION AND MIND. In current usage the word "evolution" is sometimes restricted in such wise as to render it applicable only to plants and animals, sometimes so extended as to be applicable throughout nature. Closely connected with this difference of use is the place assigned to mind in or in relation to nature. Some of those who advocate the restricted usage urge that evolution is due to the agency of mind; most of those who accept the unrestricted usage interpret mental progress in terms of evolution.

Unrestricted Evolution.—Since the noun here stands for a concept of wide range it needs suitable qualification to indicate its special application. Thus we may discuss cosmic, organic, mental, or social evolution; the evolution of the solar system, of a continent, of scenery; of this or that family of animals or plants; of the atom, the molecule, the crystal. It is clear, therefore, that one must state that which is common to each of these several instances. The noun must have in all cases some comprehensible meaning, though this can only be expressed in comprehensive form. It may take form in a broad generalization. Thus one may say that any set of events or state of affairs, physical or mental, which exemplifies evolution is a passing phase in an orderly sequence and comes into existence under such conditions that its place in the sequence, its relations to precedent and subsequent phases, and its relations to other surrounding events, are interpretable under the accredited method of scientific procedure.

There is, however, difference of opinion as to the distinctive character of the method of procedure in inductive science. Some say that the accredited method in physics is now a discredited method in biology. Each writer should therefore state what he means. That which is here meant may be best expressed in terms of events and relations, on the understanding that things, such as molecules or crystals, and living organisms, such as animals or plants, are, for science, no more and no less than orderly clusters of events in relation. One finds that clusters of events and sets of events are in quantitatively changing relations to each other—relations temporal, spatial, and physical, and those which, in the broadest sense, we speak of as mental. One finds that with change in these relations the course of events changes. Hence one says: Given such and such modes and changes of relatedness, such and such is the course of events.

It is clear that any course of events implies temporal advance. Selecting, then, some set of events as a field of inquiry, one makes three successive snapshot records of three phases in temporal advance. If all three phases are alike there is no evidence of evolution. But if the phases are different, say l, m, and n, we have the kind of evidence on which the unrestricted concept of evolution is based—unrestricted because it is applicable to *any* set of events which is the subject-matter of inquiry. At the phase m the course of events differs in character from that current at the precedent phase l, and from that current at the subsequent phase n. That, however, is only what one observes. In a scientific interpretation of what one observes one seeks an answer to the question: What changing relations are in being during the changing course of events? This subdivides into two: (1) What are the intrinsic relations within the given set of events? (2) What are the extrinsic relations to other events? If answers can be given to these questions the observable passage through the phases l, m and n is scientifically interpreted.

If the snapshots are taken at wide intervals of time, and if the phases l, m and n are markedly different, one may be unable to say what relations, intrinsic and extrinsic, are or were in being during the time-span intervening between the snapshots. This is the chief difficulty that attends the interpretation of the irrecoverable past. The events themselves and their inner and outer relations have to be filled in under more or less probable conjecture.

Where evolution is in progress in like sets of events with like routine of advance, snapshots can be taken at shorter and shorter time-intervals. One must realize that in practice l, m and n symbolize recorded observations, and that difference in symbol denotes difference of character. If there be no difference of character, there is no evidence of evolution. One's aim is to get records at such minimum intervals in next-to-next snapshots as may give evidence of evolutionary change. A further question then arises. Is the difference at minimum interval such as to lead us to infer a seemingly sudden jump from next to next? If so, the new character is said to be "emergent" (*see* EMERGENCE). In some cases there do seem to be critical turning-points—for example, from atom to molecule, or from molecule to crystal unit, or from not-living to living—in the characters of some clusters of events, with new modes of relatedness that swiftly, if not suddenly, appear on the scene of nature.

Evolution and Dissolution.—We now turn to a question of different import. Does every enchained sequence of natural events, in so far as there is observable change, furnish an instance of evolutionary advance? It was one of Herbert Spencer's noteworthy contributions to the discussion of changes in sequential order that he sought to distinguish phases of events as in some sense lower and higher. On this distinction there follows that between passage from lower to higher, for which he reserved the name "evolution" and the passage from higher to lower, which Spencer spoke of as "dissolution." Since both directions in passage occur throughout nature, it is desirable thus to use different words for one and the other, or, at all events, to distinguish between *positive* and *negative* (or *progressive* and *regressive*) evolution. There is, however, difficulty in formulating criteria of higher and lower, especially as applicable to all instances of one or other respectively; for n may be higher or lower than m in complexity, in integral unity, in quality or in value. So long as due provision be made for quality and value, it may be suggested that complexity in the constitution of any l, m or n, and unity of the plan or organization may generally serve to distinguish higher from lower in any context under consideration.

In each specific context some distinction between lower and higher is commonly drawn by those who deal with matters which fall within that context. Progressive advance from lower to higher, or regressive degradation or degeneration in the opposite direction, has often to be reckoned with. And in the light of snapshot evidence the question often arises whether some m has come into existence under positive or under negative evolution. Let m, for example, be an atom of lead. There is evidence of its natural origin in isotope form, by regressive evolution (Spencer's dissolution) of the uranium or the thorium atom. But there is, as yet, no direct evidence of its origin by progressive evolution. If, however, m be a molecule, say of water, there may be evidence of its origin in this instance by progressive evolution, in that instance by the dissolution of some more complex molecule. And if m be an organism, or some phase of its life, or some stage in the development of one of its organs, the present status of m may be on the ascending line of evolutionary progress from lower to higher or the descending line of regressive degeneration.

Biological Evolution.—Under division of labour special departments or branches of scientific inquiry have been demarcated for the prosecution of intensive work and thought. The biologist chooses as his province the field of living organisms under intrinsic and extrinsic relations. He may accept the hypothesis of unrestricted evolution; but he applies the method of scientific procedure within his selected province of inquiry. Evolution is for him a doctrine of descent in affiliated organisms.

In dealing with paleontological records of extinct animals, say of the horse-type, his snapshot evidence of l, m, and n is necessarily widely spaced. Intervening phases must be filled in by inference. Let us suppose the "missing links" are such as may be inferred if a generalization based on the known l, m, n be valid. The subsequent discovery of links heretofore missing adds to the probability of the generalization. The method of procedure is substantially that of interpolating observed points—the closer the better—on a curve of probability. The conditions are different when the biologist deals, in terms of l, m, n, with adults of three successive generations. Even here, however, there is a considerable time-interval between the records of individuals that have reached the requisite stage of development. But when we turn to this individual development, snapshots may be taken at minimum intervals. Hence in embryology one comes to close quarters with next-to-next phases of advance. It then remains to correlate the story of individual development (ontogeny) with that of racial evolution (phylogeny).

Turning now to what one may speak of as linear genetics one brings under observation a short span of a germinal line of advance—or, under gametic union the relational intersection of two such lines—stretching back to more and more primitive organisms. Here, too, the aim is to get next-to-next phases in advance at minimum interval, to be interpreted in terms of relations extrinsic and intrinsic.

Biochemical Evolution.—In the method of treatment here adopted for expository purposes any three phases or stages of evolutionary advance are symbolized by l, m, and n. In all exact and detailed inquiry one's aim is to get recorded steps at minimum time-interval. Then, by combining synthetically a great number of sequent stages, thus analytically distinguished, one may envisage a cinema picture of the advance of events in nature.

If one take snapshot records at very wide intervals, say near the beginning, in the central region, and at the end (so far) of the whole evolutionary process, our l may stand for the atom, our m for the amoeba, our n for man. In the specialized field of biological inquiry, all that lies below the living organism is excluded. But in a specialized branch of biochemical research the aim is to ascertain whether, under laboratory conditions, there can be traced an evolutionary passage from the not-living to the

living. If l be the not-living and n the living, the task of the biochemist (or part of his task) is to find the transitional steps which fall under m. The full sequence has not yet been found. What progress has been made in the seeking cannot here be summarized, since our aim is only to indicate the method of procedure; to emphasize the importance of recording next-to-next snapshots; and to show how, from a wide array of such records, a cinema picture may be constructed.

Mental Evolution.—The biologist and the biochemist tell us what happens when relations of the physical kind are in being. The specific "modes" of relatedness differ at different stages of the onward passage of events in evolutionary progress—atomic, molecular, and organic. Such difference as is in evidence, for example, in the living as contrasted with the not-living, must be duly formulated and loyally accepted. The canon of scientific interpretation runs: Given such and such modes of relatedness; such and such is the course of events.

In mental evolution relations of a different *kind*—relations other than physical or physiological, but none the less natural relations—must receive full consideration, and must be correlated with such physical relations as are judged to be co-present. But just as there are ascending modes of physical and physiological relatedness so are there ascending modes of mental relatedness. When this or that higher mode is in being, the course of events differs from that which is observed when the mode of relatedness has not come into being in evolutionary progress.

That which may be inferred from observation is still interpretable in terms of l, m and n, which now carry two-fold import, both physical and mental. In our own current experience, complex as this is, the aim of psychological analysis is to get as near as one can to next-to-next steps. But, under wide spacing, if l be the life-mind stage of an amoeba, m that of a rabbit, n that of a man, one should not interpret m in terms of n, which is more highly evolved; nor should one interpret m in terms of l—or in these terms *only*—because what gives to m its evolutionary status comprises *more than* is comprised under l. One should take m as one finds it at its own level. Thus one may say (a) in mental and in (b) physical regard (which provides for energy changes): Given such and such mode of relatedness extrinsic or intrinsic; such and such is the course of events in this or that instance of l, m or n. The same method of interpretation is applicable throughout nature. There is no privileged field of natural events wherein its writ does not run.

Restricted Evolution.—It remains briefly to indicate the cardinal claim of those who advocate a restricted use of the word "evolution." This claim is that a concept of *agency*, as efficient cause, is imperatively demanded when one passes the mechanical world of the not-living to the purposive realm of the living. On this all other claims hinge. A further claim—that here in focus—is that only when Life enters into, possesses, organizes and utilizes a physical cluster of events, is there evolution in that sense to which, as they urge, it should be restricted. There is, it is said, nothing in common, between cosmic or physical evolution, so called, and the uplifting activity of Mind disclosed in biological evolution. This may therefore, in elliptical phrase, be spoken of as Creative—more strictly as implying creative activity.

Here the question arises: Is treatment in terms of creative activity—thus restricted to the purposive realm of the living—scientific or metaphysical? The answer turns on definitions. Some so characterize the domain of science as to exclude from its purview the concept of activity as efficient cause. Others urge that it must be included in biology. Opinions differ. That of M. Bergson may here be cited. "La philosophie" he says, "devra donc suivre la science, pour superposer à la vérité scientifique une connaissance d'un autre genre, qu'on pourra appeler métaphysique." In science, he tells us, we are "dealing only with the evolved, which is a result, and not with evolution itself, which is the act by which the result is obtained.

It seems, then, we must take into consideration (1) an observable course of natural events; (2) an interpretation of these events in terms of relations, intrinsic and extrinsic; (3) an explanation of some of these events in terms of agency and act. Fully admitting that under the third heading an important philosophical problem falls for discussion, one may hold that those who impose any restriction of the range of efficient causality must argue their case at the bar of philosophy. In the foregoing sections the field covered by the first and second heading has been selected as the universe of discourse. As we have seen there is, under these headings, ample provision for mental relations in all their ascending modes, and therefore for mental evolution. But it should be realized that for those who use the word "evolution" in the restricted sense, mental evolution implies far more than this. It implies Life or Mind as the efficient cause of the course of events in living creatures. But even if some such philosophical implication be accepted—or preferably one less restricted in scope—the interpretation of all natural events in relational terms must still be the aim of the man of science in his detailed investigations. (*See* ANIMAL BEHAVIOUR; PSYCHOLOGY, COMPARATIVE.) (C. LL. M.)

EVOLUTIONARY ETHICS. There is no warrant for calling animals moral agents, though a few highly endowed types, such as dog and horse, which have become man's partners, may have some glimpse of the practical meaning of responsibility. Cases are known where an animal's natural reaction is inhibited, apparently because of previously established habits, possibly in some cases because ideas are beginning to emerge. But if a truly ethical action implies control in reference to a moral ideal, even those who are inclined to be generous to animals must allow that this is practically man's prerogative. Animals have behaviour, which hardly ever touches the level of conduct; man has always the possibility of conduct, though he often subsides into mere behaviour.

There are among animals many illustrations of what may be called the raw materials of morals. Thus, they are devoted to their offspring, sympathetic to their kindred, affectionate to their mates, self-subordinating in their community, courageous beyond praise. Many a mother animal, such as a stoat, will defend her offspring to the death. A male hornbill will wear himself to a skeleton in foraging for his brooding mate, imprisoned in a hole in a tree. A male baboon in a retreating troup will return in the teeth of danger to rescue a youngster accidentally left behind. Animals may not be ethical, but they are often virtuous. Many animals are faithfully monogamous, as in the case of ravens, eagles, cranes, swans, rhinoceros, oryx antelope, white whale, and orang. When higher animals act in concert, as when beavers cut a canal, or monkeys make a raid, or pelicans combine in fishing, or wolves hunt in a pack in winter, there is some degree of controlled self-subordination, which almost sounds the ethical note; and there are many instances of impulsive mutual aid beyond the bounds of the habituated and the instinctive. No one dreams of calling a plant altruistic because much of its energy is devoted to filling the seeds with nutritive legacy, and one must be restrained in one's appreciation of the instinctive other-regarding activities of ants and bees. Among some ants it is instinctive on the part of a well-fed individual to give food to a hungry beggar of the same species, and though we may agree with those who maintain that conscious kin-sympathy was at work in the racial establishment of that instinct, and that some awareness still remains, we would for our present purpose evade the difficulty by looking for evidence of good feeling among animals that illustrate an intelligent or a predominantly intelligent mode of life. Among mammals, for instance, there are many cases of behaviour that expresses not self-gratification, but devotion to the welfare of others.

For man there is evolutionary interest in these springs of sympathy and courage among animals, for he must have inherited impulses of this type from his pre-human ancestors. Man cannot be a moral Melchisedec, "without descent," and we look among the higher animals for illustrations of the fine strands of kindness, affection, self-subordination, loyalty, courage and control, which were afterwards woven into a distinctively human pattern. Regarding man as a new synthesis, making all things new, we willingly admit that he did not simply carry on and raise to a higher power the kin-sympathy, let us say, of the wolf; for evolution does not proceed in this simple fashion. But our point is

that there must have been definite pre-human strands which were transformed in the new synthesis of man.

The evolutionist question thus becomes: What was there in the early Hominoids to foster further progress in the direction of the raw materials of goodness? An answer cannot as yet be much more than groping. The ancestors of Homo supposedly diverged from a big-brained anthropoid stock of social disposition which had served a long arboreal apprenticeship. About the Miocene time, when the Himalayas were uplifted and the great forests began to shrink, the ancestors of tentative men were forced into a terrestrial environment and were subjected to sifting by predatory competitors from whom they had been previously in some measure isolated by their arboreal habits. Thus we picture the ancestors of men descending to terra firma, with more brains than brawn, with little chance against the large beasts of prey except by outwitting them, and with predispositions towards gentleness which had been engendered in part by the prolonged infancy with its appealing helplessness. Such pre-men, no doubt in obedience to their engrained promptings in favour of mutual aid and sociality, found safety in uniting their families into simple societies. For isolated human families the struggle for existence would be too keen when they ventured beyond the sanctuary of the trees; and thus there probably arose a self-preservative linkage of families, perhaps a million years ago. The fallacy must be avoided of supposing that our ancestors combined their families because they foresaw possible advantages, for this is not the way in which unsophisticated evolution works. They obeyed their social promptings and then discovered, more or less dimly at first, that there was a new strength in their old weakness. The experiments in society-making would give man a firmer foothold in the struggle for existence, and variations in the direction of increased sociality would tend to survive. Precious individuals, such as the pioneer artists and thinkers, would have a chance to survive under the society aegis; permanent products with their useful and educative enregistrations would increase; life would be more secure for adventurous children whose new departures form an important part of the raw materials of evolution, and the growth of tradition would be helped by the increasing care of the aged. Too often, in the things pertaining to man, the evolutionist relapses into creationism, trying to make faculties out of nothing; our point is that we must in our reconstruction make the most of the pre-human strands and of the cradle-influences of early experiments in society-forming.

But here it is necessary to introduce a saving-clause which expresses the divergence of the modern from the Spencerian outlook. As a convinced Lamarckian, Spencer believed that qualities directly induced by new functions and surroundings may be added to the racial repertory by hereditary entailment, and that they may be cumulatively increased by contributions made by individual parents. To many biological evolutionists this possibility appears unproven and even improbable.

MAN, THE NEW SYNTHESIS

The evolution of moral qualities may be divided into epochs. First, there was the pre-human period, marked by the rise and progress of parental affection, kin-sympathy, courage, self-subordination, and other primary virtues. Second, in the early ages of tentative men, hominoid rather than homines, there was a re-definition and re-thrilling of the moral fibres under the influence of the new synthesis or mutation—Man. With reason and language and consciousness of history both past and possible, there must have been a re-tuning of the moral nature. Third, there was the period of primitive societies, still small and simple, when social inter-relations began to have their subjective effect, when social claims began to transcend or to thwart those of the family and the individual, and when the social shield began to shelter variants who would have had difficulty in surviving in the isolated family. The fourth period is especially marked by the growth of the extra-organismal heritage—the moral tradition, the moralising institutions, the morality enregistered in literature and art, and everything in the nature of law. Only in this period did there begin the focussing of moral ideas and the formulation of moral standards. Only now was it possible to have a culture of goodness as a reward in itself. Moral ideals became self-conscious. As social complexities and inter-societary complications increased, a dilemma, previously not more than adumbrated, became poignant,—the dilemma between a social policy, more or less deliberately devised to secure survival, and the moral promptings intrinsic in our natural inheritance or extrinsic in our external heritage. Thus the desirable improvement of the human breed may conflict with our moral sentiments. Contrariwise our strong kin-sympathy may thwart charity organisation and multiply beggars. Moreover, the momentum of the social organisation into which we are born may baulk the realization of both social and individual ethical ideals. New moral problems have evolved with the growth of civilization, and even the individually good man may think too little of the state. Thus we are at present in the early days of an evolving social ethics.

Philosophical critics have exposed the difficulty of giving an account of the evolution of morals in terms of known biological and psychological factors; and that difficulty must be admitted by all who are not easygoing. There is a risk, however, of exaggerating the difficulty by failing to appreciate the subtlety of the evolutionist position. Thus it is not difficult to make game of the Darwinian theory of the evolution of the virtues, if one ignores such points as the following, (*a*) that natural selection includes "reproductive" selection, favouring the more fertile variants, often the better parents, as well as "lethal" selection, which eliminates the relatively unfit to given conditions; (*b*) that the struggle for existence, as Darwin emphasized, includes all the endeavours and reactions that organisms make against environing difficulties and limitations, the well-lined nest of the long-tailed tit, as well as the talons of the eagle; (*c*) that the living creature is not a passive item being sifted in a sieve, but an agent in its own evolution, as James Ward so clearly saw, playing for all it is worth its own hand of hereditary cards; (*d*) that the indispensable sifting, which results in the survival of certain variants on account of certain qualities, is in reference to an established system of Nature, often of extraordinary nicety; (*e*) that a variation not in itself such, in quality or in quantity, that it could be selected by the existing sieves, may be entailed for generations because it is correlated with other variations that have selection-value. There are well-known instances in the realm of organisms of characters which have had a cumulative increase, not because they themselves are of demonstrable utility, but because of a certain "organic momentum," the limit being that they do not prove positively disadvantageous.

In the evolution of morals there has been a continuous sifting of variations in man's sympathy, affection, courage, and control-power, and the sifting process has changed from crude to subtle natural selection, and from rational to social selection, the big fact being that variations in certain directions tend towards not survival merely, but progress. For the animal, progress means greater fullness and freedom of life, marked by increased differentiation and integration, and with an associated emancipation of the mental aspect. For man, granting health and wealth, progress means approximation to an asymptotic ethical ideal, which includes a richer embodiment of the true, the beautiful and the good. Conduct that is controlled towards the ideal is good conduct. Its strands were spun in the animal, they were woven and transmuted in man, they have been sifted by many modes of selection,—natural and sexual, rational and social. The processes of variation and selection are still continuing, and, since retrogressions are easy, it is man's unending task to criticise his sieves and the ideals which form their mesh. It must be allowed by all that these ideals have been influenced not only by man's intrinsic moral nature and extrinsic moral heritage, but by even subtler factors, such as his philosophy and religion. Their validity and sanctity are not prejudiced by an account of their evolution; to anyone with imagination their imperativeness is enhanced by a disclosure of their indispensability in the ascent of man.

But those who seek to form a scientific picture of the evolution

of morals must give to two considerations more attention than they have hitherto received. The first, already referred to, is the necessity of trying to distinguish moral peculiarities that express germinal variations from moral peculiarities that are impressed as nurtural modifications. This is important since the biological facts are, in the writer's judgment, strongly in favour of the hereditary transmission of the former, and against the hereditary transmission of the latter, which may, however, affect the extra-organismal or social heritage. Secondly an inborn variation, say in control-power, sympathy, courage, veracity, may be the subject of selection; yet it may be that the moral quality which is oftenest selected or eliminated is *the degree of susceptibility* to the social heritage as expressed in moral customs and moral institutions of every sort. Thus it becomes urgent to secure the continuance of those factors that have in the past demonstrably bettered the extra-organismal heritage—such homely but supreme influences as the love between man and woman, the happy family, and the social solidarity induced by combination in noble endeavour. A continuance and development of these ameliorative influences, adjusted as need be, must be recognized as the practical side of the evolution of morals.

NATURE AND THE PHILOSOPHERS

But besides the evolution of morals, there arises the question of the ethics of evolution. If man is the present climax of a long process of organic evolution, it is natural to ask whether there is in the evolving system of animate Nature any guidance for his conduct, or any confirmation of his ideals. There has been much difference of opinion on this subject. Thus in a famous essay John Stuart Mill (1874) arraigned Nature for "recklessness," "cruelty," and indiscriminate frustration of man's efforts. To follow Nature, he said, would be "irrational" (Nature being such a wasteful bungler) and "immoral," for "the course of natural phenomena is replete with everything which, when committed by human beings, is most worthy of abhorrence." Somewhat similar was the indictment of Nature in William James's essay, "Is Life worth living?" but his Manichaeism went even deeper. He arraigned Nature for "hideousness," "cruelty," and meaningless weather. "Visible nature is all plasticity and indifference—a moral multiverse, as one might call it, and not a moral universe. To such a harlot we owe no allegiance; with her as a whole we can establish no moral communion." In the pronouncements by these two philosophers there is no appreciation of the actual advancement of life which has been accomplished in organic evolution, no appreciation of the ubiquitous beauty and the almost universal healthfulness, no mention of the parental care, the mutual aid, the kin-sympathy that are so common, no discernment of the rewards of survival and success that have been given to the self-subordinating as generously as to the self-assertive. The fact is that the pictures of Nature drawn by John Stuart Mill and William James are out of perspective and off colour. They do not show a sufficiently intimate acquaintance with Nature as it actually is.

But this cannot be said of Huxley whose famous lecture on "Evolution and Ethics" pictures animate Nature as too much like a vast gladiatorial show, a Hobbesian warfare of each against all, a dismal cockpit, an inexorable struggle for existence, the result of which is merely the survival of the most suitable, not of the best in any sense. "Let us understand, once for all, that the ethical progress of society depends, not on imitating the cosmic process, still less in running away from it, but in combating it." It must be granted that Huxley was exposing the error that the survival of the fittest need mean more than the survival of those organisms that are best suited to the particular conditions of their life. The tapeworm is "fit" as well as the golden eagle which it inhabits; and the process of evolution may be retrogressive as well as progressive. Yet, on the whole, we submit, the process of organic evolution had been an integrative advance. It must be granted also that Huxley was making the point that animal life is not in the strict sense ethical, which every clear thinker allows. Yet there is one-sidedness in Huxley's picture, for it is not made clear that "the struggle for existence" is, as Darwin said, a formula covering all the answers-back that organisms make to environing difficulties and limitations, that it includes experiments in co-operation as well as in competition, in parental care as well as in predatory devices, in self-subordination as well as in self-assertion.

But turning from these arraignments we would advance a positive thesis that in the realm of organisms there are great evolutionary movements which correspond in their general trend with some of the best of those expressed in man's concept of progress. Living Nature is all for health; apart from parasites there is practically no disease in wild nature. Beauty is Nature's hall-mark of harmonious vigorous life; ugliness her stigma of dishonour, hardly seen except in those organisms that adopt the parasite's drifting life of ease. Even among animals there is a trend that makes against dull stupidity, so fatal to the giant saurians, and puts a premium on brains. Finally there is survival value among animals in other-regarding as well as in self-regarding endeavours. Good parents, good lovers, good kin do by no means lose their reward. Thus we deliberately advance the thesis that man's pursuit of the beautiful, the true, and the good, though transcending all biology, has its adumbrations in animate nature. *See* ETHICS; EVOLUTION; ANIMAL BEHAVIOUR; ANIMAL SOCIOLOGY.

EVORA, the capital of an administrative district in the province of Alemtejo, Portugal; 72 m. E. by S. of Lisbon, on the Casa Branca-Evora-Elvas railway. Pop. (1920) 16,148. Evora occupies a fertile valley enclosed by low hills. It is surrounded by ramparts flanked with towers, and is further defended by two forts. Evora is the see of an archbishop, and has several churches, convents and hospitals, barracks, a diocesan school and a museum. A university, founded in 1550, was abolished on the expulsion of the Jesuits in the 18th century. The cathedral, originally a Romanesque building erected 1186–1204, was restored in Gothic style about 1400; its richly decorated chancel was added in 1761. The church of São Francisco (1507–1525) is a good example of the blended Moorish and Gothic architecture known as Manoellian. The art gallery, formerly the archbishop's palace, contains a collection of Portuguese and early Flemish paintings. An ancient tower, and the so-called aqueduct of Sertorius (really dating from *c.* 1550), 9 m. long, have been partly demolished to make room for the market-square, in which one of the largest fairs in Portugal is held at midsummer. Both tower and aqueduct were long believed to have been of Roman origin, but are now known to have been constructed about 1540–1555 in the reign of John III., at the instance of an antiquary named Resende. The aqueduct was probably constructed on the site of the old Roman one. A small Roman temple is usually known as the temple of Diana, a name for which no valid authority exists. Evora is of little commercial importance, except as an agricultural centre, but its neighbourhood is famous for its mules and abounds in cork-woods; there are also mines of iron, copper, and asbestos and marble quarries.

Under its original name of *Ebora*, the city was from 80 to 72 B.C. the headquarters of Sertorius, and it long remained an important Roman military station. It was called *Liberalitas Juliae* on account of certain municipal privileges bestowed on it by Julius Caesar. Its bishopric, founded in the 5th century, was raised to an archbishopric in the 16th. In 712 Evora was conquered by the Moors, who named it *Jabura;* and it was only retaken in 1166. From 1663 to 1665 it was held by the Spaniards. In 1832 Dom Miguel, retreating before Dom Pedro, took refuge in Evora; and here was signed the convention of Evora, by which he was banished. (*See* PORTUGAL.)

ÉVREUX, a town of north-western France, capital of the department of Eure, 67 m. W.N.W. of Paris on the Ouest-État rail-

way to Cherbourg. Pop. (1926) 14,847. It stands on the slopes of the valley of the Iton. Vieil-Évreux (*Mediolanum Aulercorum*) was the capital of the Gallic tribe of the *Aulerci Eburovices* and a flourishing city during the Gallo-Roman period. Its bishopric dates from the 4th century. The first family of the counts of Évreux which is known was descended from an illegitimate son of Richard I., duke of Normandy, and became extinct in the male line with the death of Count William in 1118. The countship passed in right of Agnes, William's sister, wife of Simon de Montfort-l'Amaury (d. 1087) to the house of the lords of Montfort-l'Amaury. Amaury III. of Montfort ceded it in 1200 to King Philip Augustus. Philip the Fair presented it (1307) to his brother Louis, for whose benefit Philip the Long raised the countship of Évreux into a peerage of France (1317). Philip of Évreux, son of Louis, became king of Navarre by his marriage with Jeanne, daughter of Louis the Headstrong (Hutin), and their son Charles the Bad and their grandson Charles the Noble were also kings of Navarre. The latter ceded his countships of Évreux, Champagne and Brie to King Charles VI. (1404). In 1427 the countship of Évreux was bestowed by King Charles VII. on Sir John Stuart of Darnley (*c.* 1365–1429), the commander of his Scottish bodyguard, who in 1423 had received the seigniory of Aubigny and in Feb. 1427–28 was given the right to quarter the royal arms of France for his victories over the English (*see* Lady Elizabeth Cust, *Account of the Stuarts of Aubigny in France, 1422–1672*, 1891). On Stuart's death (before Orléans during an attack on an English convoy) the countship reverted to the crown. It was again temporarily alienated (1569–84) as an appanage for Francis, duke of Anjou, and in 1651 was finally made over to Frédéric Maurice de la Tour d'Auvergne, duke of Bouillon, in exchange for the principality of Sedan.

Évreux is the seat of a bishop. Part of the cathedral nave dates from the 11th century; the west façade is mostly late Renaissance. The elaborate north transept and portal are in the Flamboyant style; the choir is earlier Gothic. The Cardinal-bishop de la Balu built the octagonal central tower and the Lady chapel (15th century), which is remarkable for its stained glass. Two rose windows in the transepts and the carved wooden screens of the side chapels are masterpieces of 16th-century workmanship. The episcopal palace (15th century), adjoins the south side of the cathedral. An interesting 15th century belfry faces the modern town hall. The church of St. Taurin is Romanesque (14th century) and later. At Vieil-Évreux, 3½ m. S.E. of the town, the remains of a Roman theatre, a palace, baths and an aqueduct have been discovered; various finds are in the museum of Évreux. Évreux is the seat of a prefect, a court of assizes, of tribunals of first instance and commerce, a chamber of commerce and a board of trade arbitrators. The making of ticking, metal-founding and scientific glass-making are carried on.

EVZONES, members of rifle units in the Greek army, recruited from mountainous districts, and wearing a picturesque dress with wide skirt and tufted shoes. Their organization corresponds to that of a line infantry regiment. There are three regiments of Evzones in the Greek army.

EWALD, GEORG HEINRICH AUGUST VON (1803–1875), German Orientalist and theologian, was born on Nov. 16, 1803, at Göttingen, where his father was a linen-weaver. Educated at the university of his native town, he was made professor *extraordinarius* in philosophy and lecturer in Old Testament exegesis in 1827, professor *ordinarius* (in 1831) in philosophy, and in 1835 of Oriental languages. Having in 1837, along with six of his colleagues signed a formal protest against the action of King Ernst August (duke of Cumberland) in abolishing the liberal constitution of 1833, which had been granted to the Hanoverians by his predecessor William IV., he was expelled from the university. Early in 1838, however, Ewald received a call to Tübingen, and there for upwards of ten years he held a chair as professor *ordinarius*, first in philosophy and afterwards, from 1841, in theology. To this period belong some of his most important works, and also the commencement of his bitter feud with F. C. Baur and the Tübingen school. In 1847 he returned to Göttingen, the liberal constitution having been restored. But the chief crisis in his life arose out of the political events of 1866. His loyalty to King George (son of Ernst August) would not permit him to take the oath of allegiance to the victorious king of Prussia, and he was therefore placed on the retired list, though with his full salary as pension. The violent tone of some of his printed manifestoes about this time, especially of his *Lob des Königs u. des Volkes*, led to his being deprived of the *venia legendi* (1868) and also to a criminal process, which, however, resulted in his acquittal (May 1869). Then, and on two subsequent occasions, he was returned by the city of Hanover as a member of the North German and German parliaments. In June 1874 he was found guilty of a libel on Prince Bismarck. He died on May 4, 1875.

As a teacher Ewald had a great power of kindling enthusiasm. His *Hebrew Grammar* marked a new era in biblical philology; and as an exegete and biblical critic no less than as a grammarian he has left his abiding mark. His *Geschichte des Volkes Israël*, the result of 30 years' labour, was epoch-making in that branch of research. Taking up the idea of a divine education of the human race, which Lessing and Herder had made so familiar to the modern mind, and firmly believing that to each of the leading nations of antiquity a special task had been assigned, Ewald felt no difficulty about Israel's place in universal history. The history of Israel, according to him, is simply the history of the manner in which the one true religion came into the possession of man. The historical interval between the exodus and the appearance of Christ is treated as dividing itself into the periods of Moses, David and Ezra, and indicated by the successive names by which the chosen people were called—Hebrews, Israelites, Jews.

His chief works are:—*Die Composition der Genesis kritisch untersucht* (1823), an acute and able attempt to account for the use of the two names of God without recourse to the document-hypothesis; *Kritische Grammatik der hebr. Sprache* (1827) which became in 1844 the *Ausführliches Lehrbuch der hebr. Sprache* (8th ed., 1870, Eng. trs. 1836); *Hebr. Sprachlehre für Anfänger* (4th ed., 1874); *Commentarius in Apocalypsin Johannis* (1828); *Abhandlungen zur biblischen u. orientalischen Literatur* (1832); *Grammatica critica linguae Arabicae* (1831–33); *Die poetischen Bücher des alten Bundes* (1835–37); *Die Propheten des alten Bundes* (1840–41, Eng. trs. 1875–81); *Geschichte des Volkes Israël* (1843–59, partial Eng. trs. 1867–74); *Alterthümer Israels* (1848, Eng. trs. 1876); *Die drei ersten Evangelien übersetzt u. erklärt* (1850); *Über das äthiopische Buch Henoch* (1854); *Die Sendschreiben des Apostels Paulus übersetzt u. erklärt* (1857); *Die Johanneischen Schriften übersetzt u. erklärt* (1861–62); *Über das vierte Esrabuch* (1863); *Sieben Sendschreiben des neuen Bundes* (1870); *Das Sendschreiben an die Hebräer u. Jakobos' Rundschreiben* (1870); *Die Lehre der Bibel von Gott* (1871–75); *Jahrbücher der biblischen Wissenschaft* (12 vols., 1849–65).

EWALD, JOHANNES (1743–1781), the greatest lyric poet of Denmark, was born at Copenhagen on Nov. 18, 1743, the son of a chaplain. He studied at Schleswig and Copenhagen. At 15 he fell in love with Arense Hulegaard, and in order to distinguish himself enlisted in the Prussian army. After a series of extraordinary adventures in the Seven Years' War, he deserted to the Austrians, where from being drummer he rose to being sergeant. In 1760 he deserted again, returned to Denmark and in 1762 passed his final examination. About the same time Arense married another man, and Ewald never recovered from the disappointment.

On the death of Frederick V., Ewald published in 1766 three *Elegies* over the dead king; one of these is a veritable masterpiece. But his dramatic poem *Adam og Eva* (Adam and Eve), by far the finest imaginative work produced in Denmark up to that time, was rejected by the Society of Arts in 1767 and was not published until 1769. In 1770 Ewald produced *Rolf Krage*, the first original Danish tragedy. During the next ten years he produced one brilliant work after another:—*De brutale Klappers* (The Brutal Clappers, 1771), a tragi-comedy or parody satirizing the dispute then raging between the critics and the manager of the Royal Theatre; *Harlequin Patriot* (1772), a comedy satirizing the passion for political scribbling created by Struensee's introduction of the liberty of the press; *Pebersvendene* (Old Bachelors, 1773), a prose comedy. In 1771 he had already collected some of his lyrical poems under the title of *Adskilligt af Johannes Ewald* (Miscellanies). In 1774 appeared the heroic opera of

Balder's Död (Balder's Death), and in 1779 the finest of his works, the lyrical drama *Fiskerne* (The Fishers), which contains the Danish National Song, "King Christian stood by the high Mast," his most famous lyric. In the two poems last mentioned, however, Ewald passed beyond contemporary taste, and these great works, the pride of Danish literature, were coldly received. In 1775 he founded the Danish Literary Society. But the poet's health had broken; when he was writing *Rolf Krage* he was already consumptive. He embittered his existence by the recklessness of his private life, and finally, through a fall from a horse, he became a complete invalid. His last ten years were full of acute suffering, his family neglected him, and few of his friends showed him any kindness. In 1774 he was placed in the house of an inspector of fisheries at Rungsted, where he fell in love with Anna Hedevig Jacobsen, the daughter of the house. Marriage with her was prevented by his family, who removed him to their own rough keeping near Kronborg. He insisted on returning to Copenhagen in 1777, where he wrote *Fiskerne* with his imagination full of the familiar shore at Hornbaek, near Rungsted. He died on March 17, 1781, recognized at the last as the greatest national poet. Among his papers were found fragments of three dramas, two on old Scandinavian subjects, entitled *Frode* and *Helgo*, and the third a tragedy on the story of *Hamlet*, which he meant to treat in a way wholly distinct from Shakespeare's.

In point of time Ewald preceded all the generations of innovators in European poetry. He was born six years earlier than Goethe and Alfieri, 16 years before Schiller, nine years before André Chénier, and 27 years earlier than Wordsworth, but he did for Denmark what each of these poets did for his own country. Ewald found Danish literature given over to tasteless rhetoric, and without art or vigour. He introduced vivacity of style, freshness and brevity of form, and an imaginative study of nature. He was the first to call the attention of the Scandinavian peoples to the treasuries of their ancient history and mythology, and to suggest the use of these in imaginative writing. His dramas, which had an immense influence on the Danish stage, are now chiefly of antiquarian interest, with the exception of "The Fishers," a work that must always live as a great national poem.

The first collected edition of Ewald's works appeared in 4 vols. (1780–84). The latest edition by K. Brix and V. Kuhr (6 vols., Copenhagen, 1914–24) contains his autobiography, a Danish classic. The best biographies of him are those by C. Molbech (1831), Hammerich (1860) and Andreas Dolleris (1900). *See* also H. Brix, *Johannes Ewald* (1913).

EWART, WILLIAM (1798–1869), English politician, was born in Liverpool on May 1, 1798, and died at Broadleas, near Devizes, on Jan. 23, 1869. Ewart carried through parliament in 1834 a bill for the abolition of hanging in chains, and in 1837 he secured the passage of an act abolishing capital punishment for cattle-stealing and other offences. In 1850 he carried a bill for establishing free libraries supported out of the rates, and in 1864 for legalizing the use of the metric system of weights and measures. He advocated the abolition of capital punishment and on his motion in 1864 a select committee was appointed to consider the subject.

EWE (ā-wā'), a long-headed patrilineal people living in Togo and the Gold Coast, having immigrated from the north-east. They are organized in small kingdoms, the king is elected from among the chiefs and assisted by a council of notables. They have the extended family, holding property in common, and allowing individual ownership of personal possessions. Inheritance passes to the maternal uncle, but different kinds of movable property pass to the paternal uncle and the children. They are husbandmen and animists, and practice divination and the ordeal.

See Spieth, *Die Ewe Stämme* (1906).

EWING, SIR JAMES ALFRED (1855–), Scottish physicist, was born at Dundee on March 27, 1855. He studied at Edinburgh and held successively the following appointments: Professor of mechanical engineering, University of Tokyo (1878–83); professor of engineering, University College, Dundee (1883–90); professor of mechanism and applied mechanics, King's college, Cambridge (1890–1903), director of naval education to the British Admiralty (1903–16); and principal and vice-chancellor of the University of Edinburgh from 1916.

Ewing's work on the magnetic properties of iron, steel and other metals is noteworthy. He modified Weber's theory of induced magnetism, and constructed a magnetic model which behaved in accordance with his theory; he also observed the phenomenon which he named "hysteresis" (*q.v.*, *see* also MAGNETISM). The Royal Society awarded him their Royal medal for this work in 1895. He is the author of a number of papers on thermoelectric properties of metals, on the effects of stress and magnetization on the thermoelectric properties of iron, on the crystalline structure of metals (in conjunction with Rosenhain), and on seismology. He invented an extensometer, a hysteresis tester, a permeability bridge, and other apparatus for magnetic testing.

Ewing was a member of the explosives committee and of the Ordnance Research board; from 1914–1917, he was in charge of the department of the Admiralty dealing with cipher. He is a member of a number of learned societies and has been awarded medals and honorary degrees. In 1911 he was knighted.

Ewing wrote *A Treatise on Earthquake Measurements* (1883), *The Steam Engine and other Heat Engines* (1898), *Magnetic Induction in Iron and other metals* (1892, etc.), *Strength of Materials* (1899, etc.), *Thermodynamics for Engineers* (1920), *The Mechanical Production of Cold* (1921).

EWING, JULIANA HORATIA ORR (1841–1885), English writer of books for children, daughter of the Rev. Alfred Gatty and of Margaret Gatty (*q.v.*), was born at Ecclesfield, Yorkshire, in 1841. One of a large family, she was accustomed to act as nursery story-teller to her brothers and sisters, and her brother Alfred Scott Gatty provided music to accompany her plays. Many of her stories appeared in *Aunt Judy's Magazine*, which her mother started in 1866. In 1867 she married Major Alexander Ewing, the composer of the well-known hymn "Jerusalem the Golden." From this time until her death (May 13, 1885), Mrs. Ewing produced a number of charming children's stories. The best of these are: *The Brownies* (1870), *A Flat-Iron for a Farthing* (1873), *Lob-lie-by the Fire* (1874), *The Story of a Short Life* (1885) and *Jackanapes* (1884), which is a classic. Simple and unaffected in style, and sound and wholesome in matter, with quiet touches of humour and bright sketches of scenery and character, Mrs. Ewing's best stories have never been surpassed in the style of literature to which they belong.

EWING, THOMAS (1789–1871), American lawyer and statesman, was born near the present West Liberty (W.Va.), Dec. 28, 1789. His father, George Ewing, settled at Lancaster, Fairfield county, O., in 1792. Thomas graduated from Ohio university, Athens, O., in 1815, and in Aug. 1816 was admitted to the bar at Lancaster. He was a Whig member of the United States Senate 1831–37, and took a prominent part in the legislative struggle over the United States bank, whose rechartering he favoured. In March 1841 he became secretary of the treasury in President Harrison's cabinet. When, however, after President Tyler's accession, the relations between the president and the Whig party became strained, he retired (Sept. 1841). From March 1849 to July 1850 he was a member of President Taylor's cabinet as the first secretary of the newly established department of the interior. He thoroughly organized the department, and advocated the construction by Government aid of a railroad to the Pacific coast. In 1850–51 he filled the unexpired term of Thomas Corwin in the U.S. Senate, opposing Clay's compromise measures and advocating the abolition of slavery in the district of Columbia. He was a delegate to the Peace congress in 1861, and a loyal supporter of President Lincoln's war policy. He died at Lancaster, O., on Oct. 26, 1871.

EXAMINATIONS. An "examination" is primarily a test of the "capacity" of individuals. The individuals are generally young people or children; their "capacity" is their power to respond to a stimulus provided by the examiner. The character of their responses is measured by the examiner against a standard of achievement usually determined by the type of the examination; when, however, an examination is used to select individuals for a limited number of places it becomes competitive, as in most scholarship and civil service examinations. Success is commonly indicated

by an "award" which serves thereafter as a convenient label, a summary of the "capacity" of the individual. Frequently the "award" carries with it certain rights to further education at the expense of a public or corporate body (scholarship at school or university) to practise teaching or medicine or to enter the State service (civil servant). Sometimes the "award" confers, in addition, membership of a corporate body of practitioners who monopolize certain services or professions (law, medicine, etc.). Hitherto, in England and Europe generally, the methods employed to these ends have been largely founded on written and oral tests in certain specific subjects. The example of the United States of America (*see* that section), however, in which the application of intelligence tests to examinations has been practised on a large scale, cannot be ignored. In fact, it is already in limited use in Great Britain.

HISTORY

The oldest known system of examinations was that used in China for the selection of officers for the public service (*c.* 1115 B.C.). The examinations of western countries originated in the universities of the middle ages. The first universities of Europe consisted of corporations of teachers and of students. The monopolistic tendency of their system of examinations has dominated subsequent developments.

The object of the universities was to teach; and to the three customary classes of gild-members, apprentices, companions and masters, corresponded roughly the *scholar,* the *bachelor* or pupil-teacher, and the *master* or *doctor* (two terms at first equivalent). The universities being under the same religious authority, the permission to teach granted by one university was valid for all. (*See* UNIVERSITIES.)

Bologna.—The earliest university examinations of which a description is available were those in civil and in canon law, held at Bologna during a period subsequent to 1219. The student was admitted without examination as bachelor after from four to six years' study, and after from six to eight years' study became qualified as a candidate for the doctorate. The doctoral examination at Bologna during the 13th to 14th centuries consisted of a private examination which was the real test, and a public ceremonial (*conventus*). On the morning of the examination the candidate was assigned two passages in the civil or canon law, which he retired to his house to study, possibly with the aid of the presenting doctor. Later in the day he gave an exposition of these set passages and was examined by two of the doctors appointed by the college. Other doctors might then put supplementary questions on law arising out of the passages, or might suggest objections to his answers. The fate of the candidate was determined by ballot by a majority vote. The successful candidate, who received the title of licentiate, after payment of a heavy fee and other expenses proceeded to the *conventus.* This public test comprised the delivery of a speech, and the defence of a thesis on some point of law selected by the candidate, against opponents chosen from among the students. Success was followed by the bestowal of a "licence to teach" by the authority of the pope in the name of the Trinity.

Paris.—In Paris a more complicated system had developed by A.D. 1300. In the faculty of arts there were three degrees—the baccalaureate, the licentiateship and the mastership. At a preliminary test or "responsions" the candidate had to dispute in grammar or logic with a master. Certificates of residence and of attendance at courses in certain subjects had to be presented, and the candidate was tested in the contents of his prescribed books. If successful, he was then admitted to maintain a thesis against an opponent, and as bachelor was permitted to give "cursory" lectures. Having reached a prescribed age, and five or six years after his matriculation, a bachelor might take the next examination. This test began with an examination in private by the chancellor and four examiners, a scrutiny of records of study and later a public test before the faculty. The names of successful candidates were sent to the chancellor in batches of eight or more arranged in order of merit. Subsequently the candidate maintained, in public, a thesis on a subject chosen by himself and was submitted to a purely formal public examination. Success was followed by the receipt from the chancellor of the licence to teach in the faculty of arts. Some six months later the licentiate took part in a peculiarly solemn disputation known as his "Vespers," gave a formal inaugural lecture before the faculty and was "incepted" into the mastership.

In the mediaeval examination systems lie the origins of many current university practices: certificates of previous study and good conduct, preparation of set-books, questions on matter not specially prepared, division of the test into various parts, orders of merit, payment of fees, the presentation of a dissertation, and the defence and publication of a thesis. Occasionally the system was abused, yet at its best it probably served its function to test would-be teachers. Written and practical examinations came into use as university teaching broadened in scope.

British Universities.—At Oxford (*q.v.*), in the middle ages, examinations were apparently confined to "disputations." Laud (1636–38) introduced definite examinations for M.A. and B.A., but it is doubtful how far they were enforced. In the 18th century "the studies fell into an abject state." Important reforms were introduced in 1800 when, by statute, distinctions were first awarded to the ablest candidates for the bachelor's degree. In 1830, in addition to the pass examinations, honours examinations were set up; the successful candidates were more rigorously tested and were divided into four classes. By the statutes of 1849 and 1859 an intermediate "Moderations" examination was instituted between the preliminary examination called "Responsions" or "Smalls" and the final examination. Long before the 19th century the B.A. had become the recognized culmination of a long course of study, and in 1807 the examination for M.A. was abolished. A holder of the B.A. degree now proceeds to the M.A. degree on the payment of fees. Respersions have now been superseded by the School certificate which a candidate passes before entrance. At Cambridge development followed similar lines and there, also, the M.A. is a mere formality. During the 18th century the "reputation of Cambridge" was established "as a School of Mathematical Science," but the standard of the final honours examination, the "tripos," did not become generally high till 1840. The preliminary examination, the Previous, or "Little-go," now superseded by the School certificate, leads directly to the triposes or to the numerous special subjects necessary for a pass degree (B.A.), from which a candidate must choose three principal and three subsidiary. Nearly all the triposes have been divided into two parts, of which the second is not always obligatory to obtain a degree. British degree examinations were thus developed by the universities and were normally open only to members of the universities in residence. In 1858 the University of London, where examinations had been hitherto confined to students in affiliated colleges, threw open its examinations to all comers who could produce a nominal certificate of good conduct, and the university became an examining body pure and simple. Candidates wrote answers to printed questions at examination centres in London, elsewhere in the British Isles and also in the British empire. Candidates for a bachelor's degree took three examinations (matriculation, intermediate and final) and proceeded to higher degrees by subsequent examination. In 1900 the university became hybrid and added to the former system of "external" examinations a parallel system of "internal" examinations for members of constituent colleges of the university. Women were recognized as eligible for examination at London in 1878, at Cambridge in 1881, at Oxford in 1884. They are now eligible for degrees at all the universities. When, in 1880, the Federal University of Victoria was formed, the examinations were confined to internal students and the practice has been followed in the case of the newer foundations of Manchester, Liverpool, Leeds (formerly constituent colleges of Victoria university), as well as those of more recent foundation.

In Scottish universities the B.A. has become extinct, and the M.A., awarded on the results of examinations, is the first degree in the faculty of arts. Formerly the M.A. was taken in many subjects, now the final examination can be taken in honours in one or two.

In Trinity college, Dublin, degrees were also obtainable by external students; but on the foundation of the Royal University of Ireland in 1880, the earlier London model was followed of making the university a purely examining body. In 1908 the R.U.I. was replaced by the National University of Ireland and by Queen's university, Belfast. To-day all examinations in Irish universities are closed to external students, except that at Dublin university (as the former Trinity college is now called); exemption from the regulations may be given in very exceptional cases.

Since the growth of university studies, the number of examinations in British and Irish universities has greatly multiplied, and the calendars and regulations now form bulky documents which prescribe the conditions under which degrees can be obtained. The most important new degree is the doctorate of philosophy (Ph.D.) which is awarded on a thesis on any academic subject approved by the faculty concerned.

French Universities.—In France the *baccalauréat,* which has also become a school-leaving certificate (*see* below) is the entrance to the university. It leads to the *licence* in arts, science or law. A point to note in the French examinations, especially the higher ones, is that in many cases the subjects are now often taken separately. Thus the *licence* in arts or science is granted to the student obtaining four subjects selected by him out of a large number, which he can, if he prefers, take one at a time. The *doctorat* in arts requires the presentation of these two theses, which often involve years of strenuous work. If these are accepted, they are followed by a public *soutenance* (maintenance) of his thesis by the candidate. The possession of the *doctorat* is an indispensable qualification for full professorship.

In science a candidate for the doctorate submits two theses, or else one thesis and undergoes an oral examination; in law, a thesis and two oral examinations are required. In medicine there is no *licence,* but six examinations are to be passed, and a thesis submitted. A special *doctorat d'Université,* awarded on a thesis and an oral examination, has been instituted for foreign students of graduate standing, and *diplômes d'études supérieures* are awarded on subjects such as philosophy, history, etc., and generally taken by persons intending to enter the teaching profession.

German Universities.—Students enter the university by passing the "Abiturienten" examination (also known as *reifere Prüfung*) at the age of eighteen. For his doctor's examination the student has to present a thesis. If this is accepted, he has to submit to a public oral examination on his principal subject (*Hauptfach*) and on two or more collateral subjects (*Nebenfächer*). He may then give outside lectures in the university, as a *Privatdozent.* But to become a full university professor, he must have a more advanced thesis (*Habilitationsschrift*) accepted, and give two specimen lectures, but these latter proceedings have become largely a formality.

In university examinations, most of the other European countries follow closely the lines of the French or German model.

PROFESSIONAL EXAMINATIONS

Teaching.—*Great Britain.* Elementary teachers pass examinations in knowledge and teaching proficiency, hitherto conducted by the Board of Education, but now being transferred to the universities. Teachers, however, who follow a four years' course in a university take the teaching diplomas of the university concerned. There is no official compulsion for teachers in secondary schools to be trained, but an increasing number of graduates are taking university courses of training, especially women. In fact, in girls' schools, training is rapidly becoming a sine qua non.

France. Elementary teachers have to pass a State examination for entrance into a training college as well as a leaving examination at the end of the year; the latter includes a test in teaching proficiency. Teachers in the higher classes of secondary State schools (Lycées) have to pass an examination called the *agrégation,* comprising a severe written and oral test. Ordinary teachers in the schools need only have the *licence* or *diplôme d'études supérieures.*

Germany. Elementary teachers have to pass the ordinary State examinations, academic and professional. Secondary teachers are obliged to attend a university for three years. The Ph.D. is optional, but they must take the State examination and become full teachers only after two years' probation.

Law and Medicine.—(*See* LEGAL EDUCATION; MEDICAL EDUCATION.)

Other Professions.—A complicated system of professional examination by professional bodies was largely developed in Great Britain during the 19th century. Many of these bodies even conducted the preliminary entrance examinations, but fortunately, in many cases, they have adopted in their place certain accredited examinations like the "locals" of the universities or the examinations of the College of Preceptors. The following are some of the more important subjects (the professional body concerned being given in brackets): Accountancy [Institute of Chartered Accountants and Society of Accountants and Auditors]; actuarial work [Institute of Actuaries]; music [Royal Academy of Music, Royal College of Music, Trinity College of Music, Royal College of Organists, and the Incorporated Society of Musicians]; pharmacy [Pharmaceutical Society]; plumbing [the Plumbers' Company]; surveying [Surveyors' Institution]; veterinary medicine [Royal College of Veterinary Surgeons]; technical subjects, *e.g.,* cotton-spinning, dyeing, motor manufacture [City and Guilds of London Institute]; architecture [Royal Institute of British Architects]; engineering [Institutions of Civil Engineers, of Mechanical Engineers, and of Electrical Engineers]; commercial subjects, shorthand [the Society of Arts and London Chamber of Commerce]. (*See* COMMERCIAL EDUCATION.)

SCHOOL-LEAVING EXAMINATIONS

Great Britain.—A somewhat similar multiplicity of examinations formerly prevailed in the sphere of secondary education. Pupils, even those of ten years of age, were subjected to examination. All such intermediate examinations, with the exception of the junior locals taken mainly by private schools, have been abolished as far as the universities are concerned, and since 1917, the secondary school examination council has been steadily engaged in a continuous audit of school examinations, in the way of standardizing the papers set by the different universities, co-ordinating methods of marking, etc. State-recognized examinations are now confined to the school-leaving certificate (a higher standard in which, under certain conditions, qualifies for the matriculation or entrance to the university), and the higher school certificate, taken in a more limited number of subjects. The former is generally taken at the age of 16 or 17; the latter at the age of 18 or 19. (For further details *see* below.) In Wales, Scotland, Northern Ireland, and the Irish Free State, similar examinations are to be found.

France.—In France the *baccalauréat,* after the reform of 1902 (*see* EDUCATION: *France*) consisted of four different sections: Classical; Latin-Modern Languages; Latin-Science; Modern Languages-Science. However, since the recent reforms of M. Bérard, slightly modified by M. Herriot, it has been reduced to two—classical or modern. The examination is divided, as before, into two parts, and the second deals mainly either with philosophy or with science, including mathematics. It is taken a year later than the first part. Each part further consists of two sections, a written and an oral one, and the pupil's school record is taken into account in the final award in each case.

Germany.—In Germany (of which Prussia may be taken as the best example) the school-leaving examination which also, as we have seen, qualifies for entrance to the university, is the *Abiturienten* examination. It varies in subject according to the type of school to which it applies, whether it is fully classical, half classical or modern. In German education a point to note is that the teachers themselves take part in the examination (a very desirable factor). The usual age at which the examination is taken is 17 to 18. There is also a *Mittlere-reife-prüfung,* taken at the age of 16, which gains admission to certain professions; pupils in the first grade schools mentioned above are automatically awarded the certificate on being promoted to the *Ober-secunda* class, of which the normal age is 16.

Leaving examinations in other European countries largely resemble those of either France or Germany.

ELEMENTARY EXAMINATIONS

For many years examinations of all the pupils in each public elementary school in Great Britain were conducted by the Government inspectors. The system lasted from 1862 till 1895 and was known as "payment by results" (*see* ELEMENTARY EDUCATION). The principal reason for its abolition was the cramping effect it had alike on teachers and taught. Central schools, so far, have had no leaving examination, though one has been proposed by the commission on the education of the adolescent.

In France there is an elementary leaving certificate with written and oral tests called the *certificat d'études primaires*, generally supposed to be passed at the age of 12, but often taken earlier. There is a leaving certificate for the higher primary school, which also serves for entrance into the training colleges.

COMPETITIVE EXAMINATIONS

In Great Britain, competitive examinations may vary from County Council scholarships awarded at the age of 11 to scholarships at the public schools, or at the universities. They are also used for entrance to all grades of the civil service—from sorters in the post office to first-class clerks in the Foreign Office. The award depends, not on reaching a certain standard of attainment, but on the number of scholarships or posts open to candidates. The first competitive examination was instituted in 1885 for entrance to Woolwich academy and the system was generally adopted for the civil service in 1870, in order to do away with the widespread abuses connected with the nomination of unfit persons. The same principle was adopted after the World War when a large number of temporarily employed ex-soldiers were allowed to qualify for permanent service by passing certain specific examinations, though in this case the posts were not limited in number. Formerly the colleges at Oxford and Cambridge had each their own separate examinations for scholarships. This method has now been superseded by groups of colleges holding a joint examination, candidates indicating beforehand, in order of preference, the college they would choose if successful. It is probably true to add that Oxford Scholarships are awarded on promise as well as on performance, while Cambridge Scholarships are mainly given on performance, though promise is not entirely excluded from the aftermath. Oxford, like Paris, prizes rather the artistic presentation of facts than their mere reproduction as such; Cambridge attaches more importance to the abundance and accuracy of the facts, their presentation being a secondary matter. The one puts a premium on art; the other on science.

METHODS OF EXAMINATION

Examinations on traditional lines are usually carried out in the case of the most advanced work by a thesis only; in the other grades by means of (1) written papers; (2) oral tests; (3) practical tests; (4) a combination of two or more of these.

Thesis.—A thesis or dissertation is usually required only for the higher degrees of universities; it normally embodies the results of research into some branch of knowledge and is usually looked over by two or more specialists, whilst it is generally necessary to undergo a public examination in addition to the thesis submitted.

Oral Tests.—An oral examination provides the opportunity to test the individual as regards the range of his knowledge, and makes it possible to test many important qualities, such as readiness of wit, presence of mind, common sense, which are not so easily tested by written papers. One useful extension of the oral examination is practised by the headmaster of secondary schools when interviewing candidates who have been qualified by a written examination for admission into a secondary school, to decide whether they are suitable for admission into his school. The interview is also used on a still larger scale by some local authorities who examine orally candidates for senior or technical scholarships. Similarly, candidates who are successful at competitive examinations for entrance into some of the public services, notably the navy, are subjected to an oral examination to determine whether their personality justifies their entry.

Practical Tests.—Oral tests sometimes shade off into practical tests, as in testing foreign languages orally. Such tests are, in fact, designed to test predominantly the manipulative skill of the candidate, whether it be in science, craft-work, medicine or some skilled trade or profession. A doctor or surgeon, for instance, must show that he is familiar with the practical side of his calling, an engineer or plumber must show that he has already attained sufficient skill to be allowed to be certified as capable of following his trade.

Written Tests.—In written examinations the candidates attend for several sessions of one and a half to three hours' duration, and answer printed papers of questions under a prescribed rubric. The number of questions on a paper may vary from a very large number to one or two according to the type of examination. The answers required may consist of a symbol or single word, or a single essay of considerable length, as in the case of a university honours candidate.

Simple Written Examinations.—The simplest form of examination question involves merely a single mental operation and an answer which is right or wrong, *e.g.*, What is twice two? Answer: Four. The children ultimately to be examined are taught an algebraic operation such as: if $a=3$, $b=2$, $c=0$, then $ab=6$, $3c=0$, etc. They work through sets of examples on the operation until they are familiar with it under its various guises. They reach a stage when they can be said to know the operation and are ready for examination. The examiner prepares the examination paper by selecting a large number, say 40, of the simplest form of questions each involving this operation. He tries his question out on a group of children similar in character to those to be examined, and grades his 40 questions in order of difficulty until he is justified in the expectation that only one or two candidates will fail to answer the easiest question and that only one or two candidates will succeed in answering the hardest question. He then sets this examination paper to the group of candidates and is able to produce an order of merit showing the relative ability of these candidates to perform the algebraic operation tested.

A simple examination paper of this character has the merit of objectivity. The questions are simple, can only be correctly answered in one way, are graded in difficulty by an objective preliminary test. The only variable characteristics which affect the result of the examination, apart from the difference in ability to do the algebraic operation, are the temperament and nerves of the candidates. Some pupils are not good examination subjects. Another element of uncertainty is introduced when examiner and teacher are not the same person, for even if the ground is common the teacher may have stressed some points more than others. Again, the moment more difficult questions are introduced into an examination paper a further element of chance is introduced; this is the chance that the form of the question will affect some candidates differently from others; for two questions of equal difficulty but of different forms will be answered with different success by some, at least, of the examinees.

When the subject of examination is English, the element of chance assumes greater importance. Children's knowledge of words and phrases, their ability to understand a short passage of connected prose is conditioned by many other influences than school. Hence children are very liable to suffer even in the simplest form of examination in English by the fact that they do not "know" a word or phrase, not having met beforehand with it, in the question paper. The examiner, even by the most exhaustive preliminary trials, cannot provide against such a possibility and the element of chance affects the scores made by some candidates.

Complex Examination Papers.—Examination papers increase in complexity whenever two or more mental operations are tested. In arithmetic a paper of 20 questions might test 20 processes; or ten questions in an English paper might test facility in the use and comprehension of language in ten different ways. In history, geography, science, etc., where the examiner is required to set a paper covering a prescribed syllabus, the test samples the candidates' acquaintance with the facts specified in the syllabus, and the first test of the quality of the examination paper refers to the goodness of his sampling. In such papers the element of

chance tends to be concentrated upon the average candidate; the very best and the very worst candidates are definitely determined, for they are familiar or unfamiliar with the material put before them in the paper of questions, but the candidates of a little more than average ability may score below the average by a chance unfamiliarity with one question. In much the same fashion the candidates may be concentrated towards the average by the fact that they will have covered the different portions of a syllabus with different degrees of industry, and the chance that the examiner has emphasized different aspects of the subject in a different way from some of the candidates, tends to mass the candidates together in a large group where the scores are about half the maximum. The concentration of the incidence of luck upon the average candidates is one of the reasons why it is inexpedient to pay too much attention to the candidates who score 50%; in the neighbourhood of "half marks" there is a very high probability that a difference of five or six marks between the scores of candidates represents the luck of the examination and nothing else.

The Use of Intelligence Tests in Examinations.—It would be impossible for methods of examination to remain unaffected by the recent development of mental tests. It was not long before mental tests themselves extended their boundaries beyond their native realm of intelligence, and invaded the province of school studies. The technique which had served to test general intelligence was carried over to the testing of academic attainments. This procedure gave rise to standardized scholastic tests. Just as intelligence tests were made to form a scale of mental ages, so were scholastic tests made to form a scale of educational ages. When the scholastic tests were not standardized, when they were not intended to be used over and over again like an electric torch, but were intended to be used once only, like a lucifer match, then they became known (in the United States) as "new type tests."

Ignoring, therefore, the distinction in purpose and in content between these three classes of new tests, and regarding them purely from the point of view of method, we find that a new style of examination has come into being, a style which stands in marked contrast with the old traditional type. And in connection therewith a large body of doctrine has been developed, and a large variety of statistical methods devised, all bearing upon the validity of tests. Prof. F. Y. Edgeworth, writing in 1890, long before the new methods were heard of, gives the following as a fundamental postulate: "The true or standard mark of any piece of work is the average of the marks given by a large number of competent examiners equally proficient in the subject and instructed as to the character and purpose of the examination." This postulate, of vital importance to the old examiner, is of no use at all to the new. For it assumes that judgments vary, and the new examiner regards judgments that vary as invalid. The marking, in fact, should be objective, in the sense that different examiners would inevitably give the same mark to the same examination product. This is possible only when the contents examined on have been so analysed that each question contains only one element, the answer to which must be either definitely right or definitely wrong. It thus carries one mark or no mark at all. Thus the essential difference between the old examination and the new lies in the analysis of the subject-matter into markable elements. The new examiner analyses before the examination, the old examiner after the examination. The new examiner's analysis is complete and definite: it admits of no variation or extension on the part of the marker. The old examiner has a complex product, such as an essay, to mark, and either does not analyse it at all and judges by general impression, or analyses it into such vague factors as style, ideas, logical arrangement and so forth. It thus happens that the main superficial difference between the old examination and the new is that the former requires a small number of long answers, and the latter a large number of short answers.

The new examiner lays great stress on "reliability"—a technical term which means the degree to which the order of merit secured by one application of a series of tests agrees with the order secured by a second application of the same series. The agreement is measured by the mathematical method of correlation. Tests which give a low coefficient of reliability are discredited and rejected. The new examiner, therefore, tests his tests before applying them. He "tries them out" on children who are not genuine examinees.

A subsidiary characteristic of the new testing is that it occasionally probes a lower stratum of knowledge than is reached by the ordinary examination question. It does this through the "limited option" test. Here is an example: "The author of *The Scarlet Letter* is [Hawthorne, Poe, Stevenson, Kipling]." The testee has to underline the right author. He need not recall the author's name, he need only recognize it; and recognition is much easier than definite recall.

The new school tries to keep steadily in view the purpose for which an examination is designed, and modifies the questions according as the purpose is diagnostic, prognostic, selective or evaluative. It is maintained that though an examination may serve more than one purpose, it can only serve one purpose well.

How far has the new examination influenced the old? In England, slightly; in America, profoundly. In the United States the new type of tests has in certain instances superseded the traditional examination. European countries have shown a much more critical attitude towards them. On one side of the Atlantic the new testing is almost universal; on the other side it is sporadic and experimental. The rivalry between the two systems lies not so much in practice as in principles. What the ultimate issue of the contest will be no man can at present tell: much experiment and research must yet take place before a final adjustment is reached. In the meantime it seems fairly clear that each system has its points of weakness and its points of strength. The main merit of the new system is that it succeeds as far as seems possible in eliminating the element of chance; its main defect is that it fails to test—directly at any rate—constructive and creative ability. This is a grave defect, a defect from which the traditional examination is singularly free. But the freedom is secured at the expense of objectivity: the examination result is more liable to suffer from the vagaries of personal judgment.

Since the merits of one system are the defects of the other, it seems reasonable to regard the two as complementary. It is not improbable that both will, in the course of time, be brought within one scheme, yielding a final estimate of ability which would be of higher value than either of the constituent estimates. However that may be, the scientific precision of the new system cannot be ignored. It is a significant fact that no thesis embodying the results of psychological or educational research would be accepted by any university unless those results had been measured by the new methods. (*See* also below, under *United States.*)

Mental tests for examination purposes are actually used by 21 local authorities. An enquiry by the Psychological Society shows that three-quarters of those who answered the questionnaire were making use of them mainly as providing an additional criterion to the orthodox tests, or in adjudicating on borderline cases. They were also found of special value in reducing the disabilities of pupils from small rural schools.

THE TREND OF MODERN EXAMINATIONS IN SCHOOLS

The more old-fashioned examinations were predominantly an audit of fact. Certain specific facts, data or formulae had to be mastered, and the pupil was examined on these. But for many years we have been moving in the direction of testing capacity as well as mere knowledge, and not merely capacity for dealing with specific subjects, say English or arithmetic, but also general ability as such. Here, no doubt, the more advanced of our examiners, especially those dealing with younger children, have been influenced by the modern psychological theory that each individual possesses a certain degree of general ability, and that this is capable of being measured and tested.

At the same time, the unsuitability of numerous examinations for pupils under 16 has been recognized, so that to-day out of the multiplicity of examinations with which the schools were formerly burdened, there are now only three definite types of

school examinations recognized by public authorities in England, each of which possesses a clear aim and perspective: (1) A competitive admission examination for children of 11, success in which procures admission, sometimes with pecuniary privileges, to secondary or central schools. (2) A general school examination for children of 16 or 17, success in which indicates that the pupil has profited reasonably well by a course of four or five years in a recognized school, or, in the case of having attained a higher prescribed standard, has qualified for entrance into the university (matriculation). (3) A higher school examination in a fewer number of subjects, combined in courses open to pupils who have passed matriculation, and taken normally two years after the latter.

The competitive admission examinations are conducted by the local education authorities, each for the children in its area, for admission into its own higher schools, whether as "scholars" or "free-placers." The school examinations are conducted by a university authority, and have no territorial limitation. By a historical accident since the general school examination has grown from the matriculation examinations of the several universities, the first, or general school examination is complicated by the specific requirements for university entrance and is not entirely a general examination.

Competitive Admission Examinations.—The competitive admission examination aims at filling a small number of school-places from a large group of children of a definite age. It usually comprises papers in English and arithmetic treated quite generally. The fact that success is limited to the best few of the competitors means that the element of chance affects but slightly the composition of the final list of successful candidates.

General School Examination.—The general school examination suffers from limitations due to its university origin. Rightly enough the matriculation examination prescribed papers and a syllabus which the particular university considered would secure students prepared to profit by the courses which the university provided. With the increase in the number and scope of university facilities the matriculation examination was widened and made more general. At the same time the "local" examinations of Oxford and Cambridge, and the similar examinations of London, provided tests of a more general character suited in some fashion to the work done in the secondary schools and suited further to furnishing candidates (who fulfilled certain more rigorous regulations) with a qualification that could be accepted for matriculation. The schools were not compelled to submit candidates for any of these examinations. In combination the whole was an "omnibus" attempt at providing matriculation certificates and school-leaving certificates. Subsequently, it became obligatory for the schools to present for the general school examination, which was developed from the "locals," the whole of the members of a form, in order that the general school certificate might be a school-leaving certificate, and the general school examination became an integral part of the education system of the country. It was laid down that the certificate examination should be such that an average scholar who had steadily pursued the regulation course in an approved secondary school should pass. This probably meant that half the candidates should obtain certificates. Obviously, the percentage who should pass should be fixed by the central controlling authority, yet it is doubtful whether 50% is not much too low a proportion. Either the schools are not satisfactory when only half their pupils can be certified as satisfactory products, or the certificate examination is too severe a test.

The general school examination purports to be a general test of average pupils of an average secondary school. Stress is laid naturally upon English and arithmetic as the two general subjects of examination. In addition to these two subjects others are prescribed and by a slow process of release from the university traditions the examination is being widened so that subjects which are taught in an approved school may count equally with each other in the examination. Freedom is being gradually achieved. The domination of Latin, the presumed absolute necessity of mathematics, the limitation of science to physics and chemistry, have gradually been abrogated and the claims of girls to different treatment from boys are receiving recognition. There is a notable movement, made especially in the interests of girls, to secure the recognition of the arts and crafts as adequate alternatives to the more definitely academic subjects of examination. From the earlier position when the examination controlled the teaching in the schools, gradual progress is being made towards the ideal that the examination shall mirror the school curricula, though we are still far from the ideal that each school should be examined on its own curriculum. The examination papers have changed; the number of examination subjects have been notably increased and the character of the papers has been altered. Formerly the paper in any subject aimed at discovering whether candidates were fitted to pursue their studies further in that subject; now the paper rather aims at finding evidence that the candidate has reasonably profited by an approved course of study in school of that subject, and advocates are not lacking of the opinion that the "pass-mark" in each subject should be such that 70% or, even 80%, of the candidates should pass. It is held to be a fault of a school-leaving examination system that out of 100 children who have been reasonably assiduous in their study of a subject, not more than 50 to 55 can pass the examination therein. Little by little the general school examination is becoming really general and the examination papers are gradually approximating to general tests of ability in specific media of thought. No longer does the examination paper test for a minimum quantum of information; it now attempts to discover general ability to think and act within the realms of knowledge of a small number of subjects in which the candidates have acquired reasonable facility in school.

Coincident with, and contributing to this development, considerable improvement has taken place in the technique of examining. Syllabuses have become less detailed and freedom has been given the schools to submit their own syllabuses for approval and subsequent examination. The examination papers themselves are now regarded as the most potent factor in the system, and the composition of the paper, the character of question used, the balance of the whole paper in relation to the average teaching in an average school, each receive careful attention. Boards of moderators revise and approve the papers suggested by one or two examiners. But it is still doubtful whether, in spite of material difficulties, more scope should be given to testing the pupils orally, and whether the teachers should not be directly represented on the body of examiners.

The Higher School Examination.—This examination marks the final stage in specialization at school. It has been greatly improved from its original form, but further elasticity is needed. Some people think it should take the place of the matriculation and serve as entrance to the university, thus liberating the school-leaving certificate from any connection with that examination. This would, however, involve grave difficulties. The whole nature of the examination would probably have to be modified and consideration would still have to be taken of the fact that for many candidates who are not going to the university, it serves first and foremost as a final test of their school studies. It is worth noting that State scholarships are awarded on the results of this examination; they are, therefore, indirectly of the nature of a competitive examination.

Much of the improvement in the technique of examining is due to the work of the secondary school examinations council. In the traditional English manner, inspectors of the Board of Education conduct enquiries into the way in which school examinations are conducted, and pass on from one team of examiners to another, and from one authority to another, the best methods of examining which they discover. Almost equally potent for good has been the action of the Civil Service Commissioners in adjusting their tests to favour modern methods of teaching. There is no definite attempt to train examiners who drift into examining by accident, learn their methods by experience, and only rarely pay any attention to the principles which are at the basis of all sound testing; consequently, there is room for yet further improvement.

The Public Schools Common Examination.—It is worth

noting here that entrance to the public schools (*q.v.*) from the preparatory schools (*q.v.*) is obtained by passing the so-called common entrance, which has replaced the separate entrance examinations formerly held by each individual school. It has lately come in for a severe criticism. It is alleged to lead to an undue study of Latin in young boys to the detriment of subjects like history, geography and the mother tongue while the papers in these latter subjects directly encourage the mere acquisition of a jejune and desiccated information, being in fact rather an audit of memory work than a test of capacity. Further, owing to the limited number of places available in the schools, the examination is tending to become really competitive and so necessitates cramming. Various substitutes have been proposed—recommendations by the preparatory heads, interviews, increase of public schools, or of schools directly attached to them, the last of which, apart from possible evils of inbreeding, seems possible. Mention may also be made here of the examinations of all Colleges of Preceptors taken by the private schools (*q.v.*).

EXAMINATION SCORES

The main aim of an examination is to place a set of candidates in a relative order of merit. It has a prescribed range, between a zero which marks ability below the minimum which the examination is designed to test, and a maximum which marks an ability greater than the examination papers can legitimately assess. Between these limits the examiner used to award marks, now he scores points. The precise system of scoring should be suitable to the purpose of the examination; a system of symbols $\alpha+$, α, $\alpha-$; $\beta+$, β, $\beta-$, etc., serves for some examinations, notably at Oxford, but it is usual to score by numbers with 0 as the zero limit and 100 as the maximum. It is desirable when an examination is repeated annually that the pass-level shall be constant throughout the series. When the numbers of candidates are small on each occasion, the constancy of the pass-level must be maintained by the examiner and it is usual to fix 40% or 50% as the pass-level, and to leave the examiner the task of ensuring that the pass-level for successive years represents the same level of ability. This is an onerous task and calls for a measure of ripe experience and sound judgment, coupled with a somewhat rare ability in setting suitable examination papers. When the candidates at each examination run into thousands, a more objective method may be substituted for the subjective judgment of the examiner. The pass-level may be fixed at such a point on the scale that X% always pass. X may be fixed at 50 or 60, or even 85, to suit the purposes of the examination.

Scores are arranged so that candidates are spread between 0 and 100 in such a fashion that if x candidates score a% then x candidates, an equal number, also score $(100-a)$% and that about 40% of the candidates score between 41% and 59%. A curve of distribution of the candidates then resembles the lines of a broad-brimmed cocked hat. Such a distribution happens readily in arithmetic, but to ensure it in English and kindred subjects needs more careful examining. The form in which the spread of the marks finally falls depends upon the examination paper and the schedule of marks prepared by the examiner, and is, therefore, largely within his control.

When an examination includes many papers, it is usual to record passes on the single papers with some form of allowance for candidates who do exceptionally well on one or more papers and just miss passing on others. This requires that the several examiners shall so arrange that their pass-marks measure similar degrees of ability. Subjectively, this is difficult, objectively (should time allow) this equality between different papers may be determined by the regulation that the pass-mark per paper shall be that mark which will secure that Y% of the candidates who took the paper shall pass.

In competitive examinations, where there are several papers, the scores are usually added together, with or without allowances for exceptional ability displayed on one or more papers. In certain cases candidates have to score a certain number of marks, so to say, "below the line," as in some civil service examinations, before they are credited with any marks at all. When the papers are marked by α, β, etc., final positions are determined either by the number of αs or by the general impressions of the candidates' work.

Borderline Cases.—In close relation to the treatment of examination scores lies the necessary consideration of those candidates who nearly or only just succeed; these candidates are frequently designated as borderline candidates. In most examinations borderline candidates receive special attention, careful consideration being given to their work as a whole and systematic allowances made on principles prescribed by previous experience. The method of scoring differences facilitates the consideration of borderline cases.

Closely allied with the consideration of borderline cases is the necessity in competitive admission examinations of young pupils (say boys and girls of 11 +) of giving them an age allowance. Usually the age allowance is determined by rule of thumb methods which secure that the numbers of successes shall be evenly distributed in each month of the age group.

Finally, in such examinations some definite allowance is made for the teacher's judgment on the relative merits of the candidates whom he submits. In these and other specially appropriate ways, means are taken to secure fair treatment to all candidates.

The Organization and Conduct of Examinations.—The organization of examinations so that each candidate shall be treated in precisely the same way as every other candidate, increases in complexity with the number of candidates examined. The greatest precautions are taken to ensure the secrecy of the examination papers before and during the examination, and to isolate the individual candidates in the examination room. Both the seating arrangements and the supervision should be adequate to remove all temptation of copying. The hygienic conditions and the time of year and day should be such as to reduce the strain to a minimum. The examination time-table should tend to minimize the effects of mental fatigue.

Marking the Scripts.—The chief examiner usually sets the papers of questions and marks some of the scripts; the assistant examiners mark scripts. The preliminary stages in marking are usually occupied with the determination of a schedule of marks. All markers read a sample batch of scripts and then meet to discuss what the particular batch of candidates have done with the particular paper. The chief examiner has provided a provisional schedule of marking, and this schedule is modified in the light of the experience gained from reading the samples of scripts. The marking thus tends to be objective and to become merely a grading of the candidates against each other. The markers in conference determine upon a revised schedule of marks which is strictly followed thereafter; they disperse and, later, supply the chief examiner with samples of their marking. Markers, being human and being required to work under pressure against a time limit, inevitably err; many of their vagaries occur in mechanical matters such as totalling marks. The marking of simple questions is merely a matter of eyesight. When the questions are more complex, or are of the kind which require essay-type answers, marking becomes more difficult; human judgment in these cases does not always act consistently, and inconsistencies of marking are inevitable. It is a function of the chief examiner to standardize the work of several examiners engaged on the same paper.

The Pass-mark.—In competitive examinations there is no pass-mark, the number of awards is predetermined. In university and professional qualifying examinations, where marking is by figures and not impressions, a pass-mark is fixed to separate those who pass from those who fail. In some cases the pass-mark is 50% of the maximum, in others it may be 30% or 70%. Reference has already been made to the unavoidable incidence of chance in the relationship between the candidates and the questions. There is also an inevitable incidence of chance in the relationship between the candidates and the markers. In both these cases the incidence of chance tends to be concentrated upon the candidates of average ability, so that of any set of candidates the markers may decide on the relative merits of the best fourth and of the worst fourth with comparative certainty, but their decisions concerning the middle half are much affected by luck.

Consequently, the pass-mark should always occur in such a position as to leave the middle half definitely as "passes" or "failures"; this means that the examination papers should be either so difficult, or so easy, that the "pass-mark" falls on the slope of the cocked-hat curve which shows the spread of the marks. If the curve is a symmetrical cocked hat, the pass-mark should not be 50%, but less than 40% or more than 60%. If the pass-mark is 50%, then the curve should be a "skewed" cocked hat. In other words the relation between the difficulty of the examination papers and the pass-mark should be such that the borderline candidates are few in number.

The fixation of the pass-mark is the business of the examining authority. It is urged that the pass-mark for a practical examination should be higher since candidates either can or cannot perform the manipulative operations tested. Such a contention implies that the test is a first-class sample of all the manipulative operations which might be tested. In the examination for teachers' certificates the pass-mark is very low, for most of the candidates have been specially selected and specially trained and, on these counts, are theoretically qualified for a certificate, and the examination result is merely a confirmation of the goodness of the previous selection and the training. It may reasonably be urged that the general school examination should be conducted similarly. Secondary scholars tend to be specially selected; they are specially trained or taught in approved schools by registered teachers on an approved curriculum, so that the examination should be so arranged and the pass-mark should be so low that a large majority of these scholars should pass the examination at the conclusion of their course. So liberal a view of the situation runs counter to the university tradition so definitely that it is only by slow degrees that the general school examination system is being reformed. It is, of course, handicapped, as we have seen, by the two somewhat incompatible examinations, matriculation and leaving-school certificate being linked together, yet to divide them is difficult on the score of expense and of duplication of examinations, which is bad alike for pupil and teacher.

Checking the Scores.—A system of checking the scores is inevitable. Mechanical inaccuracies are readily discovered; inconsistent marking may be detected. A staff of experienced checkers is required and their efforts must be concentrated upon the scripts of candidates on or near the borderline.

PROS AND CONS OF EXAMINATIONS

Against examinations, mainly of the orthodox or traditional type, the following are some of the objections formulated. Most of them apply both to competitive and pass examinations. In the case of the former they are certainly more difficult to answer, but till we have found some other means of selection than competition, most of the defects inherent in such examinations must exist, though some are partially neutralized by the addition of an interview.

(1) They destroy natural interests and concentrate the pupil's attention on the subjects of the examination to the exclusion of all others. They need not necessarily do this in the case of pass examinations at least, if the papers are carefully graded and pupils take them in their stride. (2) They are apt to furnish the pupils too exclusively with ready-made opinions. This is a large subject and raises the whole question of the rival claims of originality and tradition in education. (3) There is an inevitable tendency for examinations to increase in difficulty. If the ordinary moderators cannot prevent this, the tendency could be checked by a periodical overhaul of the examination. (4) The questions are frequently unfair. The presence of actual teachers on the Board of Examiners would minimize this and also the previous objections (1), (2) and (3). (5) Difficulty of maintaining a standard of assessment between different examiners. This danger has been and is increasingly successfully dealt with. (6) There is too much stress laid on written work, insufficient or insignificant importance attached to the oral test. This could be met by extending the oral test or interview to all cases that mattered, such as borderland cases. (7) The practice of making a candidate who has failed in one subject take the whole examination over again has little logical justification. This anomaly has been rectified in some cases, but the whole matter needs serious reconsideration. In France, for instance, in the *licence* the system of taking the examination piecemeal (*see* above) is now the rule. (8) Examinations impose too great a strain on growing pupils, especially girls. This can be largely met by readjustment of the examination on lines suggested in (1), etc. (9) Public examinations are unnecessary. Teachers are sufficiently capable of examining and assessing their own children. The co-operation of the teacher is most desirable, but certificates, to have public validity, need a public guarantee.

On the other hand, a large number of people believe, rightly or wrongly, in the stimulus provided by an examination at the close of, or at least at a definite stage in, the pupil's career. They are strongly convinced of the value of such an examination in inducing the pupils to round off and codify their stock of knowledge, and in enabling them to mobilize and use it at short notice. Again, when the oral test or interview is employed, a more or less "all round" view of the pupil is possible. Paper work deals rather with actual performance, an oral test or interview especially helps to discover promise.

Moreover, no one seriously contests the necessity of examinations for professional people, however much the examination may be capable of improvement. Criticism mainly centres round school examinations, yet the average business man, while desirous of having a headmaster's recommendation, is also anxious to have an independent estimate of the pupil's ability from another authority. Moreover, the State, the local authority and the parents also have their rights in the matter. Full justice will be done to the teacher, if, as has been suggested, he is given a position on the board of examiners.

Examinations, whether pass or competitive, cannot in the public interest be abolished till something has been found to take their place. They act as the machinery for sifting out the different kinds and degrees of capacity of the nation. In fact, it is in the further improvement of the machinery, much as it has been improved in the past, that the principal hope lies, whether it be an extended use of intelligence tests for young children, a preliminary selection for various callings by psychological tests, or a greater flexibility in the examinations for older pupils, leading possibly in the long run to some half-way house towards the American method of "accrediting" in the way of giving credit for certain subjects to the pupil on his certificate, and taking the word of the duly recognized school that adequate time has been devoted to them, while in the sphere of the universities, a degree may be obtainable by a less rigid course of study either in the way of a larger choice of subjects, or combinations of them, than at present is allowed in most British universities.

EXAMINATIONS IN UNITED STATES

Examinations in the schools and universities of the United States have developed in much the same way as in European educational systems. They have not been as numerous as in Britain, and there are fewer examinations conducted by outside or extramural examiners. Very early many universities began to admit students without examination, provided that they had graduated from an accredited high school, and this is now the common policy of most State universities. Many universities, however, still insist upon examinations. In addition to examinations conducted by the

schools themselves, there are those given by many special examining boards, such as State, city and county boards of examiners for certifying teachers, the College Entrance board and Civil Service commissions.

The three methods of examination have usually been the written examination, the oral examination and more rarely the practical test. The last two are not very common, and the oral examination usually consists of random questions put by the examiners, who then register a total impression of the candidate. The written examination, therefore, is the most important method. Until recently this has consisted of written answers in the essay form to more or less general questions set by the examiner. The value attached to each question is subjectively determined by the examiner, and his scoring of the answers is based upon the general opinion of their worth. This subjectivity of the usual examination has been severely criticized by many educators. The same paper scored by many teachers will receive marks scattered all the way from very low to very high. The same examiner will mark differently at different times.

During the period of criticism of the old-type examination, the standard educational test and the intelligence test were being developed. In this connection there grew up a technique of constructing questions, evaluating them and standardizing the total test. The construction of an examination in a school subject for nation-wide use (generally called a standardized educational test) is now quite a technical matter. The effect of this was immediately felt in the ordinary examination and there is now the so-called new-type or objective examination, which calls for a specific response to an item, this response being made by underlining, checking or writing a word or at most a phrase. In an old-type examination the candidate might, for example, be asked to write an essay in answer to the question, "Describe the secretion of gastric juice." In the new-type examination (examples taken from D. G. Paterson, *Preparation and Use of New-Type Examinations*, Yonkers 1925) his knowledge about gastric juice would be tested by his response to short items, sometimes containing both true and false information, sometimes incomplete. Such statements may take several forms, as will be illustrated by examples from different subjects:

Analogy: Gastric juice is to the stomach as (saliva, adrenin, *tears*, bile) is to the lachrymal glands.

Completion: The part of a circle included between two—and an—is called a sector.

Recognition: Planets move around the sun in orbits that are circular, *elliptical*, hyperbolic, cylindrical.

True-False: The chief crop in Ohio is tobacco.

There are many different varieties and combinations of such forms, and those quoted above must be considered only as samples. These new-type examinations are now being widely used in all types of schools.

B. D. Wood describes such examinations at the university level and C. Russell shows in detail how school-teachers can construct such examinations in all subjects in the elementary school. He goes further and suggests how they may be used as effective teaching devices. None of these authorities advises the absolute abandonment of the old-type essay examination, but all of them believe it to be insufficient for the accurate examination of the pupil. All of them emphasize the necessity for a careful construction of the new-type examination, and they maintain that it can be made to measure the pupil's ability to reason. They deny that it merely tests the memory of the pupil.

These new-type examinations are now being used by such examining bodies as the College Entrance Examination board and the board of examiners of the New York city board of education, and by many civil service commissions, both State and municipal. In *Public Personnel Studies*, a journal issued by the Bureau of Public Personnel Administration, Institute for Government Research at Washington, suggested examinations for a great many civil service positions have been published. Almost all of these examinations are of the new type.

(R. Pi.)

EXARCH, a title that has been conferred at different periods on certain chief officers or governors, both in secular and ecclesiastical matters. Of these, the most important were the exarchs of Ravenna (*q.v.*). In the ecclesiastical organization the exarch of a *diocese* (the word being here used of the political division) was in the 4th and 5th centuries the same as primate. This dignity was intermediate between the patriarchal and the metropolitan, the name patriarch being restricted after A.D. 451 to the chief bishops of the most important cities (*see* PATRIARCH). The title of Exarch was also formerly given in the Eastern Church to a general or superior over several monasteries, and to certain ecclesiastics deputed by the patriarch of Constantinople to collect the tribute payable by the Church to the Turkish government. In the modern Greek Church an exarch is a deputy, or legate *a latere*, of the patriarch, whose office it is to visit the clergy and churches in the provinces allotted to him.

EXCAMBION, in Scots law, the exchange (q.v.) of one heritable subject for another [from Lat. *cambire*, possibly from Gr. *κάμπτειν*, to bend]. The modern Scottish excambion may consist in the exchange of any heritable subjects whatever, *e.g.* a patronage or, what often occurs, a portion of a glebe for servitude. Writing is not, by the law of Scotland, essential to an excambion. Power to excamb was applied to an entailed estate by the Rutherford Act of 1848, and the necessary consents of heirs were regulated by the Entail (Scotland) act of 1882.

EXCAVATION. In civil engineering such as dock, harbour, canal, rail and road operations, the excavation of all manner of soil and the frequent construction of dams with the spoil, is of great importance. It is a special branch of engineering, and has been developed rapidly since the construction of the Manchester and Panama ship canals, in both of which the steam power shovel was extensively used. Even in the erection of big buildings, excavations have to be made for the foundations and basements; and though this task is not comparable in magnitude with some of the others, it may be of interest to quote the result of investigations made by the United States bureau of public roads, which gives the average cost of unskilled labour for excavating one cu.yd. of soil as $0·586, and that for rock as $1·61, when the average rate of pay was 23·9 cents per hour. It is further asserted

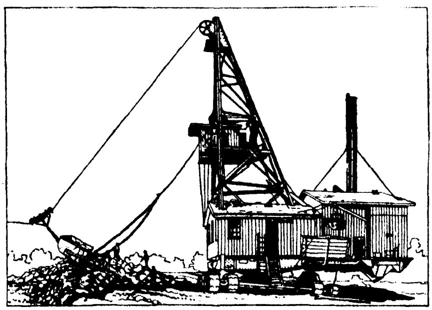

FIG. 1.—6-YARD DRAG BUCKET OPERATED FROM TOWER AT WORK ENLARGING A LEVEE IN THE LOWER YAZOO DISTRICT, MISSISSIPPI

by competent authorities that the cost of excavation for buildings ranges from 30 to 40% of the total cost of the foundation work.

The Crane Navvy, or Power Shovel.—This is principally employed in open-face mining and quarrying, in stripping overburden, in excavating clay and chalk, and also for general contracting work. A view of the machine with the dipper and arm in relation to the jib, is shown in Fig. 1. The bucket or dipper makes an upward cut and is therefore suitable for working against relatively steep faces. The contents are discharged from a hinged door at the back of the bucket, and the depth of cut is regulated by racking the bucket arm in and out at the point where it engages with the jib arm or boom. Electrically-operated machines hav-

The dragline and crane navvy may, in certain sizes, be converted from one type to the other. Fig. 3. Skimmer scoop. Fig. 4. Skimmer scoop used as trenching machine

ing a dipper capacity of 10 to 12 cu.yd. are in operation in the brown coal fields at Victoria, Australia, and similar machines are at work in tin mines in Nigeria. The largest power shovel has a dipper capacity of 15 cu.yd., and it is fitted on crawler tracks or caterpillar wheels. The skimmer scoops (figs. 3 and 4) are special purpose machines, somewhat on the lines of the crane navvy. They have a low-lying horizontal boom upon which the cutting scoop runs, and are suitable for removing shallow overburden, ripping up the surface of roads, and similar work where a shallow horizontal cut is desired.

The Drag-line Excavator.—This machine is most generally adopted to-day as a general purpose excavator. It is capable of digging to a considerable depth beneath its own level, and, as the digging stresses are taken by ropes, its jib can be made lighter and longer than that of the crane navvy; also it can be set at the most convenient angle for working. When the excavator is in operation one rope raises and lowers the bucket to and from the digging position, while the second rope drags the bucket over the ground, filling it during the process. By manipulating the two ropes in correct relation to each other, the filled bucket can be raised, lowered, or brought into a vertical position at the point where the soil is to be discharged. By revolving the machine on its wheel base the required dumping point can be reached; this may be a retaining bank, a train of vehicles, or a previously made cutting. As a general purpose excavator, the drag-line (fig. 2) stands in a class by itself. It is used for the excavation of docks, railway cuttings, canals, ditches; of sand and gravel from dry and flooded pits; and also for foundation and general excavation work. Drag-lines require a level path, and cannot dig such hard material as the shovel. This machine was invented in America and is manufactured by many builders there.

The drag-line excavator and crane navvy are closely related to one another, and, in all ranges of size, are capable of being converted from one type to another. They take the general form shown in the illustrations (figs. 1 and 2). The engines, gear, winches and control levers are contained in a cabin; the jib is hinged on the revolving frame. The machine is capable of being revolved upon its tracks by means of the roller-ring base shown. Such excavators travel mostly under their own power, and the adoption of caterpillar wheels enables them to negotiate difficult paths; sometimes they are mounted on rail tracks. Steam engines, internal combustion engines, or electric motors, are adopted as power units. The Diesel engine and Diesel-driven electric sets have also given good results on the larger sizes. Quite a variety of special-purpose machines, combining the elements of the above, have been developed (figs. 3 and 4), *e.g.*, the *slack line cableway* excavator, digging over big distances within a defined area, and an amphibious type of the *barge* or *ladder* dredger. The crane-and-grab combination is also used on medium soils.

Slack Line Cableway Excavator.—A typical plant consists of a rope track set at an incline. One terminal of this track is a movable anchorage near ground level, and the other is a relatively tall mast or tower suitably guyed and strengthened. The height of this tower is governed by the length of span, which may be from 800 to 1,000 feet. The digging bucket runs to and fro along the track, travelling in one direction by gravity, and being hauled back by a second rope which transmits the power for both digging and conveying. The bucket is lowered to digging position by slackening the track line, thus enabling the hauling rope to draw the bucket into the ground. With the bucket filled and the

TYPES OF AMERICAN EXCAVATORS AT WORK

1. **Gasoline shovel used for heavy work, shown removing old pavement on city streets, where traffic delay must be avoided. In this type speed and economy are essential factors**
2. **Large buckshoe excavator operating between gas and water mains in a city street. Perfect control of machine ensures safety to pipe lines**
3. **Air shovel or pneumatic excavator working in tunnel for new subway, New York city. Pipe line at lower left brings high pressure air supply from compressor at surface. Girders overhead support temporary roadway**
4. **Gasoline shovel used for logging a road in the State of Washington. The machine rests on the log roadway**
5. **Large clamshell excavator handling rock near Tulsa, Oklahoma. The halves of scoop dig into loosened rock, closing by power device (top)**
6. **Steam shovel used in excavating building sites. Caterpillar treads allow the machine to move readily to any part of the area to be excavated**
7. **Gasoline shovel for housing or city development work. Where any large area is to be excavated, railway is generally used for removing earth, stones, etc.**
8. **Railroad type steam shovel mounted on continuous treads. The machine has a $3\frac{1}{2}$ yd. dipper; two scoopfuls fill a car. This type of machine was used in building the Panama Canal**

EXCAVATING MACHINES OF ENGLISH MANUFACTURE IN OPERATION

1. View of petrol (gasoline) excavator with special arm, working as back trencher, to dig a deep, narrow line for housing drains. 2. Petrol (gasoline) machine (*see* fig. 1), for the excavation of old road surfaces under repair. A special arm is used in this work, consisting of a channel beam along which scoop is moved. 3. Caterpillar shovel (*see* figs. 1 and 2), fitted with derrick for general excavating. Scoop in this type digs toward the machine. 4. Large oil-electric dragline scoop, used where coal and water are unobtainable. In rear of housing is Diesel oil engine, driving electric generator. Scoop and derrick are operated by current passing through motors in front of housing. 5. Small petrol (gasoline) driven excavator, shovel type, for foundation work. The machine, controlled by one man, turns in a complete circle

track again made taut, the hauling rope conveys the load to the discharge point. All operations are effected by a power-driven winch having two winding drums to which the track and the digging ropes are led after passing over sheaves at the head of the tower terminal. A modification of the slack-line cableway excavator is the *power or drag-scraper,* whose bucket travels backwards and forwards over the surface of the ground, and, when loaded, automatically sets itself free from the digging position. One method of discharge is to provide a ramp, at the home terminal, up which the bucket rides to a tripping engagement, which enables the material to be discharged.

The Bucket or Ladder Dredger.—This, a modification of the well known barge dredger, runs on a rail track, an example of which is shown (fig. 5). Here a series of continuously running steel buckets with cutting edges are employed; these engage with the soil and convey it to the receiving hopper, which is at a height suitable for discharging material into vehicles. The main boom, or bucket-supporting arm, is composed of two parts, and the working angle can be adjusted up to 45° from the horizontal. These dredgers are suitable for removing shallow overburden, cleaning up marginal banks, and also for excavating areas. The *crane-and-grab combination* may either be a self-contained machine—which type is well known—or it can be adapted to work from the jib of a drag line excavator, in which case one winch drum is used for operating the digging and hoisting rope, and the other for operating the rope for opening the grab to release the load after it has been slewed into the delivery position.

AMERICAN TYPES

Revolving Shovels.—These are standardized (1928) and are built in three size buckets—½ to 1½ cu.yd. for small car, truck and wagon loading; 2½ to 4½ cu.yd. (heavily constructed) for quarry work; and 5 to 12 cu.yd. for overcasting overburden in "strip" or surface mining or for very large iron ore and quarry operations. All three sizes are full-revolving and most are mounted on crawling traction. They are capable of digging very hard material and prepare their own path as they dig ahead of themselves and above the surface on which they rest.

Tower Excavators consist of a head and a tail tower, a bucket being loaded and pulled along on the ground toward the head tower by a drag line. Attached to the rear of the bucket is a trolley sliding on a track cable which is raised slightly when filling and dumping the bucket and raised high to allow the bucket to travel back by air to the digging point. They give a greater horizontal displacement of the "spoil" or excavated material than any other machine. (G. F. Z.; G. B. M.)

EXCELLENCY, a title or predicate of honour. The earliest records of its use are associated with the Frank and Lombard kings; *e.g.*, Anastasius Bibliothecarius (d. *c.* 886) in his life of Pope Honorius refers to Charlemagne as "his excellency" (*ejus excellentia*); and during the middle ages it was freely applied to or assumed by emperors, kings and sovereign princes generally, though rather as a rhetorical flourish than as a part of their formal style. Its use is well illustrated in the various charters in the Red Book of the exchequer, where the addresses to the king vary between "your excellency," "your dignity" (*vestra dignitas*), "your sublimity" (*vestra sublimitas*) and the like, according to the taste and inventiveness of the writers. Du Cange also gives examples of the style *excellentia* being applied to the pope and even to a bishop. With the gradual stereotyping of titles of honour that of "excellency" was superseded in the case of sovereigns of the highest rank, about the beginning of the 15th century. Dukes and counts of the empire and the Italian reigning princes continued, however, to be "excellencies" for a while longer. In 1593 the bestowal of the title of *excellence* by Henry IV. of France on the duc de Nevers, his ambassador at Rome, set a precedent that was universally followed from the time of the treaty of Westphalia (1648). This, together with the reservation in 1640 of the title "eminence" (*q.v.*) to the cardinals, led the Italian princes to adopt the style of "highness" (*altezza*) instead of "excellency." In France, from 1654 onwards the title of *excellence* was given to all high officials, and this example was followed in Germany in the 18th century.

The subsequent fate of the title varies greatly in different countries. In the British Empire it is borne by the viceroy of India and all governors of colonies and ambassadors. In the United States it is part of the official style of the governors of States, but not of that of the president; though diplomatic usage varies in this respect, some States (*e.g.*, France) conceding to him the style

of "excellency," others (*e.g.*, Belgium) refusing it. The custom of other republics differs: in France the president is addressed as *excellence* by courtesy; in Switzerland the title is omitted; in the South American republics it is part of the official style (Pradier-Fodéré, *Cours de droit diplom.*, i. 89). In Spain the title of *excelencia* properly belonged to the grandees and to those who had the right to be covered in the royal presence, but it was extended also to high officials, viceroys, ministers, captains-general, lieutenants-general, ambassadors and knights of the Golden Fleece. In Austria the title *Exzellenz* belonged properly to privy councillors. It was, however, extended by custom to all the higher military commands from lieutenant-field-marshal upwards. Ministers, even when not privy councillors, are styled *Exzellenz*. In Germany the title was borne by the imperial chancellor, the principal secretaries of State, ministers and *Oberpräsidenten* in Prussia, by generals from the rank of lieutenant-general upwards, by the chief court officials, and it was also sometimes bestowed as a title of honour in cases where it was not attached to the office held by its recipient. In Russia the title was very common, being borne by all officers from major-general upwards and by all officials above the rank of acting privy councillor. Officers and officials of the highest rank had the title of "high excellency." Finally, in Italy, the title *eccelenza*, which had come to be used in the republics of Venice and Genoa as the usual form of address to nobles, has become as meaningless as the English title "esquire" or the address "sir," the usual form of address to any stranger.

In the diplomatic service the title of excellency is technically reserved to ambassadors, but in addressing envoys also this form is commonly used by courtesy. (W. A. P.)

EXCELSIOR SPRINGS, a city of Clay county, Missouri, U.S.A., 25m. N.E. of Kansas City, at an altitude of 939 feet. It is on Federal highway 69, and is served by the Chicago, Milwaukee, St. Paul and Pacific and the Wabash railways. The population in 1920 was 4,165 (90% native white). There are over 20 medicinal springs, which supply five different kinds of mineral water, and the city is an all-year health resort. It was founded about 1881 and incorporated in 1886. A city-manager form of government has been in operation since 1922.

EXCESS PROFITS DUTY OR TAX, a tax on the excess of the actual profit of an accounting period over a standard of profit.

THE UNITED KINGDOM

Following the outbreak of the World War in 1914 it was apparent, from the movement of the monthly index numbers of the wholesale prices of commodities, that profits of businesses, especially of those concerns whose products would immediately be in increased demand, would move upwards at a rate even greater than that shown by the index number. The results shown by accounts of trading concerns embracing part of the War period more than confirmed this anticipation. So the excess profits duty was born. It was imposed by Part 3 of the Finance (No. 2) Act 1915, which passed into law on Dec. 23 of that year.

The excess profits duty was a duty, where a chargeable profit existed, on the profit of businesses carried on in the United Kingdom or carried on elsewhere by persons ordinarily resident in the United Kingdom. Agriculture, professions and employments were exempt. The duty was imposed upon the profit of a business concern as an entity, and not by reference to the profit or income of individuals as such. A chargeable amount of profit was the excess of the actual profit of an accounting period over a standard of profit increased by certain free allowances. An accounting period was in general the period for which the accounts of the business were made up. Profit was determined, subject to certain modifications, on the principles which determined profits under the Income Tax Acts.

Standard of Profit.—The standard of profit was represented in the normal case of a business which had been carried on for some years prior to the outbreak of war by either: (a) a profits standard, or (b) a percentage standard. A profits standard was normally the average profit of any two of the three years to the end of the last accounting period ended before the outbreak of war. A percentage standard was normally a statutory percentage on the amount of capital employed in the business at the end of the last accounting period ended before the outbreak of war. Provision was made for the increase of percentages in certain cases.

To preserve comparability provision was made for a reduction or increase of the profit of the accounting period, by reference to a statutory percentage upon the additional or reduced amount of capital employed in the accounting period as compared with the capital employed during the period or at the date to which the standard related.

Capital as computed for the purpose of the duty represented the proprietors' trading capital, and borrowed money was, therefore, excluded from the computation of capital. In general, capital of a business consisted of money; assets acquired by purchase at the price paid, subject to any deductions for wear and tear or replacement; debts due to the business and assets not acquired by purchase taken at their value when they became assets of the business. Accumulated profits employed in the business were treated as capital; any capital (the income of which was not taken into account in computing profits for the purposes of duty) and any borrowed money or debts were to be deducted in computing the capital.

Special provisions affording relief from the full weight of the duty were introduced as from Jan. 1, 1917 in the case of small businesses.

A percentage—equal to the percentage rate of duty in force for the period concerned—of any deficiency of profit of a business below the standard in any accounting period was set off against the amount of duty applicable to an excess of profit over the standard in another period. The rate of duties varied between 40% and 80% of the excess profits chargeable.

Munitions Levy.—The Munitions Levy was imposed by the Munitions of War Act 1915. It applied only to certain concerns engaged in the manufacture of munitions which the minister of munitions "controlled" under the provisions of that Act.

The Act limited the profits to a retainable amount, ascertained in accordance with the statute and rules made thereunder. Any excess of net profits of the establishment over such retainable amount was payable to the exchequer as a munitions levy.

Controlled establishments liable to the munitions levy were also liable to the general excess profits duty but their total liability was limited to the higher of the two charges. From Dec. 31, 1916, the rate of excess profits duty became, practically without exception, the heavier charge. The munitions levy was therefore terminated at that date.

Repeal of the Duty and Special Reliefs.—Excess profits duty was abolished by the Finance Act 1921.

Where a taxpayer had been required to pay an amount of duty in excess of his aggregate net excess profits over the whole period for which the duty was in force, provision was made that the excess should be remitted or repaid.

Part of the productivity of the duty was due to the continuous rise of the price level. To take care of any heavy losses arising from a heavy fall in prices, after the duty was repealed, complex provisions were contained in the Finance Act 1921, granting three reliefs in connection with trading stocks, two of which were alternative to one another.

The net amount of duty collected and retained in the British Exchequer from the inception to the end of the tax was approximately £1,280,000. (W. H. C.)

UNITED STATES

Although during the Civil War the State of Georgia had adopted (1863) a tax on business profits in excess of 8% on the capital stock, at rates varying from 5% to 25% according to the amount of such excess profits, the first Federal excess profits tax was adopted in the Act of March 3, 1917, for the purpose of creating a "special preparedness fund." After the United States entered the World War, this tax, at higher rates and in more complex form, was continued in the Acts of Oct. 3, 1917, Feb. 24, 1919, and Nov. 23, 1921. In all these Acts, the American tax was aimed primarily at "supernormal profits," *i.e.*, profits in excess of normal profits, rather than "war profits," *i.e.*, profits in excess of pre-war

profits, which served as the basis of the British excess profits duty. The decision to base the tax chiefly on supernormal profits was made deliberately by the framers of the law on the ground that an exemption based upon invested capital was simpler, better designed to serve as the basis of a permanent tax, and more equitable in that it prevented taxpayers from escaping the tax merely because they had been unusually prosperous before the World War. Under the American tax, a business which had been unusually profitable before the war and merely maintained during the war the former rate of profits, was still subject to a heavy excess-profits tax. However, minor recognition of the war-profits idea was incorporated in the Act of Oct. 3, 1917; and for the one year 1918 a dual or alternative tax was imposed, the taxpayer in effect paying an 80% war profits tax or an excess profits tax at progressive rates of 30% and 65%, whichever tax was larger. During the years 1919–21 only the excess profits tax was retained.

The 1917 tax applied to all trades and businesses, including professions and occupations, but beginning with 1918 the tax was confined to corporations, excluding the so-called "personal-service corporations." The normal exemption or "excess-profits credit" consisted of a specific exemption of $3,000 plus 8% of the invested capital. Income in excess of this credit but not in excess of 20% of the invested capital was taxed (after 1918) at the rate of 20%, and the remaining income, if any, at the rate of 40%. The upper rate for the year 1917 was 60% and for 1918, 65%. Under the Act of Oct. 3, 1917, the specific exemption to individuals and partnerships was $6,000, but only $3,000 to corporations.

Judged by the standard of productivity—the most important quality of a war tax—the excess profits tax was conspicuously successful during the World War. The approximate yield of the tax was as shown below:

Excess Profits Tax Returned for Calendar Year

1917—Individuals, etc.	$ 101,249,781	
Partnerships	103,887,984	
Corporations	1,638,747,740	
Total		$1,843,885,505
1918—Corporations only		2,505,565,939
1919 " "		1,431,805,690
1920 " "		988,726,351
1921 " "		335,131,811

The figures for 1918 represent possibly the largest annual amount ever produced in one country by a single tax. During the years 1917–19 the excess-profits tax produced more than 25% of the total ordinary receipts. But despite the high rates, the tax was collected without crippling industry, owing to the high level of profits and to the protective effect of the normal exemption, the relief provisions, and the large degree of administrative discretion authorized in the law.

In accordance with the promises of both political parties, the tax was repealed, after stubborn opposition, as from Dec. 31, 1921. The termination of the tax gave rise to no special problems such as arose in Great Britain, because under the American tax the liability of the taxpayer for any one year was not dependent in any important way upon his income for other years. The repeal of the tax was due mainly to the sharp decline in its productivity under peace conditions; its discrimination in favour of over-capitalized concerns and against conservatively financed corporations; the general belief that it was passed on, loaded with additions, to the general body of consumers; its capricious inequalities; and its great complexity. The complexity of the tax, which, in the words of one secretary of the Treasury, threatened to cause an administrative breakdown, is illustrated by the fact that the tax liability for the year 1918 of some of the large corporate consolidations had not been finally determined at the close of the year 1927. Upon the repeal of the excess profits tax, the income tax rate applicable to corporations was raised from 10% to 12½%, and since that time the corporation rate has been markedly higher than the standard normal rate applicable to individuals. (In the Revenue Act of 1928, the corporation rate is 12%, while the highest normal rate for individuals is 5%.) There seems to be a general belief in the United States that "the theory of the excess profits tax is sound," but owing to its complexities and administrative difficulties there has been, since its repeal, no noteworthy movement for its reintroduction.

EXCHANGE: *see* Trade, Primitive.

EXCHANGE, FOREIGN. Foreign exchange, as its name implies, relates to the purchase and sale of foreign moneys. The subject includes the interpretation and significance of "rates of exchange," the operation of the foreign exchange market, and, on the more theoretical side, the reasons why a particular currency is bought or sold, and all the factors accounting for its supply and demand. These last form part of the general science of economics, and also react upon the more practical questions of trade, investment and interest rates.

A rate of exchange between two countries is the price of one country's currency expressed in terms of the other's. From this it would seem that there are two alternative ways of expressing the rate, *e.g.*, £1=$4.866, or $1=49¼ pence. By custom, only one of these ways is adopted. Thus, in New York, all rates except sterling are quoted in cents per unit of foreign currency. In London, most rates are quoted in foreign currency per pound sterling, but the Lisbon, Eastern and most South American rates are quoted in pence per unit of foreign currency. To cite a few examples, Paris would be quoted, say, frs. 121, Rome lire 92, but Bombay at 1s.6d. (per rupee) and Brazil at 7d. (per milreis). As regards British Empire rates, Canada is quoted in dollars per pound sterling, and the Australian and New Zealand quotations express the price in London of £100 in Australia or New Zealand. The South African exchange is quoted both ways, *i.e.*, "on London," or money in London; or "on South Africa," *i.e.*, money in South Africa.

The next point to consider is what it means when a rate goes up or down. Confining this analysis to London, a sharp distinction must be made between the "foreign currency" rates and the "penny" rates. In the first instance, a rise in the rate, say from $4.86 to $4.87, or from frs. 120 to frs. 121, means that the price of the foreign currency has cheapened, or that, in the jargon of the market, the rate has moved "in favour of" England and "against" America or France. In the second instance, a rise in the rate, say from 1s.6d. to 1s. 6$\frac{1}{16}$d. for the rupee, obviously means exactly the reverse. The test of a "favourable" or "unfavourable" movement is whether the country's currency has risen or fallen in price.

It will probably be simplest to abandon for the moment further consideration of the technicalities of rates and to consider the immediate causes of their rise or fall. For this purpose, it will be easiest to consider two countries alone, such as England and America, though it must be remembered that in practice the rate between two given countries is affected by developments elsewhere in the world.

Foreign Exchange: Supply and Demand.—A rise in the dollar rate in London means that dollars have become cheaper and pounds dearer, while a fall means the reverse. There can be only one cause of such a rise, namely, that more people wish to buy pounds in exchange for dollars than wish to buy dollars in exchange for pounds; so the next thing to see is who wishes to buy pounds or dollars at all. The answer is clear. The pound alone is legal tender in England, and the dollar alone is legal tender in the United States. Everyone who has goods to buy, money to invest, debts to pay or money to lend in England must buy pounds, and everyone who wishes to do any of these things in the United States must buy dollars. The Liverpool importer of cotton from the United States must buy dollars. The London buyer of "American rails" must buy dollars. The British Government, when paying interest or sinking fund on the war debt, must buy

dollars. The London stock-broker who sells British war loan on behalf of an American client must buy dollars, for he has to pay the proceeds to his client in dollars. The British fire insurance company which has to meet an American claim must buy dollars. Conversely, the American exporter of goods to Japan or the Fiji Islands, who sends them in a British ship, must buy sterling, so as to pay his freight. The American importer of Manchester goods, or even of French lace sold to him by a London merchant, must buy sterling. The American who insures himself with a British company must buy sterling every time he pays his premium. The American tourist in England must buy sterling to pay his hotel bill. The American trader who sends his bills to London for acceptance must buy sterling to pay his commission to the London accepting house. The American buyer of British stocks and shares must buy sterling so as to pay for them. The American railroad company with British shareholders on its register must buy sterling so as to pay their dividends.

These examples can be multiplied indefinitely, but can be summarized more conveniently in the following table:—

Sterling is needed to pay for:	Dollars are needed to pay for:
A. *Trade*	
All goods (British or foreign in origin) shipped from Great Britain to U.S.A.	American goods shipped from U.S.A. to Great Britain.
The American use of British ships.	The British use of American ships, and payments by British captains in U.S. ports.
American premiums to British insurance companies.	American claims on British insurance companies.
American commissions paid to British banks, merchants, etc., for services rendered.	Commissions (if any) due in America, as per contra.
B. *Investment*	
American purchases of British stocks and shares.	British purchases of American stocks and shares.
British sales of American stocks and shares.	American sales of British stocks and shares.
American loans to Great Britain.	British loans (if any) to America.
Repayment of loans made in past by Great Britain to U.S.A.	Repayment of loans made by America to Great Britain.
C. *Interest*	
Interest due on British loans to America.	Interest due on American loans to Great Britain.
Dividends due to British holders of American stocks.	Dividends due to American holders of British stocks.

The next point is to see how these various traders, investors, etc., acquire in practice the sterling or dollars that they need. The basic, though least common, means of making payment is in gold. By English law, one gold sovereign contains 123·274 grains of gold, eleven-twelfths fine; and by American law, one dollar contains 25·8 grains of gold, nine-tenths fine. The Bank of England in London engages to buy all gold offered to it at 77s.9d. per ounce, eleven-twelfths fine, while the Treasury in Washington will also buy gold at the appropriate rate. Also gold is legal tender in both countries. Hence anyone in America owing money in England can pay by tendering the weight of gold corresponding to the sum he owes at the above legal rates.

Gold Points.—This is of importance, as it is by these rules that the "par of exchange," or gold equivalent of the pound and dollar, is established at $4.866=£1. In practice, payments in gold are comparatively rare. For one thing, certain countries prohibit the export of gold, and even in England small shipments are checked by the fact that the Bank of England will not sell gold in less quantities than 400 ounces. Also, payment in gold is a costly business. It has to be properly packed, shipped and insured against loss, and while it is on the ocean it is earning no interest. By the time an English debtor has paid in gold, he must deduct about 2½ cents, representing the cost to him per pound's worth of gold shipped, from the dollar equivalent of $4.866 to £1, and so will only get about $4.841 for his pound. Conversely, the American shipper to England will also have to pay about 2½ cents per pound, so that to the dollar cost to him of $4.866 for his pound's worth of gold he must add about 2½ cents, making the total cost about $4.891. These rates of approximately $4.841 and $4.891 are called the "lower" and "upper gold points." It is not at first easy to see why in one case the cost is deducted, and in the other it is added. The best way to look at it is to remember that the result is always adverse to the shipper. The Englishman wants cheap dollars, but only gets $4.841 for his pound. The American wants cheap pounds, but has to pay $4.891 for each. This also explains why gold shipments are comparatively rare. In the vast majority of cases, the Englishman can buy more than $4.841 with his pound, and the American can buy his pound for less than $4.891. They do this as a rule through the medium of their banker, and so long as the rate of exchange remains between the gold points, they do not ship gold.

Methods of Making Foreign Payments.—Now to return to the table of supply and demand. Goods, as a rule, are bought and paid for with some form of bill of exchange (*q.v.*). The bill is drawn in sterling or dollars by agreement between buyer and seller. Thus, the English buyer of American cotton might be drawn on in sterling, while the American buyer of Manchester goods might be drawn on in dollars. In a large number of cases the buyer might have a credit opened for him by his banker (*see* BILL OF EXCHANGE), and the seller would then draw his bill on the bank. In many other cases payment would be made by a cheque drawn by the buyer on his bank—just as if he were paying for his coals or his joint of meat—and sent direct to the seller. In a few cases the buyer might send actual currency notes, either pounds or dollars. Again, dividends on bearer stock are payable by the medium of coupons. These may be regarded as cheques to bearer drawn on the bank responsible for the service of the stock, and so come under the heading of bills of exchange. In many general cases the remitter of funds will buy, from his own bank, a draft drawn on a bank in the country to which he is remitting, and send this to the man to whom he owes the money.

There is thus in constant circulation a huge mass of paper, bills, drafts, cheques, drawn in various currencies upon various individuals and banks, and it is the function of the foreign exchange market to provide a means for dealing with this mass. Until the present century, this was largely done direct. A large proportion of international trade was financed by bills drawn on London, the buyer, wherever he might be, getting a London house to accept on his behalf (*see* BILL OF EXCHANGE). Again, bills of all currencies and descriptions were either sold in the London market or sent to London for collection, with the result that London finance houses were continually in receipt of bills of all kinds. They, therefore, held the famous bi-weekly market "on change," in the Royal Exchange, and every house which had bills drawn in any currency to buy or sell would attend and get the best prices it could. These prices, of course, became the rates of exchange of the day.

The need for speed, and the development of the telephone, have put an end to dealings "on 'change," and the market now operates in different fashion. The best way to understand it is to revert to the relations between the trader and his bank. One or two examples may conveniently be cited. (For explanation of terms, *see* BILL OF EXCHANGE.)

The Banks' Function.—The first is the simple one of an American selling cotton to an English merchant in Liverpool. The American draws on the Englishman in sterling at sight (D/P), and hands the bill and the documents to his New York bank for collection. The New York bank forwards these to the London bank which acts as its agent, and the London bank presents the bill to the Liverpool buyer, gets his acceptance and payment of the bill, then surrenders the documents. The cash so paid, it credits to the New York bank's account with it, and advises the New York bank, which promptly credits the seller's account with the dollar equivalent of the sterling sum. The important thing to note is that the New York bank's sterling balance in London has been increased.

The second example is that of a London investor receiving a

dollar cheque drawn on a New York bank from a Wall street stock-broker who has sold stock in New York on behalf of his London client. The London investor either hands this cheque to his London bank for collection or else sells it to his London bank outright (save for the contingent liability attaching to his endorsement). Whichever he does, the London bank forwards the cheque to its New York agent for collection, and the New York agent presents it, receives payment and credits the London bank's account with it with the proceeds. It then advises the London bank accordingly. If the London investor sold the cheque to his bank, he would be credited with the sterling equivalent there and then. If he handed it to the bank for collection, he would wait for his money until the London bank had been credited with it in New York. In either case, the London bank's dollar balance in New York has been increased.

In many instances, where a debtor has to meet a claim (including a bill of exchange) expressed or drawn in a foreign currency, he buys a draft for the amount from his bank, drawn on his bank's account with its agent in the country concerned. Thus a London importer could meet a dollar bill drawn on him by a dollar draft drawn by his London bank on its New York agent. When an English traveller returned from New York hands dollar notes into his bank, the bank either keeps them against the needs of other customers who may be going to America, or else posts them to its New York agent for the credit of its dollar account.

One more difficult example may be cited. A German buys cotton from America, the terms of the deal being that the seller can draw in sterling on a London credit opened on behalf of the buyer. The buyer asks his German bank to arrange with its London agent to open the credit, and informs the seller accordingly. The American seller then draws his bill on the London agent of the German bank, and either discounts it at his New York bank or tells his New York bank to collect it. In either case the New York bank forwards it to its own London agent, who presents it to the London agent of the German bank for acceptance, and in due course for payment. In this case there is a decrease in the sterling balance in London of the German bank and an increase in the sterling balance in London of the New York bank.

These examples show the foundation of modern foreign exchange dealings. This consists of the balances held by the banks of one country with the banks who act as their agents in foreign countries, such as the sterling balance in London of the New York bank, and the dollar balance in New York of the London bank.

Frequent mention has been made of the "equivalent rate," but before this can be explained, the operation of the foreign exchange market must be described. It will be realized that every one of the examples cited above ends in an increase or decrease in the balance held by one bank in one country with its agent in another. Were there a complete equilibrium every day in the supply and demand table previously given, these increases and decreases would obviously cancel out. As equilibrium never exists, some banks are always finding that their foreign balances are growing too big, while others find that they are becoming depleted. They then have to buy and sell foreign currencies between themselves, and this is the modern foreign exchange market.

The London Foreign Exchange Market.—Every bank in London has a "dealer" whose job is to watch the size of his foreign balances and to buy or sell foreign exchange accordingly. There are also brokers in London who act as intermediaries between the dealers. One set of brokers will specialize in dollars, another in francs, and so on, so that a dealer wishing to buy and sell dollars knows that there are two or three special brokers whom alone he need approach. Each morning the broker rings up the various bank dealers and quotes the rate; thus for dollars he might call "5 to 5¼," meaning $4.85 to $4.85¼ to the pound. One dealer might want to buy $10,000 to replenish his New York balance, and as he wants them as cheaply as he can get them, he might say he will "take at 5½." Another dealer, with a surplus of dollars, may want to sell, but only "at 5⅛." Then the broker tries to "get a fit," and in the middle of it some more buyers and sellers may come in at varying rates. If the broker has many buyers, he will call the rate "4⅞ to 5⅛," and so shake off some buyers and tempt out fresh sellers, for "4⅞ to 5⅛" means, of course, dearer dollars than "5 to 5¼." So the day goes on, and every time the broker gets a buyer and seller to agree, he drops out at once, leaving them to put the transfer of dollars through between them. The only other thing he has to do is to collect his commission. The important thing is that normally he neither buys nor sells himself; and the "double quotation" is not a buying and selling quotation such as is made by a stock-jobber, but is made in that way for its psychological effect in tempting buyers and sellers to agree.

The actual transfer of dollars is made by cables from the buying and selling banks in London to their agents in New York. By custom, two days after the deal, the one London bank pays the other London bank in sterling for the dollars, while the seller's dollar account in New York is debited and the buyer's credited, the dollars being paid over by the one New York agent to the other.

Rates of Exchange.—The rates at which these deals go through are called "cable rates," for the orders to the foreign agents for their execution are sent by cable. They cannot go beyond the gold points, for bankers would then find it cheaper to correct the size of their balances by an import or export of gold, bought in the one country and sold in the other. They are the rates published in the newspapers, and they are the basic rates for all exchange transactions and remittances made by banks for their customers, *i.e.*, for the "equivalent rates" mentioned above. Some of these can now be described.

(1) *Cheque rate* is the rate at which a bank will buy foreign currency cheques from its customers. If cable rate for dollars is $4.85, cheque rate would be slightly higher, say $4.85⅛—*i.e.*, the bank would insist on buying at a cheaper price or rate than the cable rate of the day. The reasons for this are (*a*) that the bank may want a small margin as an insurance against the risk of the cheque being a bad one; and (*b*) the bank pays sterling for the cheque at once, but does not receive the dollars until the cheque reaches New York and is presented for payment. Meanwhile, the bank is out of its money. When a dollar cheque is not sold, but is handed to the London bank for collection, the customer has to wait for his money until the cheque reaches New York and is paid. He gets his sterling at the cable rate ruling on the day the cheque is paid, less the charge made by his bank for collection.

(2) *Sight rate* is the rate at which a bank will buy foreign currency bills payable at sight. This is governed by the same considerations as the cheque rate.

(3) *Long rate* is the rate at which a bank will buy foreign bills payable some definite period after sight (*see* BILL OF EXCHANGE). Here the bank is out of its money until such time as the bill matures, and the calculation of the rate is best illustrated by an example. Say the bill is for $100, has 90 days to run and the discount rate in America is 4% per annum; then the buyer of the bill only gets $100 at the end of 90 days, which at 4% is the equivalent of $99.01 on the spot. If cable rate on the day of the purchase is $4.85, the sterling equivalent of $100 in three months is not £100÷4.85, but £99.01÷4.85, or £20.8s.3d., for $100 in three months is only worth $99.01 on the spot. The long rate can now be found by setting £20.8s.3d. against the original $100, and by simple division it comes out at about $4.89¾. This roundabout way of calculation has been used to show exactly how and why the long rate is reached. The simpler and more usual method is to calculate directly from the cable rate, the equivalent interest being added thereto, as dollars in three months are cheaper than dollars on the spot. Were an American banker buying a three months' sterling bill, he would deduct the equivalent interest from the cable rate, making "long sterling" $4.80¼. This is because it is sterling that is cheaper, not dollars.

(4) *Forward rates* are the basis of a special market, which was built up to meet the difficulties arising from wild exchange fluctuations prevalent from 1919–26. Just as a cotton spinner can buy or sell "futures," *i.e.*, cotton for delivery on some fixed future date, so can a trader buy or sell foreign exchange from or to his bank for delivery one or two or three months ahead, at the forward rate of the day on which he buys or sells. Once he has

bought, say, forward francs at frs. 120 to the pound, he need not worry if, before he gets delivery and has to pay, the rate goes to 60 or 240. Forward exchange has proved a very real protection to traders against exchange vagaries.

When a bank dealer is notified of a large sale (or purchase) of forward francs by his bank to a customer, he at once buys (or sells) in the market in equal quantities of spot francs. Then he is safe for the day against any big adverse jump in the spot rate, which would, of course, carry the forward rate with it. Just before the close of the day's business, he adjusts his open forward positions. To do this, he buys (or sells) such net amount of forward francs as he has over after taking into account all his bank's sales to and purchases from its customers, and at the same time "undoes" all his "guard" purchases and sales of spot francs by a net sale (or purchase) of spot francs at the closing cable rate of the day. He has thus balanced his forward book for the day.

Forward rates are always quoted in so-many centimes or cents above or below spot. If dealers are buying forward dollars, the forward rate may be a cent or so below spot, and vice versa. The reasons why a forward rate is sometimes above and at other times below the spot rate will be considered later. For the moment, all that need be done is to emphasize the fact that the considerations are totally different from those that govern long rate.

The Theory of the Foreign Exchanges.—It is now time to turn to more theoretical considerations. Why is it that there is a demand for sterling or francs or dollars? The answer is contained in four main rules. (1) Goods naturally flow to the market where prices are highest. (2) Investors turn to the market where they can get the highest and safest return on their money. (3) Bankers and financiers deposit their surplus funds in the centre where, granted adequate safety, they can obtain the highest interest. (4) If a country is losing gold, and/or finds trade and the stock exchange reaching a speculative height, and/or credit becoming "shaky," bankers in that country tend to raise interest rates.

Purchasing Power Parity.—Rule (1) may be regarded as the basis of Professor Cassel's famous "purchasing power parity" theory. This is that if the shipment of gold is forbidden, so that the rates of exchange can move beyond the gold points, the rate of exchange between two countries is determined largely by the internal purchasing power of each country's currency. Thus in 1913, at par, £1=$4.866 and British and American internal prices each stood at 100 (*see* INDEX NUMBERS). For the year 1920, British prices averaged 290 and American prices 230, in round figures. According to the theory, it took £2.9 in 1920 to buy the same as £1 in 1913, and $2.3 to buy the same in 1920 as $1 in 1913. Hence the 1920 parity would not be £1=$4.866, but £2.9=$4.866×$2.3, or £1=$3.86. This theoretical rate of $3.86 Professor Cassel called the "purchasing power parity."

So long as the actual rate was at that point, the British purchaser would find British and American goods equally cheap, but if it moved, say to $3.96, American goods would be the cheaper, for he could then get more than a pound's worth of dollars for his pound. So he would buy American goods, and his banker would have to supply him with dollars out of his New York balance, so that he could pay for them. So his bank's dealer would start buying dollars, and force the rate lower till it reached $3.86, the point of equilibrium, when a pound would buy a pound's worth of dollars and no more. If the actual rate went, say to $3.76, the position would be reversed and Americans would start buying British goods.

The theory holds in a different form when gold shipments are legal and the exchange is kept within the gold points. The Englishman and American alike buy in the cheapest market, and the country where prices are the higher begins to import goods. Purchase of exchange to pay for them drives the rates down to the gold point, gold flows out and the loss of gold forces bankers to contract credit, call in loans and so make traders throw their stocks of goods on the market. This forces down prices at home to the point where home goods become cheaper than foreign, and so restores equilibrium. In the former case the rate is forced to conform to the purchasing power parity, but where the gold standard obtains, it is the purchasing power parity that is forced to conform to the rate.

The following table, dealing with England and the United States, illustrates the approximate character of the theory:—

Date.	Purchasing power parity.	Actual rate of exchange.
April		
1920	$3.78	$3.93
1921	4.10	3.93
1922	4.74	4.42
1923	5.00	4.66
1924	4.57	4.35
1925	4.90	4.79
1926	5.21	4.86

All than can be said is that the two move up and down together; in practice they rarely coincide. Of course, purchasing power parity can never be calculated exactly.

Rule (2), relating to stocks and shares, works out in a similar fashion. It is permissible to connect with this the high level of New York stock prices in the autumn of 1927, and the flow of American money to Europe for investment, which was one of the causes of the European exchanges being forced down to the gold point, so that gold was lost to Europe.

Exchanges, Discounts, Rates and Gold Shipments.—Rules (3) and (4) have been proved over and over again. A banker can obtain interest on his balances with his foreign agents at rates governed by the general level of interest rates in each country, and so, where interest rates rule high, he will let his balances grow, and even add to them by exchange purchases on his own account. For example, he may buy spot exchange and sell forward exchange, and by so doing he will have foreign currency at his command for a definite period. Incidentally, this will make forward exchange cheaper than spot exchange, *i.e.*, if London was buying spot francs and selling forward francs, the forward rate for francs would be above spot. The relative level of interest rates thus partly decides whether the forward rate is above or below spot. It follows from these rules that a rise in interest rates always checks an efflux of gold due to foreign exchanges reaching the gold point. A striking case of this occurred in London in the autumn of 1925. Many American bankers knew in 1924 that England was going back to gold, when the pound would be worth $4.866; so they bought pounds at $4.5, $4.6 and $4.7, knowing they could eventually re-sell at $4.866. When these hopes were realized in April 1925, interest rates in London were high, so they left their money in London. In the early autumn of 1925 interest rates in London were lowered, and American bankers found their money could earn more at home. So back it came, and London lost millions in gold to New York. It was only when London rates were raised again that the loss of gold ceased.

In the autumn of 1927 London was again slightly above New York, and this time it was New York that lost gold. As a matter of fact, the three first rules united in making the exchanges unfavourable to the United States.

In short, adverse exchanges are a sign of (*a*) too high internal commodity and stock prices, and (*b*) too low internal interest rates. They lead to a loss of gold, and in self-protection bankers have to take steps which automatically correct these adverse factors. Equilibrium may take time to reach, but in the long run it is restored.

EXCHANGE MARRIAGE. As workers and potential wives and mothers, all women are valuable to the community of which they are members. For this reason, amongst many primitive peoples a man can only get a mate by compensating the group from which he takes her. This compensation can be in the form of goods or service or of another woman. Though sometimes a woman has much freedom in choosing a husband, where marriageable women are scarce (owing to polygyny or, to restrictive marriage prohibitions) she is more or less at the disposal of her guardian, generally her father or maternal uncle or brother, who may use her as a means of procuring a wife for himself by exchanging her for another man's sister or daughter. In Australia and New Guinea and parts of the Pacific this is the most widely recognized way of arranging marriages. Commonly two men will marry each other's sisters (almost always real, not "classificatory"). If a man has several sisters, he has generally the right to dispose of all of them and so can obtain an equal number of wives; but if there are several of each sex in a family every brother in age order has a right to one sister, though, in Australia, a man will sometimes deprive his sons by exchanging a daughter for a wife for himself. In the island of Erromanga (West Pacific), where there is local exogamy (*see* EXOGAMY), the transaction concerns districts not families. If a man of district A wishes to marry a girl of district B, a girl of his own district, not necessarily his own sister, must be set aside for a return match, and both girls must be approved by the district chiefs.

In other parts of the world marriage by exchange is substituted for "marriage by purchase." If a man is too poor to collect the necessary "bride-price" for a wife, he may seek out another similarly circumstanced and effect an exchange of sisters. This is done to-day in many parts of India, by the Fellahîn of Palestine and by less cultured peoples. Even where "marriage by purchase" is general we may see another form of exchange in the custom, found in East Africa and elsewhere, of regarding the wealth obtained by the marriage of a woman as belonging by right to her brother, wherewith he may obtain a bride.

Among some tribes who normally practise exchange marriage, part of the ceremony consists in what appears to be the paying of a bride-price, which would be superfluous, if the exchange of women were for economic reasons. It is often the case with so-called "marriage by purchase," however, that the woman is not "bought" from her people, but that the exchange of gifts which takes place is of purely sociological not economic significance and has as its object the ceremonial uniting of the groups of bride and bridegroom. In Erromanga, when, after a marriage between two districts, a return marriage is made, part of the "bride-price" paid consists of the very goods which changed hands during the first marriage. Thus in some places the exchange of women may have originated for a similar reason.

In Australia, and among many tribes in India, exchange marriage is definitely associated with the marriage of cross-cousins (*see* COUSIN MARRIAGE). If two men exchange sisters, and if sons and daughters result from each union, then it would be natural for the boy cousins again to marry each other's sisters. This would result in a marriage between people who were doubly cross-cousins and, if persisted in from one generation to another, would create a permanent bond between the two branches.

EXCHEQUER. An English name for an accounting department, used of private as well as of public institutions, but more commonly of the government office receiving and having the care of the public revenues. (Lat. *Scaccarium,* a chess-board or, derivatively, a counting table and, from that, an accounting department.)

As the name of a Government department, we cannot say whether "Exchequer" is older than the 12th century. The Treasury, with which it was in practice joined, dates from before the Conquest and those officers of the Exchequer who were drawn from the Treasury staff can be traced back to Domesday. The word came quite early to be applied to the two jointly, the "lower" Exchequer, or "Receipt," closely connected with the permanent Treasury, being an office for the receipt and payment of money, while the "upper" Exchequer (the *scaccarium* proper) was a court sitting twice a year to regulate accounts and closely related to the Curia Regis, and is thus probably on the Norman pattern. The lower Exchequer was conditioned in its development by the use of tallies (*see* TALLY); the upper, as its name implies, was based on the use of the abacus, or counting-board, for reckoning, such a contrivance being almost universal before the introduction of Arabic numerals, which did not become common in England till the 16th century. Our earliest information about the Exchequer itself, apart from that afforded by the pipe rolls, rests on a treatise (*Dialogus de Scaccario*) written in the latter part of the reign of Henry II. by Richard, bishop of London and treasurer of England. His father, Nigel, bishop of Ely, had been treasurer to Henry I., and nephew of that king's great financial minister, Roger, bishop of Salisbury. Nigel is said to have reconstituted the Exchequer after the troubles of Stephen's reign upon a model inherited from his uncle.

The Angevin Exchequer.—The sessions seem at first to have been confined to the actual times when the court sat at the "chess-board," round which were grouped the "barons," officials and accountants. At the head of this table were the great officers of State; except the treasurer, who sat on the right with the Exchequer clerks below him: on the left was the calculator, and at the bottom appeared the officials whose accounts were to be audited. Of the officers of State, the justiciar was normally the president, in the king's absence; the chancellor was responsible, as keeper of the seal, for all writs and summonses; the two chamberlains, lay colleagues of the treasurer, shared with him the duty of receiving money and keeping the records and other contents of the Treasury; the marshal, a subordinate of the constable, was responsible for the custody of prisoners and of the accountants' vouchers. The treasurer charged accountants with their debts and dictated the great roll of accounts ("pipe roll"), which was written by his scribe, the chancellor's scribe copying from this a duplicate (the "chancellor's roll"). The calculator worked out the sums on the Exchequer table (*abacus*) by means of counters. Other subordinates were the *Magister Scriptorii* and the chancellor's clerk (later chancellor of the Exchequer) who settled the form of all writs and summonses, charged the sheriff with all fines and amercements, and acted as a check on the treasurer in the composition of the pipe roll.

In the lower Exchequer (the "Receipt"), the staff was divided between the treasurer and chamberlains, the clerical members being under the former, the lay under the latter. The money brought in by the royal accountants was counted by the "four tellers," weighed by the "pesour" (a knight) and assayed by the "melter," receipts being recorded by means of wooden tallies cut and split by the tally cutter, one half going to the payer while the other was retained at the Exchequer to prevent fraud. Record of moneys issued was mainly secured by filing the warrants for payment (writs under the great seal) as they were honoured. Early in Henry II.'s reign written records of the tallies (rudimentary receipt rolls) began to be kept in addition to the originals; issue rolls were also used later for money paid out, but the old tally and warrant system continued throughout the history of the department. At the Receipt the treasurer was represented by a clerk (later clerk of the pells), and each of the chamberlains by a knight (later the "chamberlains of the receipt"); these three had joint control of the Treasury. In both upper and lower Exchequers were ushers.

The business of the ancient Exchequer was mainly financial, though some judicial business connected with the accounts was also done. The principal accountants were the sheriffs, who were bound, as the king's chief financial agents in each county, to give an account of their stewardship twice a year, the state of their accounts being "viewed" at Easter, when they made their first "profer," and audited on the pipe roll at Michaelmas. The fixed revenue consisted of the farms of the king's demesne lands within

the counties and of certain boroughs which paid annual sums as the price of their liberties. Danegeld, though regarded as fixed revenue, was infrequently levied after Henry II.'s accession, but there were rents of assarts and purprestures, mining and other royalties. The casual revenue consisted of the feudal incidents (escheats, wardships and marriages), of the profits of justice (amercements, and goods of felons and outlaws) and of fines or payments made by the king's subjects to secure grants of land, wardships and marriages, and of immunities, and to hasten (or sometimes to delay) justice. Besides these there were the revenues arising from aids and scutages of the king's military tenants, tallages of the Crown lands, customs of ports and special "gifts," or general assessments made on particular occasions. For the collection of all these the sheriff was primarily responsible, though in some cases debtors and accountants dealt directly with the Exchequer and were bound to make their appearance in person on the day when the Sheriff accounted.

The farms of demesne lands were originally for the most part paid in kind (though payments in assayed silver are found in Domesday Book), but at some date, possibly in the administration of Roger of Salisbury, the inconvenience of the earlier arrangement led to payment in cash. The rapid deterioration of a small silver coinage gave rise to attempts at maintaining the value of cash payments, first by a scale reduction for wear, then by substitution of payment by weight for payment "by tale," and finally by the reduction of payments of most farms of the shire to their pure silver value by means of an assay. The casual revenue was still paid by tale, and for the determination of its amount it was necessary for the Exchequer to receive copies of all grants made in the Chancery on which rents were reserved or fines payable: these were known first as *contrabrevia* and later as *originalia*. The profits of justice were notified by the delivery of similar "estreats" from the justices' records from an early date; and, while for certain minor casualties the oath of the sheriff was at first perhaps the only security, later they were frequently determined by means of inquisitions. Exchequer business might be transacted anywhere in England; the original meetings were at Winchester, later they took place at Westminster as a rule but occasionally, even in the 14th century, elsewhere.

Developments in the 13th and 14th Centuries.—The Angevin "course" remained the ideal of the Exchequer for six centuries: and its lineaments were never completely effaced, though the vast increase of business soon meant that the machinery had to be stretched if it was not to break down. Great officers of State ceased to attend personally: even under Henry II. we gather that all, except the treasurer and chancellor, had deputies: and under Henry III. the chancellor was represented by his clerk who became "chancellor of the Exchequer." On the other hand new officials emerge, notably the four permanent official barons and the king's and lord treasurer's remembrancers. Two "memoranda rolls" of these remembrancers survive for John's reign and show that the Exchequer already sat regularly except during vacations, that memoranda were made of business reserved for attention at subsequent sittings, and that this business had begun to be arranged systematically. During the 13th century their functions, originally very similar, became gradually differentiated, the memoranda rolls developed so that they formed a complete record of a large part of the Exchequer business, and by the Ordinance of 1323–26 the remembrancers' precise duties were defined. Henceforward the king's remembrancer was more particularly concerned with the casual, the treasurer's with the fixed revenue: the former put all debts in charge, while the latter saw to their recovery, when they had found their way on to the great roll. Hence the preliminary stages of each account, the receiving and registering of the king's writs to the treasurer and barons and the drawing up of all particulars of account, lay with the king's remembrancer, and he retained the corresponding vouchers, a collection which, though much diminished, is still one of exceptional size, diversity and interest. The treasurer's remembrancer exacted the "remanets" of such accounts as had been enrolled, as well as reserved rents and fixed revenue, and so became closely connected with the clerk of the pipe. Before the end of the century these three offices had separated into different departments.

Judicial Procedure at the Exchequer.—We must turn aside here to mention a 13th century development at the Exchequer which was only indirectly concerned with accounting. By about 1250 convenience had led to the establishment of something like separate machinery, and definitely separate records for legal cases which arose out of accounts and which, in the earliest times, we find among the ordinary memoranda. In the case of Jewish affairs we have a curious mixed arrangement by which, though receipts from Jewish sources passed through the ordinary machinery of the lower Exchequer, there was apparently no recognized organization for audit. In these circumstances a special *Scaccarium Judaeorum*, whose records are known to us as the Jewish plea rolls, dealt with most of the financial business, other than that of actual receipt, and at the same time acted as a court for the trial of all cases, both Crown and civil, in which Jews or Jewish business were concerned. The point of contact with the Exchequer was that, all Jews and their property being at the absolute disposal of the Crown, no case arising from their business was without a potential interest for the royal financial administration. Parallel to this was the organization of a department of pleas which, while it had nothing to do with financial business covered by the ordinary machinery of the memoranda roll, and nothing with normal "pleas of the crown," relieved pressure by taking cognizance of the increasing bulk of disputes arising out of the conduct of the royal accounting together with all cases affecting Exchequer officials. The *Scaccarium Judaeorum* ended with the expulsion of the Jews in 1290, but the Exchequer of Pleas, though it continued to be staffed by Exchequer officials, became a court of civil pleas like any other and was ended only by the Supreme Court of Judicature Act of 1873.

Other Modifications in Exchequer Machinery.—To return to the 13th century—the increasing length and variety of accounts led to various other efforts at reform besides those already mentioned. Even before Henry II.'s death, two problems had become apparent: the great roll had to be cleared of "desperate," or bad, debts in the twenty-eighth and thirty-third years, and the rapidly increasing number of amercements in the various courts was clogging the whole machinery. The 13th century saw a strenuous effort to meet the new conditions: its stages are marked by the reforms of 1236–42 (no statute), and the statutes of 1270 and of Rhuddlan in 1284; its termination by the codification of Exchequer practice (already well established in many respects) in the Stapledon Ordinances, 1323–26. By 1242 the farms of the counties and boroughs had been re-valued and the demesne lands removed from them and let to farm for a term of years; the estreats were no longer entered on the great roll in detail, the sheriff being charged on each estreat roll and only actual payments recorded on the great roll itself; while a new form of tally allowed the sheriff to pay large totals into the Exchequer in his own name instead of having to get a tally for every small debt. This simplified work at the Exchequer enormously: the machinery had stretched. The statute of 1270 codified the new procedure with regard to estreats; that of 1284 dealt with farms of counties, the new form of tally and, after earlier experiments, established a special "exannual roll" in which desperate debts were recorded, in order that the sheriff might be reminded yearly without their overloading the pipe roll.

But these were not the only changes in the 13th century. Thus, we note the appearance of a new system of anticipating revenue, sheriffs being frequently ordered to pay out locally the greater part of their receipts; and the "assignment" of tallies for moneys not yet paid in became common and was a feature of Exchequer procedure throughout its subsequent history. Again, under Henry III. and his son a large accession of financial business arose from the "foreign accounts," that is to say, the accounts of national services which, naturally, were not included among those of the counties and which under Henry II. had not formed part of Exchequer business; for in his reign such expenses as appeared on the pipe roll were paid by sheriffs or by bailiffs of "honours," and the spending departments frequently drew their supplies

only indirectly from the Exchequer, though in the course of the following (13th) century the Exchequer gradually acquired partial control of these national accounts. Finally we have to record the appearance before 1242 of "escheators," and from then onwards the accounts of these and of the officials of the customs, subsidies and wardrobe also occupy an increasingly important position in the national revenue. During the reign of Edward I., the wardrobe account became unmanageable, since it not only financed the household, army, navy and diplomatic service, but received money direct from accountants without its passing through the Exchequer. (*See* WARDROBE.)

Enough has been said to show that the 13th century was a period of rapid growth in many directions, and the reform of 1323–26, referred to above, codified and rounded off those already in existence. It greatly increased the number of "foreign accounts" by making the great wardrobe (the storing department), the butler, purveyors, keepers of horses and clerk of the "hanaper" of the chancery (who took the fees for the great seal) and the various ambassadors, directly accountable to the Exchequer. At the same time the sheriffs' accounts were expedited by further simplification of the great roll, and by the appointment of a special "foreign apposer" to take the account of the "green wax," or estreats, so that two sides of the sheriff's account could be dealt with simultaneously. An extra baron was also appointed to cope with the increase of business but this was only a temporary expedient and the fifth, or cursitor baron, does not appear as a permanent official until James I.'s reign. The whole business of foreign accounts was transferred to a separate building where one baron and certain auditors spent their whole time in settling the balances due on the accounts already mentioned, as well as those of royal lands not let to farm, of Wales, Gascony and Ireland, of aids (clerical and lay), of temporalities of vacant bishoprics, abbeys, priories and dignities, of silver and tin mines, of ulnage and so forth. The balances on these were accounted for in the Exchequer itself, and arrears still entered on the pipe roll, but the preliminary accounts were filed by the king's remembrancer, and the actual accounts enrolled separately by the treasurer's remembrancer on the "roll of foreign accounts," a supplement to the pipe roll.

Reform in the rest of the 14th century apparently worked along the lines laid down in 1323–26, with the addition of some attempts about 1360 to draw up something like a balance sheet of revenue and expenditure—a notion foreign, in general, to mediaeval accounting methods.

End of the Mediaeval Period.—The next important change came at the end of the 15th century, following a period during which assignment and other expedients for patching up the royal finances ran wild and the issue roll ceased to exist. It was inaugurated by Henry VII., who introduced summary methods of audit in certain connections, while carefully and personally supervising receipt and expenditure. In the next reign the dissolution of the monasteries led to the setting up of independent financial bodies —the Courts of Augmentations and of First Fruits—with wide powers and with new methods: and although these, in 1554, became departments of the Exchequer, a new act set up in 1560, in addition to the exchequer auditors, two new and independent "auditors of the prests" (predecessors of the commissioners for auditing public accounts, who were set up in 1785), to take certain specified accounts, such as those of clerks of the works, the treasurer of ships and the master of the ordnance, the clerks of the hanaper and of the great wardrobe and (later) the customs. These new authorities followed improved methods of auditing, though it was only by degrees that the various stages of "declaring" an account were worked out and the final stage of development was not reached until the treasurership of Juxon (1636–41). By the end of the 17th century a system had been evolved of "declaring" at the Treasury accounts presented in triplicate, one (on paper) being returned to the office of the auditors, while of the other two (on parchment) one went to the accountant and one was passed for enrolment through the offices of the two remembrancers to that of the clerk of the pipe, in order to secure the levying of any "remanets" or "supers" by process of the Exchequer.

Modern Developments.—It will be observed that by this device the connection with the old Exchequer machinery was maintained, though in effect the control over public accounting, asserted with so much trouble in the 13th and 14th centuries, passed from it to the Audit Office. Similarly when, in the 17th century, the other great step towards modern methods was accomplished by the putting of the office of treasurer into commission, the old machinery of the lower Exchequer, with its tallies, receipt rolls and a multitude of added apparatus, continued to function under the direction of the new body. This survival of the old machinery continued for 150 years and there were even additions of new administrations to which the name of Exchequer attached; there was, for instance, an Exchequer court of equity, established in the reign of Elizabeth, whose registrar was the king's remembrancer; and in the same reign there was added to the Exchequer's departments one for the audit of land revenue. It was not until the 19th century that a series of acts swept away one by one all these departments leaving only the name of the Exchequer and those of one or two of its officials as relics of the past.

Of these acts the most important from our point of view was that of 3 and 4 William IV. cap. 99; this by removing the sheriffs' accounts from its competence ended the series of pipe rolls and in effect destroyed the last vestige of that *Scaccarium* with which the tale began. (H. JE.; M. H. M.)

FROM THE ACT OF 1834

The Exchequer Act, 1834, swept away the cumbrous mediaeval procedure and the expensive sinecures that had survived at the exchequer till then. A simplified system of accounting was adopted; the great triple-locked chests in which the public money had been put away became unnecessary when accounts were opened at the Banks of England and Ireland for the Consolidated Fund; and for the work which remained to be done a single comptroller of the exchequer with a small clerical staff sufficed, the comptroller's duty being to see that sums were issued from the Consolidated Fund only to the amounts and for the purposes authorized by parliament.

For a long time the greater part of the issues from the exchequer had been made not by way of final payment to the people entitled to public money, but by way of advances to the paymasters of the departments concerned (the paymaster general of the Forces, the treasurer of the Navy and others), though a few payments (chiefly salaries and pensions) had continued to be made direct from the exchequer. After 1834 these direct payments ceased, and *all* issues from the Consolidated Fund were made to the paymasters and similar intermediaries. In 1836 the paymaster general of the Forces, the treasurer of the Navy and the treasurer of the Ordnance were amalgamated into one post, and in 1848 this post was combined with the paymaster of civil services into a single paymaster general for all voted services. Since then departments have drawn upon the paymaster general for their expenditure as if he were their banker; the drafts are often for advances to officers (sub-accountants) who are responsible for making the actual payments.

Exchequer and Audit Department, 1866.—The business of authorizing issues from the exchequer in conformity with parliamentary authority, whatever its constitutional importance, did not make work for a separate department. As a result of the recommendations of the Select Committee on Public Moneys (1856–57), while the functions of the exchequer were maintained substantially as under the act of 1834, the department was amalgamated with the audit department by the Exchequer and Audit Departments Act, 1866. In the constitutional system the same kind of independence was required of the comptroller of the exchequer as of the head of the audit office, who had to conduct the appropriation audit and discover *ex post facto* whether the expenditure of public departments had been in conformity with the terms of the parliamentary votes placed at their disposal.

At the head of the new Exchequer and Audit Department was placed a Comptroller General of H.M.'s Exchequer and Auditor

General of the Public Accounts. He is appointed by, but is not a servant of the Government; he is a statutory officer with responsibilities primarily to parliament, but also, in respect of some of his functions as auditor, to the Government.

The Consolidated Fund.—All the revenue and the proceeds of loans and other public receipts (with certain very restricted exceptions) have to be paid to the Consolidated Fund (originally created by an Act of 1787). Consequently all the expenses of Government have to be met from that fund, which is in the hands of the exchequer; whence balances to its credit at the Banks of England and Ireland (formerly at the Head Office in Dublin, now at the Belfast Branch) are commonly called the exchequer balances. Issues cannot be made from the exchequer account at the Bank of England without the consent of the comptroller and auditor general, and that consent he gives only by authority of parliament. Parliament is thus in a position to stop the machinery of Government by refusing supplies, and can thereby enforce its will on the Government. But for the intervention of an independent officer, the Government might go on spending in defiance of a parliamentary refusal of supplies, leaving the illegality to be reported long after on completion of the audit.

In order to safeguard certain services from the hazards of a political vote, permanent statutory authority is given for the exchequer issues required for them. These, known as Consolidated Fund services, include the national debt charges (interest, maturities and sinking fund), the king's civil list, the salaries and pensions of the judges, and some other items. The issues for the internal debt are the more effectually safeguarded in that they are made direct to the Bank of England (or of Ireland) without passing through the hands of the executive Government at all.

"Ways and Means" and "Supply."—The rest of the expenditure is provided for by annual votes. When parliament votes and appropriates money, it is really attaching conditions to the issue of money from the exchequer. In parliamentary procedure the two processes, the authorization of issues and the appropriation of the sums to be issued, are kept distinct. The former is initiated in Committee of Ways and Means, and the latter in Committee of Supply. The resolutions in Committee of Ways and Means have in themselves no operative effect. The comptroller and auditor general will only allow issues from the exchequer on the authority of an act of parliament. An act (called the Consolidated Fund Act) is always passed before the 1st April (when the new financial year begins) authorizing the issue of a sum equal to the vote on account and any other vote previously passed in Committee of Supply. The credit or power given by act of parliament to the Government to draw money from the exchequer is commonly called "Ways and Means."

Appropriation Act.—It is a constitutional convention that the issue of money from the exchequer is never authorized by this procedure without the purposes to which it is applicable being prescribed by parliamentary votes. The votes are regarded as operative even when they are no more than resolutions reported from Committee of Supply. But that is only so up to the end of the session, and therefore before the prorogation by which the session is ended there must be an act (the Appropriation Act) giving statutory authority for all the votes in supply. The Appropriation Act grants Ways and Means exactly sufficient, with those authorized by the Consolidated Fund Act (or Acts, for there are sometimes several), to meet the expenditure authorized by all the votes in supply of the session, and it then proceeds to direct the appropriation of the issues from the exchequer in accordance with the votes (set out at length in schedules). It is the regular custom always to grant Ways and Means equal to the supplies voted. But there is no constitutional reason why the Ways and Means should not be less.

The Treasury (fortified with a "royal order" under the king's sign manual) applies to the exchequer for issues of money as and when required, and, in applying, specifies the particular vote or Consolidated Fund service for which each sum is destined. But this is a mere expression of intention; the treasury is not bound actually to spend those particular sums in the manner indicated. They are merely *advances* to the paymaster general. The Government must conform strictly to parliamentary authority, as expressed in the acts charging the Consolidated Fund and in the votes in Supply, but only in its expenditure *as a whole*, and this conformity is enforced by the comptroller and auditor general not through his control of exchequer issues but through his subsequent audit. In complying with an application for issues from the exchequer, he is concerned only to know that statutory authority exists for the *total amount* of the issues applied for.

Parliamentary "Doles."—Parliament may be regarded as doling out money to the Government by means of the Consolidated Fund Acts and the Appropriation Act, each successive instalment giving the Government so many months of life. The responsibility of the Government to parliament is so well recognized that the very purpose of exchequer control, as the constitutional sanction of parliamentary government, is apt to be forgotten or overlooked. Occasionally a Government (like the Liberal Government engaged in 1910 in a conflict with the House of Lords) may deliberately ask for Ways and Means in small instalments in order that the House of Commons may keep a hold over a possible alternative Government, but this is rare.

Apart from its constitutional purpose exchequer control provides incidentally a very convenient index of the state of the public finances. As all receipts from revenue and loans are paid into the exchequer, and the money for public expenditure is issued out, the exchequer receipts and issues at any stage of the financial year show substantially the financial position up to date. Since the practice is to indicate the sources of the receipts under the principal heads of revenue (customs, excise, death duties, stamps, income tax, supertax, etc.) and the application of the issues to the several Consolidated Fund services and votes, it is possible to compile a detailed account showing the progress of each head of revenue and expenditure. But this account would differ from a true account of revenue and expenditure on account of variations in the balances held on the one hand by the revenue departments and awaiting payment into the exchequer, and on the other hand by the paymaster general and the sub-accountants of all the public departments and awaiting expenditure.

The Annual Balance.—For the purpose of calculating the surplus or deficit for the year, revenue and expenditure are calculated on the basis of exchequer receipts and exchequer issues. The justification for this convenient practice (which makes the surplus or deficit finally ascertainable on the very day the financial year ends) is that balances are invariably kept down as low as is practicable. In fact a change in balances when it occurs may be regarded as a real financial requirement of the public service on the same footing as actual expenditure, and it is quite right to budget for such a change. To show the amount of the surplus or deficit, the receipts and issues on capital account (such as the raising and repayment of loans, and expenditure chargeable by special acts to loans) are shown separately from those items which properly belong to the revenue and expenditure of the year. The new sinking fund (1923) is included in the expenditure, and since 1920 any further net sum applied from revenue to the reduction of debt has been similarly treated. Formerly a surplus used to be applied to the redemption of debt *after* the financial year in which it was realized, and this was not included in expenditure.

On any voted service the Government cannot spend more than parliament has allowed and may spend less, and any foreseen excess is covered by supplementary votes, accompanied by grants of the corresponding Ways and Means. On the votes as a whole there are invariably savings, the total of which is substantial. Therefore a part of the Ways and Means is not needed, and in the absence of parliamentary appropriation cannot be put to any legitimate use. The practice is to "surrender" these balances to the exchequer. Where possible this is done by a process called "write-off." The exchequer is deemed to issue a sum equal to the balance to be surrendered, and at the same time the paymaster general is deemed to have paid an equal sum from the vote to the exchequer. The settlement is effected by book entries without any actual payment. The result is that the exchequer issues approximate to the true expenditure from votes.

The issues for the purposes of any vote on which the savings in the year are substantial are kept down approximately to the amount actually needed ("short issue"), but where the savings are small the whole amount voted is usually issued. The surrender of balances by write-off can only be completed in the following financial year when the audit has disclosed the exact amount of the savings.

The discrepancy between the account of revenue and expenditure derived from the exchequer receipts and issues, and the true account disclosed by the ultimate audit, while by no means negligible, is not ordinarily large. But during the World War and for some years afterwards the inclusion of huge commercial accounts in the financial system resulted in exaggerated differences. The following comparison shows the position for a series of years (in £ millions):

	1921–2	1922–3	1923–4	1924–5	1925–6
Exchequer Receipts	1124·9	914·0	837·1	799·4	812·1
Exchequer Issues	1079·2	812·5	788·8	795·8	826·1
Surplus (+) or Deficit (−)	+45·7	+101·5	+ 48·3	+ 3·6	− 14·0
Revenue Net Receipts	1119·8	911·2	838·3	804·9	811·2
Audited Expenditure	1053·2	822·0	799·9	798·9	828·7
Surplus (+) or Deficit (−)	+66·6	+ 89·2	+ 38·4	+ 6·0	− 17·5

EXCHEQUER BILLS. The exchequer bill was the credit instrument in which the principal part of the floating debt of the British Government used to be embodied, till its place was taken by the modern treasury bill in 1877.

The exchequer bill was an obligation of the exchequer issued by direction of the Treasury. It was a negotiable instrument transferable by endorsement. It was sometimes for three months, sometimes for one year, sometimes for several years. Its special characteristics were (1) that the holder could use it during its currency (or during a specified part of its currency) in payment of taxes or other sums due to the exchequer, (2) that interest accrued on it from day to day at rates notified by the Treasury from time to time in the *London Gazette*. Sometimes holders were entitled to demand cash for the bills; for example, the holder of a five-year bill might have the option of demanding payment in cash at intervals of 12 months. The original exchequer bills of 1696 were payable at any time on demand, like bank notes.

The right to hand in bills in payment of taxes was in practice equivalent to a right to demand payment in cash. In order to prevent bills from being presented to an inconvenient extent, the Treasury relied on its power over the rate of interest. If the bills were quoted in the market at a discount, that meant that it was profitable to the holders to present them (or to sell them to taxpayers to be presented). The Treasury would then raise the rate of interest high enough to induce holders to keep them.

Exchequer bills were first issued in 1696, when Charles Montagu was chancellor of the exchequer. In the course of the 18th and 19th centuries they came to be issued under various authorities: (1) Supply bills were authorized as part of the permanent national debt, and were regularly renewed as they fell due. (2) Deficiency bills were issued whenever money was needed to make up the charge on the consolidated fund at the end of a quarter (including the interest on the funded debt), and had to be repaid in the ensuing quarter. (3) Bills were issued in anticipation of certain taxes (especially the malt and sugar duties and land tax). (4) From 1829 onwards the practice was adopted of authorizing temporary borrowing on exchequer bills in the Consolidated Fund Acts and the Annual Appropriation Act. These were known as ways and means bills, and took the place of the bills in anticipation of taxes, which were not resorted to after 1831. (5) Exchequer bills were issued to raise money to be lent from the exchequer to local authorities and others for the construction of public works. This system has been replaced by the local loans fund, financed by issues of local loans stock. *See* National Debt.

EXCHEQUER BOND: *see* National Debt.

EXCISE, a word derived through the Dutch *excijs* or *accijs*, from late Latin *accensare*—to tax (cf. *census*), meaning in British law any branch of the revenue placed by statute under the aegis of the commissioners of excise. In modern times, however, the term generally connotes a tax on articles of home manufacture in contradistinction to customs duties, which are levied on certain articles imported. Under the Tudors the sources of English revenue had been the anxious concern of the sovereign: the basis of taxation had remained unaltered for some three hundred years. Intercourse with Holland during the reigns of Elizabeth and James I. had familiarized statesmen and others with the system of excise duties in operation in the Low Countries and as early as 1626 an abortive proposal was made for their introduction into Great Britain. On the outbreak of the Civil War parliamentary need of money became acute and owing to the system of farming the tonnage and poundage for long terms it was impracticable to amend or add to those duties. The excise system, however, managed as it was by a board of commissioners, afforded a system of taxation which could be extended almost indefinitely at the shortest notice. Accordingly a parliamentary ordinance was enacted (July 26, 1643) imposing excise duties on a great variety of articles. The system was admittedly tentative and a succession of ordinances issued from parliament modifying the various taxes from time to time. It is to be noted that the early ordinances imposed excise duties on many foreign articles. Charles I. was not long in following the example of parliament and in the counties which remained loyal excise was collected on his behalf. Throughout the commonwealth the excise duties were regarded as temporary, but at the restoration the revenue of the country came under review, and as for some years past the old feudal revenues had fallen into desuetude it was necessary to find a permanent substitute. This the growing revenue of the excise provided. Half the excise revenue was definitely allotted to Charles and his heirs for their personal revenue, and half, termed the "temporary" excise, was voted him for life, and after the revolution went to form part of the ordinary revenue of the country. This arrangement continued until 1787 when, on the formation of the "consolidated fund," the whole of the excise was transferred to the State (27 Geo. III., cap. 13).

At its inception the excise revenue was placed under commissioners but for some time it was farmed out for short periods on the old system. With the restoration, farming was gradually abolished, though in some of the more distant counties the excise farm continued for some considerable time. Farming the revenue

was open to the objection, among others, that it was inelastic, it being difficult to vary the various duties during the continuance of the farm. At the same time, the restoration placed Charles in a difficult position with regard to the thousands of claims on his bounty made by adherents of the Stuart cause. The customs and excise services formed a very useful and welcome field for paying off these debts, as the hundreds of offices, small and great, were all available and were filled by patent or by direct Treasury nomination. At the revolution, William availed himself of the same facilities and by the end of his reign farming the excise had practically disappeared from the English fiscal system.

In Scotland, excise dates from Jan. 1644, when the first act was passed by the Edinburgh parliament. For many years it was collected with great difficulty, particularly in the Highlands, and farming was the rule. At the union, however, the English system was adopted, though both Scotland and Ireland retained their separate boards of commissioners. The United Kingdom excise was consolidated under one management in 1823 (4 Geo. IV., cap. 23).

Walpole and Pitt.—Walpole's famous excise bill of 1733 was introduced with a view to checking the frauds in the customs revenue from tobacco, and it included a system of bonding. Owing, however, to opposition raised throughout the country by Walpole's enemies, the bill had to be abandoned and the system of bonded warehouses received a set-back for 70 years. Pitt introduced many changes, giving the excise the collection of the wine and tobacco duties, while all through the 18th century the excise service was responsible for duties on many foreign articles, which necessitated the employment of revenue cutters, riding officers and other officials, and duplicated to a very large extent the establishment of the customs service.

With the coming of the 19th century "excise" gradually became associated with duties on articles of home manufacture, together with the revenue derived from licences to manufacture or deal in those articles, and also sundry other licences conferring certain classes of privileges. Up to the middle of the 19th century, and more particularly as a result of the Parnell commission of excise enquiry (1833–39), numerous articles were withdrawn from the tariff and by the end of the century the major part of the excise revenue was derived from spirits and beer. The Entertainments Duty was first levied in 1916, and the Betting Tax ten years later.

In the early 'eighties the warehousing systems of the customs and excise services were assimilated (44/5 Vic. cap. 12), and in 1889 a proposal was mooted for amalgamating the two departments. The scheme was shelved for the time being, mainly owing to the fact that the inland revenue board included the old board of stamps and taxes as well as excise, which had been amalgamated in 1849. In 1909, however, the excise was amalgamated with the customs under the board of customs and excise.

EXCITATION (*see* CHRONAXIE). Excitation is sometimes used in physics to describe the process of electrification (*see* ELECTRICITY) and also the production of X-rays. (*See* X-RAYS, NATURE OF.) The term is used in physiology in connection with stimulation of muscle and nerve fibre.

EXCOMMUNICATION means the judicial exclusion of offenders from the rights and privileges of the religious community to whom they belong (Lat. *ex*, out of, away from; *communis*, common). The history of the practice may be traced through (1) pagan analogues, (2) Hebrew custom, (3) primitive Christian practice, (4) mediaeval usage, (5) modern survivals in Christian churches.

Pagan Analogues.—Among these are the Gr. χερνίβων εἴργεσθαι (Demosth. 505, 14). The exclusion from purification with holy water of an offender whose hands were defiled with bloodshed. (Aesch. *Choeph.* 283, *Eum.* 625 *seq.* Soph. *Oed. Tyr.* 236 *seq.*) The Roman *Exsecratio* and *diris devotio* was a religious curse calling down divine wrath upon enemies. The Druids claimed the right of excluding offenders from sacrifice (Caes. *B.G.* vi. 13). Primitive Semitic customs recognize that a ban or taboo (*herem*) restricts contact with the banned person. Impious persons might be devoted to utter destruction.

Hebrew Custom.—In a theocracy excommunication is both a civil and a religious penalty. In the N. Test. the word ἀνάθεμα is the Septuagint rendering of the Hebrew *herem* (1 Cor. xvi. 22, Gal. i. 8–9, Rom. ix. 3). The word means "set apart" (*cf.* ḥarem), and does not distinguish between things devoted to God and things devoted to destruction. Lev. xxvii. 16–34 defines the law for dealing with "devoted" things. "None devoted shall be ransomed, he shall surely be put to death." Whole cities or nations might be devoted to destruction by pronouncement of a ban (Num. xxi. 2.3, Deut. ii. 34, iii. 6, vii. 2). Israelites may fall under the curse (Judges xxi. 5.11). A milder penalty was temporary separation (*niddah*), prescribed for ceremonial uncleanness. This was the ordinary form of religious discipline. Both major and minor forms are recognized by the Talmud. The lesser (*niddah*) involved exclusion from the synagogue for 30 days, and other penalties, and might be renewed. The major excommunication (*herem*) excluded from the Temple and from all association with the faithful. Spinoza was excommunicated (July 16, 1656) for contempt of the law (Selden, *De jure nat. et gen.* iv. 7). *See* also the *Exemplar Humanae Vitae* of Uriel d'Acosta. The practice of the Jewish courts in N. Test. times may be inferred from Luke vi. 22, John ix. 22, xii. 42 where exclusion from the synagogue is a recognized penalty, probably inflicted on those who confessed Jesus as the Christ. John xvi. 2 ("Whosoever killeth you") seems to point to the major penalty. The Talmud says that the judgment of capital cases was taken from Israel 40 years before the destruction of the Temple, where "40" is probably a round number.

Primitive Christian Practice.—The use of excommunication as a form of Christian discipline is based on the teaching of Jesus and on apostolic practice. Matt. xviii. 15–17 prescribed a threefold admonition, first privately, then in the presence of witnesses (*cf.* Titus iii. 10), then before the Church. The tone of the passage when compared with the disciplinary methods of the synagogue indicates that it was intended to introduce elements of reason and moral suasion in place of sterner methods. Its aim is the protection of the Church rather than the punishment of the sinner. In the *locus classicus* on this subject (1 Cor. v. 5) Paul refers to a formal meeting of the Corinthian church at which the incestuous person is "delivered unto Satan for the destruction of the flesh that the spirit may be saved in the day of the Lord Jesus." These mysterious words imply: (1) a formal ecclesiastical censure, (2) a physical penalty, (3) the hope of a spiritual result. There is a reference in 2 Cor. ii. 6–11 to a case of discipline which may or may not be the same. 1 Tim. i. 20 refers to the excommunication of Hymenaeus and Alexander. 1 Cor. xvi. 22, Gal. i. 8, 9, Rom. ix. 3 refer to the practice of regarding a person as anathema. These passages seem to point to exclusion from church fellowship rather than a final cutting off from the hope of salvation. In the pastoral letters there is already a formal and recognized method of procedure. 1 Tim. v. 19, 20 requires two or three witnesses in the case of an accusation against an elder and a public reproof. Tit. iii. 20 recognizes a factious spirit as a reason for excommunication after two admonitions (*cf.* Tim. vi. and 2 John v. 10). In 3 John v. 9–10 Diotrephes appears to have secured an excommunication by the action of a party in the Church. It is clear that within the N. Test. there is development from spontaneous towards strictly regulated methods, and that excommunication is for protective rather than punitive purposes.

Mediaeval Usage.—The writings of the Fathers supply evidence that two degrees of excommunication, the ἀφορισμός and the ἀφορισμὸς παντελής were in use soon after the apostolic age. The former involved exclusion from the eucharist and from the eucharistic service, though not from the "service of the catechumens" and was the usual punishment for light offences; the latter involved "exclusion from all church privileges" (Bingham *Antiquities*, xvi. 2, 16). From some sins, such as adultery, the sentence of excommunication was in the 2nd century regarded as παντελής in the sense of being irrevocable. The important controversy associated with the names of Zephyrinus. Tertullian.

Calistus, Hippolytus, Cyprian and Novatian turned on whether such sins as theft, fraud, denial of the faith were "irremissible." The stricter party held that there should be no restoration to church fellowship even in the hour of death.

EMPLOYMENT OF EXCOMMUNICATION

A new chapter in the history of Church censure began with the imperial edicts against heresy, the first of which, *de summa trinitate et fide catholica,* dates from 380. From that time excommunication exposed a man to serious temporal risks. The temptation to wield it as an instrument of secular tyranny proved irresistible. During the next thousand years the developments of the practice are perversions of the New Testament standards. The magistrate becomes the excommunicating official (Synesius A.D. 410; *see* Bingham, *Antiq.*). Gregory the Great rebukes a bishop for using excommunication for private ends (*Epist.* ii. 34). The penalty became common and was dreaded for superstitious reasons (Haddan and Stubbs, *Councils and Documents* iii. 1737). Morinus, *De poenit* x. c.q., refers to excommunicating the dead. Pope Gregory V. (998) excommunicated France, Gregory VII. (1102) excommunicated Germany, Innocent III. (1208) excommunicated England, and Adrian IV. (1155) Rome itself. Recklessness was characteristic of the language used (*cf.* Burton, *History of Scotland,* vol. iii. 317 *seq.,* and also the often quoted curse of Arnulphus of Rochester). An instance of excommunication by "bell, book and candle" occurs about 1190.

Modern Survivals in Christian Churches.—At the Reformation the development of discipline took various lines. In the Anglican Church the bishops (subject to appeal to the sovereign) have the right of excommunicating, and their sentence, if sustained, may carry civil consequences. This right is never exercised. Legally sentence of excommunication, if properly certified by the bishop, is followed by the writ *de excommunicato capiendo* for the arrest of the offender. The statute 5 Eliz. c. 23 provided for the better execution of this writ. 53 George III. greatly limited the magisterial powers.

In the Churches which consciously reshaped their policy at the Reformation the principle of excommunication is preserved in the practice of Church discipline. Calvin devoted a chapter in the *Institutes* (bk. iv. cap. xii.) to the "Discipline of the church: its principal use in Censure and Excommunication." The ends of discipline are stated to be (1) that those who lead scandalous lives may not, to the dishonour of God, be numbered among Christians, seeing that the Church is the body of Christ; (2) that the good may not be corrupted by constant association with the wicked; (3) that those who are censured or excommunicated may be led to repentance. He differentiates decisively between excommunication and anathema. Anathema devotes the offending person to eternal perdition; whereas excommunication censures and punishes his conduct. Yet by warning him of his future condemnation it recalls him to salvation (*Inst.* bk. iv. chap. xii. 10). The Reformed Churches in England and America accepted the distinction between public and private offences. The usual provision is that private offences are to be dealt with according to the rule in Matt. v. 23–24, xvii. 15–17. Public offences are to be dealt with according to the rule in 1 Cor. v. 3–5.13. The public expulsion or suspension of the offender is necessary for the good repute of the Church, and its influence over the faithful members. The expelled member may be readmitted on showing the fruits of repentance.

A recent statement of Scottish (Presbyterian) practice, drawn up for parliamentary purposes in 1927, is as follows: The censures of the Church are admonition, rebuke, suspension, deposition from office and excommunication, and they are administered only on confession or proof of sin or offence. Private admonition, which is not a censure, may in certain cases meet the ends of discipline.

The question whether the power of excommunication rests in the church or in the clergy has been important in the history of English and American Reformed Churches. The general tendency has been to make it a matter for the church or congregation rather than the clergy (*see* Hooker, *Survey,* pt. 3, pp. 33–46). Hooker expressly denies the power of Synods to excommunicate, "that there should be Synods which have *potestatem juridicam* is nowhere proved in Scripture because it is not a truth" (*Survey,* bk. iv. pp. 48–49).

The Confession of faith issued in 1596 by the London-Amsterdam church, one of the original Pilgrim Fathers' churches declares that the Christian congregation having power to elect its minister has also power to excommunicate him if the case so require (Walker, *Creeds and Platforms of Congregationalism,* p. 66). In 1603 the document known as "Points of Difference" (*i.e.,* from Anglicanism) submitted to James I. sets forth "that all particular churches ought to be so constituted as having their owne peculiar officers, the whole body of every church may meet together in one place, and jointly performe their duties to God and one towards another. And that the censures of admonition and excommunication be in due manner executed for sinne, convicted, and obstinately stood in. This power also to be in the body of the church whereof the partyes so offending and persisting are members." The *Cambridge Platform* of 1648 follows in the main the line of Hooker and Calvin but expressly excepts civil rights from the operation of the sentences. The excommunicant may still "hear the word"; he is admonished as a brother, not accounted as an enemy. The Savoy Declaration of 1658 defines the theory and practice of the older English Nonconformist churches in the section on the "Institution of Churches and the order appointed in them by Jesus Christ" (xix).

In contemporary English Free Churches purity of fellowship in church is commonly secured by the removal of persons unsuitable for membership from the church books by a vote of the responsible authority. (D. M.)

EXCRETION is the elimination from the body of the waste products which would otherwise accumulate within it, and, in the case of many of these substances, would poison it. These substances come from many sources. Some are formed in the process of digestion, and are absorbed from the alimentary canal into the blood, changed to some extent by the liver but never built into the tissue. Other waste products are produced by the breakdown of body tissue, muscle, nervous tissue, glandular tissue, blood pigments and the like. To this latter class of waste products the term *endogenous* has been applied, to the former the term *exogenous.*

Paths of Excretion.—The principal paths of excretion are (1) the skin; (2) the lungs; (3) the bowel; (4) the kidneys.

1. **The Skin.**—The skin was probably the most primitive form of excretory organ. In forms of life which have no blood system, waste material is shed from the skin or from cells derived from it. In man there are two fluids excreted by the skin, namely, sweat (or perspiration) and sebum—the oily excrement of the glands attached to the hair roots.

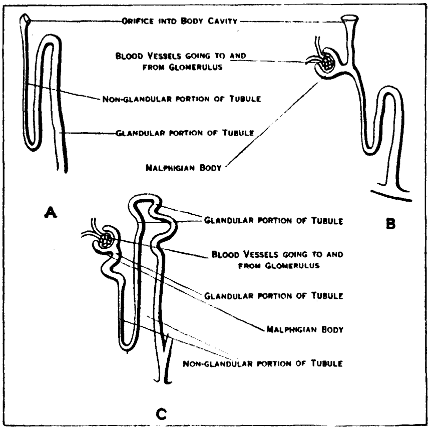
Sweat is credited with being composed of about 99% water, ·5% sodium chloride and traces of organic material of which urea is the principal. About 700 cu.cm. of water leave the skin per day in ordinary weather. Some of this is insensible evaporation from the surface of the cells rather than definite sweat secreted by the sweat glands. But taking it all as sweat—not more than 3·5 grams of urea per day (and probably much less) could be accounted for as cutaneous secretion—about one tenth of the amount secreted by the kidneys.

Nevertheless this potentiality of the skin to serve as an excretory organ can be turned to account in cases of kidney disease in order to relieve the kidney. Thus residence in Egypt or some place of similar climate attains this end.

The secretion of sweat, apparently unlike that of urine, is under the direct ordering of the central nervous system (*see* SYMPATHETIC SYSTEM). Many foreign substances such as guanine, iodine, arsenic, mercury and certain organic acids are capable of being excreted from the body in the sweat. The main function of the perspiration is however concerned with the regulation of temperature (*see* ANIMAL HEAT).

2. **The Lungs.**—Next to carbonic acid, water is the most important substance secreted by the lungs. The amount of water lost to the body through the respiratory system depends simply

on the amount of air passed into and out of the respiratory passage. Each litre of air inhaled, in ordinary temperate climates acquires about 50 milligrams of water. Something in the region of 500 cc. of water per day leaves the body in the breath if respiration is quiet. When active exercise is taken the amount of water evaporated in the lung rises *pari passu* with the total ventilation and it is possible that in a contest such as the University Boat-race



SCHEMATIC DIAGRAM OF (A) NEPHRIDIAS TUBULE OF EARTH-WORM, (B) TUBULE OF EMBRYONIC DOG-FISH, (C) TUBULE OF HUMAN KIDNEY

lasting about 20 minutes, 50 grams of water might be evacuated in the breath of each oarsman. Any easily vapourizable substance which may be present in the blood, is liable to be eliminated to some extent through the lungs, such as ether or chloroform; alcohol if drunk or acetone if produced as the result of abnormal metabolic processes as in diabetes. Hydrogen sulphide gas, if introduced into the intestine is exhaled in a short time in the breath.

3. **The Bowel.**—The stools contain such residue of the food as has escaped digestion, but to this are added other substances which give the matter eliminated from the bowel more definitely the character of a *bona fide* excretion.

The liver pours bile into the intestine, this fluid containing among its constituents bile salts, bile pigments, lecithin and cholestrin. Bile-pigments (bilirubin and biliverdin) represent the breakdown of the haemoglobin of the blood. They consist substantially of the haemoglobin minus the globin and the iron. Factors which increase the breakdown of blood will therefore increase the quantity of bile pigment eliminated. In the intestine, these pigments undergo reduction so that the actual yellowish colour of the faeces is due to the reduced product stercobilin. If the normal path of excretion of bile pigment be interfered with bilirubin becomes deposited in the skin, the condition being that of jaundice.

Certain metals, iron and possibly calcium appear to be excreted through the bowel and of course in abnormal cases water in large quantities may be so excreted.

Much of the solid portion of the faecal matter consists not of the residues of food but of actual material produced in the bowel—the dead bodies of bacteria, the residue of cells which have been shed by the mucosa and so forth. This fact perhaps accounts for the large amount of purine bodies found in the faeces as compared with the urine.

4. **The Kidneys.**—By far the most important organs of excretion are the kidneys and on them principally falls the burden of preserving the constancy of composition of the blood. They are always secreting, though not always at the same rate. The fluid secreted is driven down the ureters to the bladder in which it accumulates until such time as micturation takes place. The composition of urine naturally varies greatly from time to time, because the object of the kidney is *not* to produce so much urine of such and such a composition per day, but to leave the blood at the end of the day in the same condition as that in which it found it twenty-four hours previously.

Taking, however, the example of a person not engaged in active employment and on a standard diet—such for instance as an accident case in hospital—the composition of the urine secreted in 24 hours would be somewhat as follows:

TABLE I. *Composition of 24 Hours' Secretion of Urine*

Water	1,500 cu. cm.		Chlorine	10	grams
Solids	60	grams	Phosphoric acid	2·5	,,
Urea	33	,,	Sulphuric acid	2·5	,,

In examining the particulars given it will be observed that the kidney does not merely abstract certain substances such as urea, which are present only in small quantities in the blood, but it refrains from abstracting other substances such as protein and sugar which though present in considerable quantities in the blood are absent or nearly so from normal urine.

Of the materials enumerated in table 1 two only are known to be produced in the kidney itself, hippuric acid and ammonia salts. The other nitrogenous bodies are brought to the kidney in the blood.

Urea is by far the most important nitrogenous constituent of normal urine. It is made in the liver from amino bodies or ammonium salts and represents the final breakdown of protein, whether of the food or of the tissues. Normally more than half the urea is formed directly from the breakdown of proteins in food. In birds there is little urea, the principal nitrogenous excrement being uric acid. This gives the avian droppings their white solid nature.

Uric acid in mammals represents only the waste products of the nuclei of cells.

Creatinine is probably the constituent in the daily output which is most constant in amount, being 1–2 grams per day and is believed to be entirely of endogenous origin though the precise substances from which it is formed are by no means certain.

The Work Done by the Kidney.—Any process by which a solution of a certain saline concentration is converted into two other solutions each of different saline concentration from the original involves the absorption of energy in whatever apparatus—living or dead—the transformation is carried out. No mere filter could ever transform plasma into urine, though even in a filter some source of energy must be postulated to supply a head of pressure necessary to drive the materials through the filter.

The actual process of urinary excretion consists of an act by which urine is derived from blood plasma. The average composition of the two may be compared. The following are some of the more bulky constituents of each, expressed in percentages:—

Constituent	Blood plasma	Urine
Water	91–93	97
Protein	8	Nil
Urea	·02–·05	2·2
Sugar	·1–·15	Nil
Sodium chloride	0·9	1·2
Phosphate	·002	·17

For any one component the actual work is calculated in the following formula. If W be the work in calories: T the absolute temperature: C the molecular concentration of the substance in the arterial blood and C′ that in the urine and V the volume of urine secreted in litres—

$$W = 2VT\left(C'\log\frac{C'}{C} - (C'-C)\right)$$

Take for instance the case of urea secretion per day. V = 1·5 litres: T = 310° absolute: C = ·004 gram molecules per litre (·024%): C′ = 4 gram molecules per litre (2·4%)

$$W = 2 \times 1\cdot 5 \times 310 \left[\cdot 4 \log_e \frac{\cdot 4}{\cdot 004} - (\cdot 4 - \cdot 004) \right] = 1{,}344 \text{ calories}$$

As the efficiency of the kidney is not likely to be less than that of other organs, which means that at least three times as much energy must be expended by the organ as is actually represented by work accomplished, therefore the expenditure of energy in secreting this one constituent of the urine is about 4,000 calories which represents about ·15 of the total energy of the food eaten per day.

Functioning of the Kidney.—Few questions have intrigued physiologists more than the enquiry into the means by which the kidney works the transformation from plasma to urine. In the ultimate sense we do not know how the miracle is performed any more than we know how living matter carries out any of the other manifestations of its vitality. Between ultimate knowledge and complete ignorance there is, however, a wide territory, much of which has been explored and some of which has been mapped out with certainty.

One of the simplest forms of kidney is that of the earth-worm, though possibly the word "kidney" is scarcely applicable here, inasmuch as the multitudinous tubules of which the renal apparatus is composed are not bound up into a single organ but exist separately—a pair being situated in each typical segment of the worm. Each tubule is distinct from its neighbours. The tubule is open at each end, one orifice leads from the interior of the body cavity of the worm, the other to the outer air. The body cavity of the worm contains fluid; this fluid passes in greater or less quantities down the tubule. Its passage is promoted by the movement of the ciliary coat which lines the tubule. But that is not all: the tubule, which is a much coiled affair, is not uniform either in calibre or in the structure of its walls. In certain parts the so-called "glandular" portions, the tubule is of greater diameter than elsewhere, the wall is thicker and the cells of which the wall is composed, are made of granular protoplasm—protoplasm of the type which we are accustomed to associate with glandular secretion. These portions of the tubule also are well supplied with blood vessels, and it is clear that in some way there is an exchange of material between the blood and the fluid passing down the tubule. But what is the nature of this exchange? Is material transferred from the tubule fluid to the blood; or is it transferred from the blood to the interior of the tubule; or do both operations take place? Does the cell of the tubule say in effect, "Here is all this body fluid running to waste; let me reclaim such of its water and other constituents as may be useful to the body and restore them to the blood"? Or does it say, "Here is a water-course running to the exterior; let me pick out such things from the blood as are superfluous and cast them into this channel"? Or can the tubule perform both these functions? These are questions difficult to answer, but they are among those asked concerning all the higher forms of kidney.

Passing to the vertebrates, the kidney of the embryonic dog-fish is not entirely unlike the excretory system of the worm. It, too, consists of a series of tubes, passing down a portion of the body. A typical tube in this embryo opens by a funnel into the body cavity; the other end of this tube does not, like that of the worm, open directly into the external air, but into a longitudinal duct which gathers up all the urine from all the tubules on its side of the body. Something new, however, appears on the tubule of the dogfish: a sort of hollow shaped expansion or cup grows out in one place. Into the cavity of the cup grows a knot of blood vessels called the glomerulus. The cup is called the Malpighian Body. Such primitive tubules may develop into sperm ducts or kidney tubules; in the latter case the opening into the body cavity becomes closed. There remains, therefore, a series of closed tubules which form the kidney, each of which has two contacts with the blood (1) along the general length of the tubule, this being surrounded with capillaries and (2) at the Malpighian Bodies, one or more of which occurs on each tubule.

The Human Kidney.—The human kidney consists of a mass of tubules, each coiled into an S shape, each terminating at one end with a Malpighian Body, and each making, therefore, two contacts with the blood, one along the length of the tubule and one with the glomerular tuft of capillaries in the Malpighian Body. The actual expansion of the tubule surrounding the glomerulus is called the capsule of Bowman, the capsule of Bowman and the glomerulus together forming the Malpighian Body.

The same question arises with regard to the function of the human kidney as in the case of the kidney of the earth-worm. Does this tubule cell abstract material from within the tubule and transfer it to the blood, thus saving it for the organism? Or does the tubule cell select material from the blood and transfer it to the tubule? Or do both processes occur?

But in addition there is another question not met with in the tubule of the worm—what is the function of the glomerulus? Physiologists would agree that in a sense the function of the glomerulus has much in common with that of the funnel of the earth-worm; that is to say, the glomerulus is the source of the stream of fluid which passes down the tubule. As, however, this fluid is derived from the blood and not from the coelom, a series of open tubes would allow the animal to bleed to death. Some permeable filter must be placed between the blood vessel and the tubule; and such a filter is the combined capillary wall and surface of the Bowman's capsule. Through this filter, so far as is known, neither red blood corpuscles nor plasma proteins normally pass.

As to precisely what other materials pass through the glomerular filter there is no real agreement. Some authorities believe that all the constituents of plasma, other than their proteins are so filtered and that the urine attains its ultimate composition by the reclamation of some of the constituents as the fluid passes down the tubule. If this theory is correct, all the sugar which filters into the cavity of the Bowman's capsule would have to be either reabsorbed or oxidised in the tubular passage, for the urine is normally free from sugar. Moreover, since the concentration of urea in urine is seventy (or more) times that in plasma, it follows that if no urea is added to the urine in its way down the tubule, seventy times as much water must be filtered through the glomerulus as appears in the urine, *i.e.*, about 100 litres per day.

At the other end of the scale is the view that only water and certain crystalline bodies such as salt pass into the tubules, through the glomerulus but that the remainder, including the nitrogenous bodies, the phosphates, the sulphates, etc., leave the blood vessels which surround the tubules and are secreted into the fluid which is passing down the tubules. On this theory both the functions of the glomerulus and of the tubules would be acts of secretion involving the transformation of potential energy stored in the cells. Between the two views put forward there are many grades of opinion. Thus it is quite possible to believe that the glomerulus is simply a filter and the tubule an apparatus which is capable both of secretion and reabsorption. If such a view seems somewhat more complicated than either of the two extreme views, it must be borne in mind that the histology of the renal tubule is also very complicated and it seems probable that different histological units should have different functions.

It is a matter of common experience that much more urine is secreted at some times than at others. Exposure to cold, for instance, causes increased flow (*diuresis*). The cause of such changes is to be sought frequently in the regulation of the blood supply to the kidney. So far as may be judged from observation of the frog's kidney, only a fraction of the whole number of renal tubules are in use; the remainder are usually out of action because blood is withheld from them. When the skin is cold the blood flow through it becomes reduced and by way of compensation the kidney vessels open out, increasing probably not only the amount of urine which passes down each tubule but also the whole number of tubules in action. Some articles of diet, tea, coffee, etc., increase the flow of urine. This is in part simply due to the amount of water which they contain, but in part to chemical ingredients which stimulate them, *e.g.*, theobromine, caffeine, etc., such as are known as *diuretics*.

While some diuretics may act directly on the kidney-cells, others undoubtedly act on the renal vessels, in either case promoting the flow of urine.

Among the paradoxes presented by the kidney there is none

greater than its relation to the central nervous system. Apparently the cells of the kidney are not themselves directly supplied with nerves, yet their activity responds with great delicacy to the emotions, shock producing suppression of urine, while fear or excitement causes untoward production. Here also there is little doubt that in the regulation of the blood-flow is to be found the key to this paradox.

EX DIVIDEND. When the price of a stock or share is quoted "ex dividend" it means that the price does not include the dividend which has just been paid or is just about to be paid on it. It often happens that after a seller has sold a security he finds that a dividend received by him is demanded by the buyer because the security was sold ex dividend. This happens because the transfer of the security, although legally signed and stamped, did not reach the company's office in time for the formal transfer to be made in the shareholders' list before the books were closed to enable the dividend warrants to be prepared; obviously they could only be prepared by definitely closing the books for the purpose. The rules under which a security becomes ex dividend should, therefore, be thoroughly understood, and they will be found set out in the article entitled CUM-DIVIDEND; EX DIVIDEND.

EXECUTION: *see* PRACTICE AND PROCEDURE.

EXECUTORS AND ADMINISTRATORS, in English law, those persons upon whom the property of a deceased person both real and personal devolves according as he has or has not left a will. An executor can only be appointed by the will of his testator and the estate of his testator vests in him from the date of the testator's death. An administrator on the other hand is appointed by the probate division of the High Court and no estate vests in him till such appointment, the title to the property being vested till then in the judge of the probate division. Since the Administration of Estates Act 1925 this is the case whether the property be personalty or realty. As to whom the court will appoint administrators and the various kinds of administrators *see* ADMINISTRATION. Apart from these two points the rights and liabilities of executors and administrators are the same, and they may be indifferently referred to as the representatives of the deceased. Before the Land Transfer Act 1897 the real estate of the deceased did not devolve upon the representative but vested directly in the devisee or the heir-at-law, but by that Act it was provided that the personal representative should also be the real representative. Under this Act legal estates in copyhold and fees tail did not vest in the deceased's personal representatives, but now copyhold tenure is abolished and by the Administration of Estates Act 1925 fees tail, whether in land or goods, vest in the owner's executors if he disposes of them by his will. As the representative stands in the shoes of the deceased he is entitled to sue upon any contract or for any debt which the deceased might have sued in his lifetime.

The Duties of a Representative are as follows:

1. To bury the deceased in a manner suitable to the estate he leaves behind him; and the expenses of such funeral take precedence of any duty or debt whatever; but extravagant expenses will not be allowed.

2. Administration (which includes probate) will now be granted to not more than four persons. A person appointed executor by the will of another cannot be compelled to act as executor unless he intermeddles with the testator's assets; but he can be called upon either to take out probate or renounce. Where administration has been improperly granted all acts done by the persons to whom it is granted in due course of administration before the grant is revoked are valid.

3. Strictly speaking he should compile an inventory of all the estate of the deceased, whether in possession or outstanding, and he is to deliver it into court on oath. He is to collect all the assets so inventoried and in his discretion to commence actions to get in all those outstanding. It is necessary to file an affidavit setting out the value of the estate of the deceased upon applying for a grant of probate or letters of administration. The representative must pay the debts of the deceased to the extent of the assets real and personal which he has received or which he might have received but for his own wilful default. Realty and personalty are now equally liable for the payment of the deceased's debts. Formerly intricate rules as to the priority of payment of debts applied at least to personal assets. These rules are not expressly abolished where the estate is solvent, but there they are of no importance. Where the estate is insolvent the deceased's debts of all kinds are payable according to the rules applicable in bankruptcy whether the estate is wound up by the personal representatives or by the court (Administration of Estates Act 1925; *see* also BANKRUPTCY). Though the creditors can, if necessary, take all the estate of the deceased to satisfy their claims, yet as between the various classes of assets the representative must pay the debts out of assets in the following order: (i.) Property not disposed of by will; (ii.) property disposed of by a residuary gift; (iii.) property specifically appropriated by the will for the payment of debts; (iv.) property charged with and left subject to the payment of debts; (v.) general legacies; (vi.) specific legacies and devices; (vii.) property over which the will exercises a general power of appointment and fees tail of which the testator was life tenant and which he disposes of by will.

4. The debts of the deceased being satisfied, the representative must next proceed to satisfy the legacies and devises left by the testator. In order to enable him to do this with safety to himself, it is provided that he cannot be compelled to divide the estate among the legatees or next of kin until 12 months from the death of the deceased (this is commonly known as "the executor's year"), though if there is no doubt as to the solvency of the estate he may do so at once. As a further protection the representative may give notice by advertisement for creditors to send in their claims against the estate, and on expiration of the notices he may proceed to divide the estate, though even then the creditor may follow the assets to the person who has received them and recover for his debt. As between legatees the following priorities must be observed: (1) Specific legatees and devisees, (2) demonstrative legatees and (3) general legatees. Formerly real estate was not liable for the payment of general legacies. Now all the testator's property is treated as a single fund and general legacies are payable out of it without any charge.

5. The residue, after all the legacies and devises are satisfied, must, if there be a will, be paid to the residuary beneficiary therein named, and if there be no will it is divisible among the statutory next of kin. (*See* INTESTACY.) It was held at one time that in default of a residuary legatee the residue fell to the executor himself, but now nothing less than the expressed intention of the testator can give it to him.

The liabilities of the representative may be shortly stated. He is liable in his representative capacity in all cases where the deceased would be liable were he alive. To this general rule there are some exceptions. The representative cannot be sued for breach of contract for personal services which could be performed only in the lifetime of the person contracting, nor again can he be sued in a case where unliquidated damages only could have been recovered against the deceased. He is liable in his personal capacity in the following cases: if he contracts in writing to pay a debt due by the deceased, or if having admitted that he had assets in his hands sufficient to pay a debt or legacy he has misapplied such assets so that he cannot satisfy them; or lastly, if by mismanaging the estate and effects of the deceased he has made himself liable for a *devastavit.* Shortly stated, a representative is bound to exercise the ordinary care of a business man in administering the estate of the deceased, and he will be liable for the loss to the estate caused by his own negligence, or by the negligence of a co-representative which his act or neglect has rendered possible. Though the general rule of *delegatus non potest delegari* holds

good of a representative, yet in certain cases he may "rely upon skilled persons in matters in which he cannot be expected to be experienced," *e.g.*, he must employ solicitors to conduct a lawsuit.

The privileges of the representative are these: he may prefer one creditor to another of equal degree; he may retain a debt owing to him from the deceased as against other creditors of equal degree (*see* RETAINER); he may reimburse himself out of the estate all expenses properly incurred in the execution of his trust.

An executor *de son tort* is one who, without any title to do so, wrongfully intermeddles with the assets of the deceased, dealing with them in such a way as to hold himself out as executor. In such a case he is subject to all the liabilities of an executor, and can claim none of the privileges though recent legislation seems to have conferred upon him the right to retain. He may be treated by the creditor as the executor, and, if he is really assuming to act as executor, creditors and legatees will get a good title from him, but he is liable to be sued by the rightful representative for damages for interfering with the property of the deceased.

Scotland.—Executor in Scots law is a more extensive term than in English. He is either nominative or dative, the latter appointed by the court and corresponding in most respects to the English administrator. Caution is required from the latter, not from the former. By the common law doctrine of passive representation the heir or executor was liable to be sued for implement of the deceased's obligations. The Roman principle of *beneficium inventarii* was first introduced by an Act of 1695. As the law at present stands, the heir or executor is liable only to the value of the succession, except where there has been vitious intromission in movables, and in *gestio pro haerede* (behaviour as heir) and other cases in heritables. The present inventory duty on succession to movables and heritables depends on the Finance Acts 1894–1909. (*See* ESTATE DUTY.) All debts are payable *pari passu* except privileged debts. (*See* PRIVILEGE.) (J. A. ST.; X.)

UNITED STATES

In the great majority of the States of North America, special courts have been established by statute and invested with jurisdiction over the administration of the estates of deceased persons. These courts are commonly denominated as probate, orphans' or surrogate courts. The court of the county in which the deceased was resident at the time of his death is primarily entrusted with the duty of administration. It is the law of that State which will govern the devolution of his property. Other States in which the deceased may have had assets will order their distribution according to the law of the deceased's domicile. The executor or administrator, however, is only an officer of the court which confirms his appointment, and letters testamentary or of administration have no legal effect outside the territorial limits of the State in which they were granted. Consequently, ancillary administration must be secured in order to collect assets of the estate in any jurisdiction in which the deceased was not a resident. Statutes provide for the ready appointment of ancillary administrators and often give preference in this respect to the domiciliary executor or administrator. Without such authority the domiciliary executor or administrator, though invested with title to the assets in the foreign State, has no right to remove them nor can he sue upon outstanding claims due to the deceased in order to reduce them to possession.

The fact of death and the deceased's residence within the county are essential to the validity of a grant of letters testamentary or of administration. Statutes make provision for administration of estates of persons who have disappeared for such a length of time as would lead to a presumption of their death. In the United States, contrary to the common law doctrine, an executor is not entitled to exercise his powers before the probate of the will and the grant of letters testamentary, though until that time he may perform such acts as may be necessary to preserve the estate. Statutes also provide for revocation of powers granted to an executor upon proof of fraud or mismanagement in the conduct of his duties.

The executor's duty, broadly speaking, is to wind up the business of the deceased and distribute the assets. He has no power, except under extraordinary circumstances or by leave of the probate court, to carry on the business or change the character of the deceased's investments. He must file an inventory of the deceased's assets within a period commonly prescribed as between three and six months. Statutes impose upon him a duty to give notice to creditors of the deceased to present their claims. Failure to present claims within a stipulated time operates to bar them. The deceased's estate is liable upon all contract claims except those where death operates as an excuse for non-performance. Statutes have generally changed the common law rule absolving the estate from liability for torts committed by the deceased during his lifetime. Obligations incurred by the executor in behalf of the estate after the death of the testator impose a liability upon the executor and not upon the estate, though in proper cases he can demand reimbursement from the estate. The executor must render an account to the probate court of his administration of the estate. Statutes usually provide that a final settlement cannot be demanded of the executor until the expiration of a year or 18 months.

At common law realty descended to the heirs and could not be sold by the executor for the payment of the deceased's debts unless the deceased had specified to the contrary. In most States to-day, though the realty still descends to the heirs, the executor or administrator is authorized to apply to the court and obtain leave to sell real estate in order to pay debts. Such legislation may make the realty equally liable with the personalty for the payment of debts or provide that the personalty must first be exhausted before recourse may be had against the realty. So much of the realty as consists of homestead rights is exempted from this liability and preserved for the benefit of the widow or children. Where the estate is insolvent the problem as to what debts should first be satisfied and what preferences may be made by the executor as between competing creditors is now governed by legislation which has abrogated much of the ancient common law doctrine. The order in which legacies are to be paid, however, generally follows the common law principles.

The executor's compensation is usually governed by statutes allowing a certain percentage upon the value of the estate. In the absence of statute he is entitled to a reasonable allowance which is determined by the probate court.

American jurisdictions have been unfriendly to the common law doctrine of executors *de son tort*. Some States have expressly abolished the institution; the courts of other States by regarding the extensive statutory regulation of executors and administrators as a completed system that superseded common law doctrines have treated such legislation as impliedly abolishing the office of executor *de son tort*. Still other States by judicial decision have narrowed the broad liabilities imposed upon him at common law. (J. M. LA.)

EXEDRA, a term originally describing any outdoor seat or recess. Because such seats were usually semicircular, in modern architectural usage the term has come to signify any semicircular seat or recess, however large, indoors or out. In the Roman baths they were of large size and like apses were covered with a hemispherical vault. An example exists at Pompeii in the Street of the Tombs. From Vitruvius we learn that they were often covered over, and they are described by him as places leading out of porticoes, where philosophers and rhetoricians could debate or harangue. The term is differentiated from apse (*q.v.*) by the fact that an apse is usually at the end of an aisle or building, and designed to enshrine an altar, tomb or statue, whereas an exedra may be in any location and without such definite purpose.

EXELMANS, RENÉ JOSEPH ISIDORE, COUNT (1775–1852), marshal of France, was born at Bar-le-Duc on Nov. 13, 1775. He volunteered into the 3rd battalion of the Meuse in 1791, and served almost continuously through the Revolutionary Wars. He became a lieutenant in 1797, and in 1798 was aide-de-camp to General Éblé, and in the following year to General Broussier. In his first campaign in Italy he greatly distinguished himself, and in April 1799 he was rewarded for his services by the grade of

captain of dragoons. In the same year he took part with honour in the conquest of Naples and was again promoted. In 1801 he became aide-de-camp to Murat, whom he accompanied in the Austrian and Polish campaigns of 1805, 1806 and 1807. At the passage of the Danube, and in the action of Wertingen, he specially distinguished himself; he was made colonel for the valour which he displayed at Austerlitz, and general of brigade for his conduct at Eylau in 1807. In 1808 he accompanied Murat to Spain, but was there made prisoner and conveyed to England. On regaining his liberty in 1811 he became grand-master of horse to Murat at Naples, but rejoined the French army just before the Russian campaign. He was promoted general on the field of Borodino. In the retreat from Moscow his steadfast courage was conspicuous. In 1813 he was made, for services in the campaign of Saxony and Silesia, grand-officer of the Legion of Honour, and in 1814 he reaped additional glory by his intrepidity and skill in the campaign in France. When the Bourbons were restored Exelmans retained his position in the army. Napoleon after his return from Elba made Exelmans a peer of France and placed him in command of the II. Cavalry Corps which he led in the Waterloo campaign, the battle of Ligny and Grouchy's march on Wavre. In the closing operations around Paris he won great distinction. After the second restoration he denounced, in the House of Peers, the execution of Marshal Ney as an "abominable assassination" and was thereafter compelled to live in exile until 1819. In 1828 he became inspector-general of cavalry, and in 1851 a marshal of France. He died on July 10, 1852.

EXEQUATUR, the letter patent, issued by a foreign office and signed by a sovereign, which guarantees to a foreign consul the rights and privileges of his office, and ensures his recognition in the State in which he is appointed to exercise them. If a consul is not appointed by commission he receives no exequatur; and a notice in the *Gazette* in this case has to suffice. "Exequatur" is also used, in some countries of Europe, of the order made by a court authorizing the enforcement of a foreign judgment.

EXETER, EARL, MARQUESS AND DUKE OF. These English titles have been borne at different times by members of the families of Holand or Holland, Beaufort, Courtenay and Cecil. The earls of Devon of the family of de Redvers were sometimes called earls of Exeter; but the 1st duke of Exeter was JOHN (*c.* 1355–1400), a younger son of Thomas Holand, earl of Kent (d. 1360). He owed his high station at the English court to the fact that he was the king's half-brother, his mother having married Edward, the Black Prince. He married Elizabeth (d. 1426), a daughter of John of Gaunt, duke of Lancaster, and was constantly in Richard's train until 1385, when his murder of Ralph Stafford disturbed these friendly relations. In 1387 he was created earl of Huntingdon, admiral of the fleet and chamberlain of England, and was again high in the king's favour. In 1397, after assisting Richard in the proceedings against the lords appellant, he was created duke of Exeter. After the accession of his brother-in-law, Henry IV., Holand was tried for his share in the events of 1397, and was reduced to his earlier rank of earl of Huntingdon. His plots against Henry, led to his capture and execution at Pleshey, Essex, on Jan. 16, 1400[1]. He was afterwards attainted and his titles and lands were forfeited.

In 1416 THOMAS BEAUFORT, earl of Dorset, was created duke of Exeter for life. In the same year JOHN (1395–1447), son of John Holand, the former duke of Exeter, was allowed to take his father's earldom of Huntingdon. This nobleman assisted Henry V. in his conquest of France, fighting both on sea and on land. He was marshal of England, admiral of England and governor of Aquitaine under Henry VI.; was one of the king's representatives at the conference of Arras in 1435; and in 1443 was created duke of Exeter. When he died on Aug. 5, 1447, his titles passed to his son HENRY (1430–1473), who, although married to Anne (d. 1476), daughter of Richard, duke of York, fought for Henry VI. during the Wars of the Roses. After having been imprisoned by York at Pontefract, he was present at the battle of Towton, sailed with Henry's queen, Margaret of Anjou, to Flanders in 1463, and was wounded at Barnet in 1471. In 1461 he had been attainted and his dukedom declared forfeited, and he died without sons, probably in 1473.

Coming to the family of Courtenay the title of marquess of Exeter was borne by HENRY COURTENAY (*c.* 1496–1538), earl of Devon, who was made a marquess in 1525. Courtenay was a prominent figure at the court of Henry VIII. until Thomas Cromwell rose to power, when his high birth, his great wealth and his independent position made him an object of suspicion. Some slight discontent in the west of England gave the occasion for his arrest, and he was tried and beheaded on Dec. 9, 1538. A few days later he was declared a traitor and his titles were forfeited; although his only son, EDWARD (*c.* 1526–1556), who was restored to the earldom of Devon in 1553 and was a suitor for the hand of Queen Mary, is sometimes called marquess of Exeter.

The title of earl of Exeter was first bestowed upon the Cecils (*see* CECIL: *Family*) in 1605 when THOMAS, 2nd Lord Burghley (1542–1623), the eldest son of William Cecil, Lord Burghley, was made earl of Exeter by James I. Thomas was a member of parliament during the reign of Queen Elizabeth, who knighted him in 1575, and had fought under the earl of Leicester in the Netherlands. In 1598 he became president of the Council of the North and was made a knight of the Garter. He died on Feb. 7, or 8, 1623. His direct descendants continued to bear the title of earl of Exeter, and in 1801 HENRY (1754–1804), the 10th earl, was advanced to the dignity of marquess of Exeter, the present marquess being his lineal descendant. The 1st marquess is Tennyson's "lord of Burghley."

See G. E. C(okayne), *Complete Peerage* (1887–98).

EXETER, a city and county of a city, municipal borough, and the county town of Devonshire, England, 172 m. W.S.W. of London, on the S.R. and the G.W.R. Pop. (1921) 59,582.

History.—Exeter was the Romano-British country town of *Isca Damnoniorum*. Mosaic pavements, potsherds, coins and other relics have been found, and probably traces of the Roman walls survive. It is said to be the *Caer Isce* of the Britons, and its importance as a British stronghold is shown by the great earthwork which the Britons threw up to defend it, on the site of which the castle was afterwards built, and by the number of roads which branch from it. Exeter is famous for the number of sieges which it sustained as the chief town in the south-west of England. In 1001 it was unsuccessfully besieged by the Danes, but in the following year was given by King Aethelred to Queen Emma, who appointed as reeve, Hugh, a Frenchman, owing to whose treachery it was taken and destroyed by Sweyn in 1003. By 1050, however, it had recovered, and was chosen by Leofric as the new seat of the bishops of Devon. In 1068, after a siege of 18 days, Exeter surrendered to the Conqueror, who threw up a castle which was called Rougemont, from the colour of the rock on which it stood. Again in 1137 the town was held for Matilda by Baldwin de Redvers for three months and surrendered, at last, owing to lack of water. Three times subsequently Exeter held out successfully for the king—in 1467 against the Yorkists, in 1497 against Perkin Warbeck, and in 1549 against the men of Cornwall and Devon, who rose in defence of the old religion. During the civil wars the city declared for parliament, but was in 1643 taken by the royalists, who held it until 1646. The only other historical event of importance is the entry of William, prince of Orange, in 1688, shortly after his arrival in England. Exeter was a borough by prescription some time before the Conquest, since the burgesses are mentioned in the Domesday Survey. Its first charter granted by Henry I. gave the burgesses all the free customs which the citizens of London enjoyed, and was confirmed and enlarged by most of the succeeding kings. By 1227 government by a reeve had given place to that by a mayor and four bailiffs, which continued until the Municipal Reform act of 1835. Numerous trade gilds were incorporated in Exeter, one of the first being the tailors' gild, incorporated in 1466. This by 1482 had become so powerful that it interfered with the government of the town, and was dissolved on the petition of

[1]There is some difference of opinion about the place and manner of the earl's death, and this question has an important bearing upon the privilege of trial by peers of the realm. *See* L. W. Vernon-Harcourt, *His Grace the Steward and Trial of Peers* (1907).

the burgesses. Another powerful gild was that of the merchant adventurers, incorporated in 1559, which is said to have dictated laws to which the mayor and bailiffs submitted.

From 1295 to 1885 Exeter was represented in parliament by two members, but in the latter year the number of representatives was reduced to one. Exeter was formerly noted for the manufacture of woollen goods, introduced in Elizabeth's reign, and the value of its exports at one time exceeded half a million sterling yearly. The trade declined partly owing to the stringent laws of the trade gilds, and by the beginning of the 19th century had entirely disappeared, although at the time of its greatest prosperity it had been surpassed in value and importance only by that of Leeds.

Site.—The ancient city occupies a broad ridge of land, which rises steeply from the left bank of the Exe. At the head of the ridge is the castle, on the site of a great British earthwork. There is a maze of streets within the ancient walls, the line of which may be traced. All the gates have disappeared. The suburbs, which have greatly extended since the beginning of the 19th century, contain many good streets, terraces and detached villas. The lofty mound of the castle is laid out as a promenade, with trees and walks.

Cathedral and Institutions.—The cathedral is mainly of Decorated Gothic except for its Norman transeptal towers, and dates from 1280 to 1369. Transeptal towers occur elsewhere in England only in the collegiate church of Ottery St. Mary, in Devonshire, for which Exeter cathedral served as a model. The west front is of later date than the rest, and the porch is wholly covered with statues. Within, the most noteworthy features are the long unbroken roof, extending throughout nave and choir, with no central tower or lantern; the sculpture of bosses and corbels; the minstrel's gallery, projecting from the north triforium of the nave; and the manner in which the several parts of the church are made to correspond. The window tracery is much varied; but each window answers to that on the opposite side of nave or choir; pier answers to pier, aisle to aisle, and chapel to chapel, while the transeptal towers complete the balance of parts. A complete restoration under Sir G. G. Scott was carried out between 1870 and 1877. The episcopal throne, a sheaf of tabernacle work in wood, was erected by Bishop Stapeldon about 1320, and in the north transept is an ancient clock and a bell weighing 2,500 lbs. Some important mss., including the famous book of Saxon poetry given by Leofric to his cathedral, are preserved in the chapter-house. The united sees of Devonshire and Cornwall were fixed at Exeter from the installation there of Leofric (1050) by the Confessor, until the re-erection of the Cornish see in 1876. The bishop's palace embodies Early English portions. The diocese covers the greater part of Devonshire, with a very small part of Dorsetshire.

The guildhall in the High Street is an Elizabethan building, and contains some portraits by Sir Peter Lely. The assize hall and sessions house dates from 1774. There is a good collection of local birds, and some remarkable pottery and bronze relics extracted from barrows near Honiton or found in various parts of Devonshire in the Albert Memorial Museum. Of the castle, called Rougemont, a portion of a gateway tower which may be late Norman, remains. Traces are also seen of the surrounding earthworks, which may have belonged to the original British stronghold. The Devon and Exeter Institution, founded in 1813, contains a large and valuable library. The Grammar school was founded by Walter de Stapeldon, bishop of Exeter and founder of Exeter College, Oxford, in 1332, and refounded in 1629, but occupies modern buildings outside the city. There are two market-houses in the city, and many institutions, including the hospital or almshouse of William Wynard, recorder of Exeter (1439).

Commerce.—Exeter is one of the principal railway centres in the south-west, and it also has some shipping trade, communicating with the sea by way of the Exeter ship-canal, originally cut in the reign of Elizabeth (1564), and enlarged in 1675 and 1827. This is the first canal carried out in the United Kingdom for the purpose of enabling sea-going vessels to pass to an inland port. The river Exe was very early utilized by small craft trading to Exeter, parliament having granted powers for the improvement of the navigation by the construction of a canal 3 m. long from Exeter to the river; at a later date this canal was extended lower down to the tidal estuary of the Exe. Previous to the year 1820 it was only available for vessels of a draft not exceeding 9 ft., but by deepening it, raising the banks, and constructing new locks, vessels drawing 14 ft. of water were enabled to pass up to a basin and wharves at Exeter. These works were carried out under the advice of Thomas Telford. A floating basin is accessible to vessels of 350 tons. Larger vessels lie at Topsham, at the junction of the canal with the estuary of the Exe; while at the mouth of the estuary is the port of Exmouth. The imports are coal, oilcake, timber, slates, grain, fish, cement, manure, pig iron, etc., while ground barytes, timber, scrap iron, paper and cider are exported. Brewing, paper-making and iron-founding are carried on, and the city is an important centre of agricultural trade. The parliamentary borough returns one member. The eastern suburb of Heavitree is an urban district with a population (1921) 11,465.

EXETER, a town of south-eastern New Hampshire, U.S.A., on the Squamscott river, 12m. S.W. of Portsmouth; the county seat of Rockingham county. It is served by the Boston and Maine railroad. The population was 4,604 in 1920. It is the seat of Phillips Exeter academy, one of the foremost secondary schools of the country, founded in 1781 by Dr. John Phillips (1719–95), a Harvard graduate who acquired considerable wealth as a merchant at Exeter and gave nearly all of it to promote education. The academy numbers among its alumni Daniel Webster, Edward Everett, John Parker Hale, George Bancroft, Jared Sparks, Robert T. Lincoln and many other men of prominence. The town was founded in 1638 by the Rev. John Wheelwright, an Antinomian leader who with a number of followers settled here after he was banished from Massachusetts. For their government the settlers adopted a plantation covenant, but in 1643 the majority submitted to the jurisdiction of Massachusetts, while the minority, including the founder, moved away. In 1680 the town became a part of the new province of New Hampshire. During the French and Indian wars it was usually protected by a garrison. One of the garrison houses and some fine colonial homes are still standing. New Hampshire was the first of the colonies to adopt a constitution, and it was in Exeter, in Jan. 1776, that the first independent State government was formed. The legislature met here regularly from 1776 to 1782, and usually thereafter until 1800. Exeter was the birthplace of Lewis Cass, Henry A. Shute, Ambrose Swasey, Edward Tuck and Daniel Chester French.

EXETER BOOK (*Codex Exoniensis*), an anthology of Anglo-Saxon poetry presented to Exeter cathedral by Leofric (bishop of Exeter from 1050 to 1071), and still there. It contains legal documents, the poems entitled *Crist, Guthlac, The Wanderer,* etc., and 80 or 90 riddles. It was first described in Wanley's *Catalogus* (1705), with many inaccuracies; subsequently by Conybeare, "Account of a Saxon Manuscript" (*Archaeologia*, xvii. 180–197, 1814). A complete transcript made (1831) by Robert Chambers is in the British Museum (Addit. ms. 9,067). It was first printed in 1842 by Thorpe for the Soc. of Antiq., London. More recent editions are:—in Grein's *Bibliothek der A.S. Poesie* (vol. iii. part 1, ed. Wülker, Leipzig, 1897). Schipper in Pfeiffer's *Germania*, xix. 327–339, and Gollancz, *Exeter Book*, pt. i. (1895), with translation (E.E.T.S.).

A detailed account, with bibliographies, is given by R. Wülker, in *Grundriss . . . der A.S. Literatur*, 218–236 (Leipzig, 1885); *see* also the introduction to *The Crist of Cynewulf*, ed. Cook (Boston, U.S.A., 1900). For the poems contained in the ms. *see* also CYNEWULF and RIDDLES. For Leofric, *see* F. E. Warren, *The Leofric Missal* (1883).

EXHAUST. The exhaust steam from an engine is disposed of in various ways: (1) It escapes direct to the atmosphere, or by way of an *exhaust-head* which acts as a silencer, and also prevents condensed steam and oil from being thrown down on to adjacent buildings. In a portable engine or locomotive it creates draught to help the fire by being directed up the chimney. (2) It operates an injector (*see* INJECTOR) or a feed-water heater, as illustrated, thus assisting the boiler by so much heat already raised and avoiding strain on the plates by feeding a cold flow against

the hot surfaces. Or some other kind of heating apparatus is worked by exhaust steam, such as an air-heater for warming buildings, workshops, or drying clothes in laundries, also wheat, cloth, timber, yarn, etc. (3) In condensing engines and turbines it passes into a partial vacuum created in a condenser (*q.v.*).

Exhaust steam from a big engine, such as a colliery winder or a rolling-mill engine, is made to do further work in low-pressure turbines. As winders run intermittently the supply of exhaust steam fluctuates and a *steam accumulator,* a large boiler-like object, containing a mass of hot water, is employed to pass steam into and furnish a reserve for short carry-over periods when the winder stops.

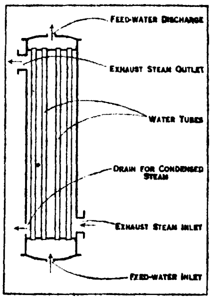

DIAGRAM OF FEED-WATER HEATER
This apparatus utilizes waste heat of exhaust steam. The steam is made to circulate round the tubes, through which the feed-water flows

Another practice which is economical of fuel is concerned with factories requiring large quantities of low-pressure heating steam for processes; these include flour-mills, paper-mills, dye-works, bleach-works, tanneries, wool-combing sheds, breweries and others. This *process steam* can be generated in low-pressure boilers, but it is cheaper to produce high-pressure steam, pass it through the engine, and take the exhaust for the process work. If the demand for heating steam is about equal to that given out by the engine, a single-cylinder *back-pressure engine* is employed, giving up all its exhaust, but with fluctuating requirements a compound cylinder *heat-extraction engine* is selected. The whole of the steam required for driving and heating passes through the high-pressure cylinder to an intermediate receiver. From this latter the desired quantity of process steam is drawn, and any excess goes in to the low-pressure cylinder and thence to the condenser.

The chief feature in respect to the exhaust from an internal-combustion engine is to let it escape as freely as possible, so as not to hamper the engine; but the necessity for silencing in so many cases renders this ideal difficult of realisation. Exhaust from large units may be led into a pit, or into a box providing for expansion of the gases, baffles or small stones assisting to break up the flow. On motor-cars baffles or perforated compartments perform a similar duty. Extra service may be obtained from an exhaust, such as to blow a whistle, or warm a car.

EXHAUSTION: *see* FATIGUE; VACUUM.

EXHIBITION AND TRADE FAIR. Although the terms "fair" and "exhibition" (or "exposition" as it is called in America) are somewhat loosely used, it may be accepted that by the latter is meant the long period show accompanied by bands, amusement park, etc., while by the former term is meant the short-period trade show. What is now known as an exhibition is of comparatively recent date, while fairs (*q.v.*) have existed from time immemorial.

The precise starting-point of the present day exhibition is not very clearly defined. There was naturally a transition period, but it may fairly be stated that the great exhibition of 1851 held in Hyde park, London, marked a definite stage in the development of the latter-day type of international or national exhibitions. Particulars of some of the more important exhibitions are given in the table on opposite page.

The Value of Exhibitions.—Considerable divergence of opinion existed and still exists as to the exact value of these great international exhibitions. Unquestionably they are of immediate gain and profit to the cities in which they are held. Vast numbers of people are attracted from all over the world to see them, with obvious benefit to those directly concerned. But the cost of participation by industrialists, especially those of the other countries, is considerable, involving the immobilization of stocks and the employment of special staffs for long periods. In those industries dependent for their prosperity on fulfilling the daily domestic needs of the bulk of the population, they are generally popular. Food, clothes, the luxury and sport trades, musical instruments and appliances of all kinds fall within this category.

The increasing frequency of exhibitions during the latter half of the 19th century, and the heavy burden which was entailed both upon the governments participating and on the individual exhibitors, pointed urgently to the need for some measure of international agreement for their limitation and control. In several important countries national committees were set up, inaugurated in 1885 by the "Comité Français des Expositions à l'Étranger," which was formed to protect the interests of French exhibitors in foreign exhibitions. The committee was so successful that in 1901 it was officially recognized (*reconnu d'utilité publique*). In 1904 a similar committee was set up in Belgium, and subsequently others were formed in Switzerland, Denmark, Germany, Italy, Austria, etc. On the invitation of the French committee, these various bodies formed themselves into an international federation for the advancement of their common interests.

In England, the task of organizing the national displays at exhibitions in which the Government participated officially had been entrusted to a body specially appointed for that purpose on each occasion, generally a royal commission. There were obvious disadvantages in this procedure, the most serious being that, owing to the complete lack of any continuity of organization, the experience gained at one exhibition was not readily available for the next.

In 1906 the British board of trade appointed a special committee to enquire into the nature and extent of the benefit accruing to British arts, industries and trade from participation in great international exhibitions. The committee found that while there was a conflict of opinion as to the direct benefit accruing, such participation could not be discontinued. It constituted an advertisement both for the individual exhibitors and for national trade in general. The chief argument in favour of participation was the necessity of keeping pace with foreign competitors. It was further remarked that political considerations were often a potent factor in determining participation.

Lack of continuous policy or system and of adequate machinery for determining the question of participation, had prevented proper preparation. The immediate result of this enquiry was the creation of a special British exhibitions department. (*See* INTERNATIONAL TRADE ASSOCIATIONS AND CONGRESSES.)

It is unfortunate that the initiative for fairs and exhibitions is often undertaken by individuals or bodies having little or no connection with the industries which such exhibitions are supposed to serve. In some instances the object is that of gain, whether direct or indirect, to the organizers or organizing localities, rather than to the exhibitors. This tendency has given rise to prejudice and suspicion, but in the case of the great international exhibitions organized under the immediate aegis of their respective governments, or enjoying the substantial and general support of all the interests involved, there can be no question of the value of their lessons. In the course of the last century they have probably had a greater influence on the development of the tastes, habits and activities of the civilized peoples than the less direct, slower process of a natural development of needs following in the train of modern scientific and mechanical progress.

Frequency of Exhibitions.—The growing tendency towards the multiplication of international exhibitions was taken up in the Convention relative to International Exhibitions, signed at Berlin on Oct. 26, 1912. The parties to the convention were the principal European powers and Japan, but not any nation of the American continent. The convention made detailed recommendations as to international exhibitions. It dealt with the recognition, patronage or authorization of such exhibitions, and the interval between universal exhibitions. (A universal exhibition is defined in the convention as one which embraces the majority of the products of human activity. It is contrasted with a "special exhibition," the scope of which is limited to one or to a few branches of human activity.) The convention was signed subject to ratification which, owing to the World War, never took place.

Place	Date	Area(acs.)	Exhibitors	Receipts	Cost	Attendance	Remarks

*Including subvention from City of Paris. **Including sale of buildings. ¶(Unofficial).
†Including cost of permanent buildings. ‡Including staffs.

The organization for the administration of exhibitions is most varied. As a general rule each project has created its own organization, and although it has had the assistance of committees of experts, sometimes of a national and permanent character, such organizations lack the benefit of past experience and continuity. The work initiated at the Berlin congress is likely to be followed up by another congress in Paris. Surely such deliberations will be able to find agreement in regulating international exhibitions and fairs in the manner most directly profitable to the interests involved. Having regard to their great cost and the strain imposed on participants, it seems likely that the universal exhibition will give place to specialized exhibitions dealing with one industry at a time. Indeed, the limitations of space in close proximity to the centres of our great capitals, the high cost of building, the increased difficulty of concentrating large numbers of people at a given spot, make such a conclusion practically imperative. It is probable, however, that exhibitions on the grand scale will continue to be held from time to time, subject to such restrictions as may be determined by international agreement, as they have come to be regarded as an appropriate form of national celebration. Examples of this are the exhibitions held at Rome and Turin in 1911 (fiftieth anniversary of the unification of Italy), at Rio de Janeiro in 1922 (centenary of Brazilian independence), at Philadelphia in 1926 (sesqui-centenary of American independence), and those announced to be held at Antwerp in 1930 (centenary of Belgian independence), and at Brussels in 1935 (centenary of Belgian railways and fiftieth anniversary of the Congo State).

The British Empire Exhibition.—Two exhibitions held since the war call for brief notice, both for their intrinsic interest and in view especially of the important influence which they have had. The first is the British empire exhibition held at Wembley park (near London) in 1924 and 1925. The exhibition was unique in its scope and purpose, inasmuch as it was confined to the products of the British empire and had as its objects the demonstration of the wealth and resources of the empire, and the promotion of inter-imperial unity. The exhibition will probably be regarded in years to come as one of the most significant events in the story of British imperial development.

Paris Exhibition, 1925.—The Exhibition of Modern Decorative and Industrial Arts held at Paris in 1925 also marked in some ways a new departure. At previous exhibitions the art exhibits—if any—had been segregated in "art palaces" (usually confined to the "fine arts"), instead of forming an integral part of the industrial exhibition. The aim of the Paris exhibition, which was abundantly fulfilled, was to secure a comprehensive display of industrial products of all kinds in which modern design plays an important part. The result was a highly interesting series of national pavilions erected by the various participating countries. The exhibits exercised an influence which can be detected in almost every form of artistic effort.

The Question of Awards.—The Paris exhibition was notable, moreover, in rehabilitating the system of awards, which had fallen somewhat into disrepute, so much so indeed that it was decided that no awards should be given at the British empire exhibition. The prestige attaching to awards given in connection with exhibitions is entirely dependent on the methods of their distribution. A well deserved award of success in industrial competition is of the highest value to the winner. Unfortunately the system of

granting awards at international exhibitions has provoked considerable criticism: whether the tendency has been towards distribution to firms rather on the basis of their commercial status and previous successes than on the intrinsic merits of their actual exhibits, or whether other less deserving considerations have been at work, the value of exhibition diplomas and medals has unquestionably depreciated. But if the methods adopted at the Paris exhibition in 1925 can be maintained, there is no reason why the system of awards should not regain its place as a true gauge of merit, with its attendant commercial value. The test of all efficiency must eventually be competition. As the high value attaching to winning an international competition, whether it be a contest in the air or on the road or track, is sufficient evidence.

TRADE FAIRS

During the World War, and to a greater extent after its close, new trade fairs sprang up all over Europe. The progress of these fairs has been remarkable. In most instances they are international, but there are a few national fairs, notably the British Industries fair in London and Birmingham and the Swiss Industries fair at Basle. They are of short duration, usually two weeks and sometimes less. In the case of the larger fairs the exhibitors run into several thousands and they are attended by buyers from all over the world. It may be that the number is excessive, but those which do not fill a need will disappear in time. The majority of fairs in Europe are held early in the spring, and in some cases an autumn fair is also organized. They generally comprise all industries except heavy machinery, and even this is sometimes shown in special halls, notably at Leipzig and Birmingham.

Apart from the general trade fairs referred to, there are a vast number of special fairs of short duration dealing with one or more industries. In this category come the great automobile shows, also shows for electrical appliances of all kinds, radiography, and all the latter-day developments of communication of speech and sound, and it is obvious that this last category will attain increased importance and dimensions. Practically every industry has its special annual demonstration and in many cases these comprise competitive sections.

The rapid post-war growth of trade fairs has also marked very clear stages in their method of development. Road-side booths or huts distributed often over large areas sometimes in a haphazard way have gradually given place to substantial permanent buildings in which trades can be arranged in their appropriate sections. This evolution on the whole has been general, but most marked perhaps in the case of Lyons and Leipzig. The system of sectional arrangement has been strictly enforced in the case of the British Industries fair since its initiation in 1915, and the convenience to buyers needs no emphasis. The question of concentration of *locale* presents far greater difficulties. Local interests, whether commercial or political, have so far prevented any approach to complete concentration in any one country. Nor does it appear probable that these conditions will disappear, but even with these disabilities it is certain that trade fairs as they at present exist have become an important and permanent factor in international commerce, and indications generally are towards development rather than diminution. The increased costs of communication and living tend to hamper the ranges of activity of the commercial traveller, and there is a growing tendency to resort to the convenient and expeditious methods of the periodic trade fair with the wide range of selection which is offered at this kind of exhibition.

The following may be noted as amongst the more important of the post-war fairs in Europe:—British Industries fair (London and Birmingham); Paris, Lyons, Lille, Bordeaux (France); Antwerp, Brussels (Belgium); Leipzig, Cologne, Frankfort, Königsberg (Germany); Basle, Lausanne (Switzerland); Milan, Padua, Naples (Italy); Valencia (Spain); Vienna (Austria); Prague, Bratislava (Czechoslovakia); Danzig; Copenhagen (Denmark); Reval (Estonia); Salonika (Greece); Budapest (Hungary); Riga (Latvia); Kaunas (Lithuania); Luxembourg; Utrecht (Holland); Bergen (Norway); Gothenburg, Malmö (Sweden); Poznan (Poland); Zagreb (Yugoslavia); Nijni Novgorod (U.S.S.R.).

One of the largest fairs in the world is the Great National exhibition held at Toronto in the early autumn, which covers an area of 350ac. and 1,500,000 sup.ft. of buildings. (*See* also FAIR.)

BIBLIOGRAPHY.—In addition to the reports and other documents issued in connection with the various exhibitions the following may be consulted:—Georges Gérault, *Les Expositions Universelles envisagées au point de vue de leurs Résultats Économiques* (1902); *Report of the Committee appointed by the Board of Trade on the Participation of Great Britain in Great International Exhibitions* (1907); *Report of His Majesty's Commissioners for the International Exhibitions at Brussels, Rome and Turin, 1910 and 1911* (1912); *Convention relative to International Exhibitions,* signed at Berlin October 26, 1912, and covering memorandum (1913); Weaver, *Exhibitions and the Arts of Display* (1925); *Reports on the Present Position and Tendencies of the Industrial Arts as indicated at the International Exhibition of Modern Decorative and Industrial Arts, Paris, 1925* (Department of Overseas Trade, 1927); Exposition Internationale des Arts Décoratifs et Industriels Modernes, Paris, 1925, *Rapport Général* (1927 *et seq.*); British Industries Fair, *Report of the Board of Trade* (1921). (H. W. G. C.)

EXHIBITION ARCHITECTURE. An exhibition or exposition is an organized display of works of industry and art, usually international in range of selection and appeal. Market, fair, mart, exhibition and exposition are terms used almost interchangeably. A fair is often a special market; and a mart has been defined as a greater species of fair. An exhibition is any general and public display, and in particular a public show of goods for the promotion of trade. By decision of an international exhibitors' conference called by the German Government in Berlin in 1912 an exhibition is universal when opened to every possible expression of human effort; it is official when it is originated directly by a Government; and it is under official patronage when it is originated by a non-Governmental body with the patronage of a Government. Generally, an exhibition or exposition is assumed to reflect human progress, to be open to every branch of human effort and to have a didactic import. A fair may be assumed to assemble raw and manufactured articles for brief display and to be commercial.

Design.—Some of the later "sample" fairs have made use of temporary and flimsy structures, like booths in a market place. The larger of such fairs, however, have inclined to use great permanent buildings, however scattered. Special expositions, following the example set by London with the Crystal Palace, have erected on such open spaces as were available huge structures, at least one of which is usually permanent.

Breadth, freedom and largeness of scale were given to all planning and designing for world's fairs by Daniel H. Burnham and his associates in Chicago for the Columbian exposition of 1893. These men worked on 600 ac. of undeveloped park land as on a blank piece of paper. They conceived an entire investiture for the exposition—landscape, buildings and sculpture—and had the satisfaction of seeing their broad conception grow into a reality. The firm of Carrère and Hastings, for the Buffalo Pan-American exposition of 1901, essayed to represent in the buildings of one major section of their plan what man had gained after long years of strife with the elements, and in the buildings of the corresponding section the elements themselves. The struggle between these forces was intended to be denoted by positive colours of red, blue, green and gold, which graduated gently into tints until an electric tower was reached, where the prevailing tone was a deep green as nearly as possible the colour of Lake Erie. The tower, which had works of sculpture on its four corners at the base, was of a light ivory and was tinted with blue, green and gold, which grew fainter as the top was reached, terminating in a gilt figure of the Goddess of Light. St. Louis, in 1904, employed the largest area so far given to such a plan, about 800 acres. The programme of obtaining an open space and planning for it a series of entirely new buildings in a setting of lagoons, drives, gardens, fountains and sculpture, all to combine in a single, new, comprehensive art expression, was generally adopted. E. L. Masqueray was the architect and designer-in-chief.

By the time the San Francisco exposition for 1915 was planned, the designing of exposition buildings and grounds had become almost a profession. One of Burnham's later associates, Edward

ARCHITECTURE AT THE PARIS EXPOSITION DES ARTS DECORATIFS

1. Garden on the terrace of the railway station, by J. H. Lambert. **2.** Pavilion of Galeries Lafayette, by J. Hiriart, G. Triboul and G. Beau. **3.** Promenade before Austrian Pavilion by Josef Hoffmann. **4.** Pavilion for Crès, bookseller, designed to represent enormous books, with top in white, yellow and bronze. **5.** Sèvres Pavilion, and Garden, by Patout et Ventre. **6.** Sèvres Pavilion. **7.** Polish Pavilion with glass top, by Czajkowski. **8.** Pavilion of a collector, showing façade and garden by P. Patout

H. Bennett, was employed as architect of the grounds, and he produced a novel plan—a series of courts which met the climatic need of trapping the sunlight and sheltering the visitors from the brisk breezes that blow across San Francisco bay in midsummer. This led to an architectural treatment of the structures by courts, so that each designer in reality did the sides of four buildings, while other designers did the outer walls of the same buildings. The second respect in which the designing for San Francisco was unusual was that Jules Guerin was chosen as head of the department of colour, and while working in co-operation with the architects he went somewhat independently to work planning for a freer use of colour than in any other group of modern times. Several schools of architecture were represented in the designing of the courts—Moorish-Spanish, Romanesque, Italian Renaissance; and it is remarkable that with the extensive use of pink, tan, orange, red, yellow and green, the effect of the whole was harmonious and rich. San Diego in the same year employed only one architect, Bertram G. Goodhue, and he adapted the more ornate architecture of Spain to the needs of modern life. In contrast with the exterior application of colour at San Francisco, the colour was built into the structures of San Diego by the use of tiles and was introduced into the setting by truly magnificent planting.

For the British empire exhibition at Wembley (1924–25), four general buildings and 21 special buildings were erected of concrete on the most simple of classic lines. Variety and colour were introduced into the composition by the kiosks, band-stands and pavilions. Rio de Janeiro in 1922 and Seville and Barcelona for 1928 and 1929 adopted comprehensive plans. All designing and displays for the Paris Exposition des Arts Décoratifs of 1925 were required "to present the character of art and to be of strictly modern tendency." Nothing was to be exhibited which to the authorities would seem to be an expression or an imitation of any ancient style. The effect was to bring to one centre illustrations of the increasing radicalism that has marked recent design throughout continental Europe. Frankly temporary, the new constructions and the treatments of the gardens and plazas offered the appeal of lightness, brilliance and the bizarre.

Influence.—Fairs and expositions of all sorts must be assumed to exercise an influence that is immediate, continuous, far-reaching. Two years sufficed to carry to all the centres of the Occident the influence of the Exposition des Arts Décoratifs of 1925. Its diagonal lines, its "philosophical" and original motifs, its independence of tradition, its studied avoidance of natural and pictorial forms, were soon reflected in design.

To the San Diego exposition and the ascendancy of Goodhue in the United States is attributed the striking spread of Moorish-Spanish architecture throughout the southern States of the American Union. In Florida the projectors of the large east coast hotels had long before proposed this type of design as especially suited to that section. But it was not until great numbers of real estate promoters and owners had been made familiar with buildings of this small exposition, and in a lesser degree with those of San Francisco, that the movement became truly popular.

Probably the most impressive evidence of the influence of such an exposition is provided by the exposition in Chicago in 1893. The magnificence of the court of honor, the manifest harmony suggested by a uniform cornice line, the dignity and grace of the classic orders, came to the people of the United States and Canada as something akin to a revelation. Rough stone and imitations of the designs of H. H. Richardson suddenly ceased to be fashionable even in remote localities. The public buildings erected in the United States from 1893 to 1915 were, with few exceptions, built on the more usual classic lines.

For the making of parks city authorities were more easily persuaded to employ landscape architects. Burnham's personal influence moved officials of Chicago, Cleveland and Washington, D.C., to enter upon the study of street extensions and the improvement of existing streets with regard for their relation to a general economic and functional plan for the city. With Charles F. McKim, Augustus St. Gaudens and F. L. Olmsted, he accepted appointment to the Washington park commission and provided the U.S. Senate with a development of the original plan of L'Enfant and Ellicott for the capital city. Social workers, engineers and architects related the teachings of Burnham and his associates to the problems of rapidly growing cities in new countries, and, traceable primarily to this exposition, there came into existence the new efficiency and correspondingly new profession of city planning (*see* TOWN AND CITY PLANNING).

BIBLIOGRAPHY.—Few works on exhibitions, beyond the official reports and the compilations of views, are available. Walford, *Fairs, Past and Present* (1883); P. Huveline, *Essai historique sur le droit des marchés et des foires* (1897); M. Benjamin, *The Architecture of Exhibitions* (1910). Chapters on the influence of the Chicago fair are contained in C. Moore, *A Story of Architecture in America* (1927); Daniel H. Burnham, *Architect and Planner of Cities* (1921). Of the official reports, F. M. Todd's *Panama-Pacific International Exposition* (1921) provides an account of the planning of the exposition in San Francisco in 1915. (A. D. A.)

EXHUMATION: *see* BURIAL.

EXILARCH, in Jewish history, "Chief, or Prince, of the Captivity." The Jews of Babylonia, after the destruction of the First Temple, were termed the people of the "Exile." Hence the head of the Babylonian Jews was the Exilarch (in Aramaic *Resh Galutha*). The office was hereditary and carried with it considerable power. Some traditions regarded Jehoiachin, the captive king of Judah, as the first exilarch, and all later holders of the dignity claimed to be scions of the house of David. The office comes into prominence under the Arsacids and Sassanids. In 520 an attempt was made to secure political autonomy for the Jews by force, but the exilarch who led the movement (Mar Zutra) was executed. For some time thereafter the office was in abeyance, but it was revived under Muslim rule with enhanced dignity. From the middle of the 7th century the exilarchs were all descendants of Bostanai (*q.v.*) through whom "the splendour of the office was renewed and its political position made secure" (Bacher). The last exilarch of importance was David, son of Zakkai (d. 940), whose contest with Saadiah had momentous consequences. A persecution culminating in the death of his descendant Hezekiah (1040) put an end to the grandeur of the institution. However (contrary to what was formerly supposed), it continued sporadically until late in the 13th century, having as its counterpart the office of *Nagid* in Egypt and *Nasi* in Palestine and elsewhere.

A vivid account has come down of the ceremonies at the installation of a new exilarch during the period of Muslim rule, from which most of our knowledge dates. Homage would be paid on that occasion by the heads of the rabbinical academies each of whom was called Gaon. The exilarch could excommunicate, appoint judges, exact taxes, and had in addition considerable secular jurisdiction. An hyperbolical description of the glories of the office is given in Disraeli's novel *Alroy*.

EXILE, banishment from one's native country by the sovereign authority. In a general sense exile is applied to prolonged absence from one's country either through force of circumstances or when undergone voluntarily. Among the Greeks, in the Homeric age, banishment (φυγή) was sometimes inflicted as a punishment by the authorities for crimes affecting the general interests, but is chiefly known in connection with cases of homicide. With these the State had nothing to do; the punishment of the murderer was the duty and privilege of the relatives of the murdered man. Unless the relatives could be induced to accept a money payment by way of compensation (ποινή, weregeld; *see* especially Homer, *Iliad*, xviii. 497), in which case the murderer was allowed to remain in the country, his only means of escaping punishment was flight to a foreign land. If, during his self-imposed exile, the relatives expressed their willingness to accept the indemnity, he was at liberty to return and resume his position in society.

In later times banishment is (1) a legal punishment for particular offences; (2) voluntary.

1. Banishment for life with confiscation of property was inflicted upon those who destroyed or uprooted the sacred olives at Athens; upon those who remained neutral during a sedition (by a law of Solon which subsequently fell into abeyance); upon those who gave refuge to or received on board ship a man who had fled to avoid punishment; upon those who wounded with intent to kill and those who prompted them to such an act (it is uncertain whether in this case exile was for life or temporary); upon anyone who wilfully murdered an alien; for impiety. Certain political crimes were also similarly punished—treason, laconism, sycophancy (*see* SYCOPHANT), attempts to subvert existing decrees. For the peculiar form of banishment called OSTRACISM, *see* separate article.

2. Citizens sometimes voluntarily left the country for other reasons (debt, inability to pay a fine). Since extradition was only demanded in cases of high treason or other serious offences against the State, the fugitive was not interfered with. He was at liberty to return after a certain time had elapsed.

Little is known about exile as it affected Sparta and other Greek towns, but it is probable that the same conditions prevailed as at Athens.

At Rome, in early times, exile was not a punishment, but rather a means of escaping punishment. Before judgment had been finally pronounced it was open to any Roman citizen condemned to death to escape the penalty by voluntary exile (*solum vertere exsilii causa*). To prevent his return, he was interdicted from the use of fire and water; if he broke the interdict and returned, anyone had the right to put him to death. The *aquae et ignis* (to which *et tecti* "shelter" is sometimes added) *interdictio* is variously explained as exclusion from the necessaries of life, from the symbols of civic communion, or from "the marks of a pure society, which the criminal would defile by his further use of them." Subsequently (probably at the time of the Gracchi) it became a recognized legal penalty, practically equivalent to "exile," taking the place of capital punishment. The criminal was permitted to withdraw from the city *after* sentence was pronounced; but in order that this withdrawal might as far as possible bear the character of a punishment, his departure was sanctioned by a decree of the people which declared his exile permanent. Authorities are not agreed whether this exile by interdiction entailed loss of *civitas;* according to some this did not ensue until (as in earlier times) the criminal had assumed the citizenship of the State in which he had taken refuge and thereby lost his rights as a citizen of Rome, while others hold that it was not until the time of Tiberius (A.D. 23) that *capitis deminutio media* became the direct consequence of trial and conviction. *Interdictio* was the punishment for treason, murder, arson and other serious offences which came under the cognizance of the *quaestiones perpetuae* (permanent judicial commissions for certain offences); confiscation of property was only inflicted in extreme cases.

Under the Empire *interdictio* gradually fell into disuse and a new form of banishment, introduced by Augustus, called *deportatio,* generally *in insulam,* took its place. For some time the two probably existed side by side. *Deportatio* consisted in transportation for life to an island (or some place prescribed on the mainland, not of Italy), accompanied by loss of *civitas* and all civil rights, and confiscation of property. The most dreaded places of exile were the islands of Gyarus, Sardinia, an oasis in the desert (*quasi in insulam*) of Libya; Crete, Cyprus and Rhodes were considered more tolerable. Large bodies of persons were also transported in this manner; thus Tiberius sent 4,000 freedmen to Sardinia for Jewish or Egyptian superstitious practices. *Deportatio* was originally inflicted upon political criminals, but in course of time became more particularly a means of removing those whose wealth and popularity rendered them objects of suspicion. It was also a punishment for the following offences: adultery, murder, poisoning, forgery, embezzlement, sacrilege and certain cases of immorality.

Relegatio was a milder form of *deportatio.* It either excluded the person banished from one specified district only, with permission to choose a residence elsewhere, or the place of exile was fixed. *Relegatio* could be either temporary or for life, but it did not in either case carry with it loss of *civitas* or property, nor was the exile under military surveillance, as in the case of *deportatio.* Thus, Ovid, when in exile at Tomi, says (*Tristia,* v. xi.): "he, *i.e.,* the emperor, has not deprived me of life, nor of wealth, nor of the rights of a citizen . . . he has simply ordered me to leave my home." He calls himself *relegatus,* not *exsul.*

In later writers the word *exsilium* is used in the sense of all its three forms—*aquae et ignis interdictio, deportatio* and *relegatio.*

EXILI, an Italian chemist and poisoner in the 17th century. His real name was probably Nicolo Egidi or Eggidio. Tradition credits him with having been originally the salaried poisoner at Rome of Olympia Maidalchina, the mistress of Pope Innocent X. Subsequently he became a gentleman in waiting to Queen Christina of Sweden, whose taste for chemistry may have influenced this appointment. In 1663 he was imprisoned in the Bastille. Here he is said to have made the acquaintance of Godin de Sainte-Croix, the lover of the marquise de Brinvilliers (*q.v.*). After three months' imprisonment, powerful influences secured Exili's release, and in 1681 he was again in Italy, where he married the countess Fantaguzzi, second cousin of Duke Francis of Modena.

EXMOOR FOREST, a high moorland in Somersetshire and Devonshire, England. The uplands of this district are bounded by the alluvial plain of Sedgemoor (east), the basin of the Exe (south), that of the Taw (west) and the Bristol channel (north), and in this area is included also the Brendon and Quantock hills. The area of Exmoor above 1,000 ft. is 120 sq.m. The geological formation is Devonian. The ancient forest (area 20,000 acres) was enclosed in 1815. Large tracts are still uncultivated; and the wild red deer and native Exmoor pony are characteristic of the district. The highest point is Dunkery Beacon (1,707 ft.), but Span Head is 1,618 ft., and a height of 1,500 ft. is exceeded at several points. The Exe, Barle, Lyn and other streams, traversing deep picturesque valleys except in their uppermost courses, are in favour with trout fishermen. The villages Exford, Withypool and Simonsbath, with Lynton and Lynmouth on the coast, afford centres for tourists and sportsmen. Exmoor is noted for its stag hunting.

EXMOUTH, EDWARD PELLEW, 1ST VISCOUNT (1757–1833), English admiral, was born at Dover, on April 19, 1757. In 1770 he entered the navy, where his great ability soon became apparent. He had no opportunity of active service till 1776, when his action at the battle of Lake Champlain gained him a lieutenant's commission and the command of the "Carleton." In 1777 he commanded a brigade of seamen in General Burgoyne's American campaign, and three years later he compelled three French privateers to run ashore, for which act he received the rank of post-captain. During the French revolutionary wars he commanded the "Nymph" and the "Arethusa," and then hoisted his flag as a squadron commander in the "Indefatigable"; for his bravery in boarding the wrecked transport "Dutton," and the measures which he adopted to save the lives of all on board, he was in 1796 created a baronet. In 1798 he joined the channel fleet, and in command of the "Impétueux" (74) took part in several actions with great distinction.

In 1802 Pellew was elected M.P. for Dunstable. In 1804 he became commander-in-chief in India, where he entirely cleared the seas of French cruisers, and secured complete protection for British commerce. He returned to England in 1809, held the North Sea (1810) and Mediterranean (1811) command, and in 1814 was created Baron Exmouth. When the dey of Algiers, in 1816, violated the treaty for the abolition of slavery, Exmouth was

directed to attack the town. Accordingly, on Aug. 26, he engaged the Algerine battery and fleet, and after a severe action, set on fire the arsenal and every vessel of the enemy's fleet, and shattered the sea defences into ruins. For this victory Exmouth was advanced to the dignity of viscount. Shortly before his death, on Jan. 23, 1833, he was made vice-admiral.

His descendant, Charles Ernest Pellew (b. 1863), became the 7th viscount in 1923.

Exmouth's second son, Sir Fleetwood Broughton Reynolds Pellew (1789–1861), was like his father an admiral. The third son was George Pellew (1793–1866), author and divine, who married Frances (d. 1870), daughter of the prime minister, Lord Sidmouth, whose biography he wrote (*The Life and Correspondence of Henry Addington, 1st Viscount Sidmouth*, 1847).

Exmouth had a brother, Sir Israel Pellew (1758–1832), also an admiral, who was present at the battle of Trafalgar.

A *Life* of the 1st viscount, by Edward Osler, was published in 1835.

EXMOUTH, a market-town, seaport and watering-place in the Honiton parliamentary division of Devonshire, England, on the east bank at the mouth of the river Exe, 8½ m. S.E. by S. of Exeter and 5 m. W. of Budleigh Salterton by either of those routes on the Southern railway. Pop. of urban district (1921) 13,606. In the 18th century it consisted of a fishing village at the base of Beacon hill, a height commanding fine views over the estuary and the English channel. After its more modern terraces were built up the hillside, Exmouth became one of the leading seaside resorts in Devon. Its excellent bathing and the beauty of its coast and moorland scenery attract many visitors in summer, while it is frequented in winter by sufferers from pulmonary disease. The climate is unusually mild, as a range of hills shelters the town on the east. A promenade runs along the sea wall; there are golf links and public gardens, and the port is a favourite yachting centre, a regatta being held annually. Near the town is a natural harbour called the Bight. Docks for the river shipping were built in 1869. A steam ferry connects Exmouth with Starcross on the west shore of the estuary and a station on the G.W. railway. The local industries include fishing, brick-making and the manufacture of Honiton lace. Exmouth was early a place of importance, and in 1347 contributed 10 vessels to the fleet sent to attack Calais. It once possessed a fort or "castelet," designed to command the estuary of the Exe, which was garrisoned for the king during the Civil War, and captured in 1646.

EXODUS, BOOK OF, in the Bible, a book of the Old Testament which derives its name, through the Greek, from the event which forms the most prominent feature of the history it narrates, viz., the deliverance of Israel from Egypt. Strictly speaking, however, this title is applicable to the first half only, the historical portion of the book, and takes no account of those chapters which describe the giving of the Law on Mt. Sinai, nor of those which deal with the Tabernacle and its furniture.

The book of Exodus, like the other books of the Hexateuch, is a composite work which has passed, so to speak, through many editions; hence the order of events which it sets forth cannot lay claim to any higher authority than that of the latest editor. Moreover, the documents from which the book has been compiled belong to different periods in the history of Israel, and each of them, reflects the standpoint of the age in which it was written. The contents are not of equal historical value, but greater weight naturally attaches to the earlier documents in those cases in which the sources are at variance with one another. The contents may be most conveniently treated under three main heads: (*a*) the historical portion (ch. i.–xviii.); (*b*) the sections dealing with the giving of the Law (xix.–xxiv., xxxii.–xxxiv.), and (*c*) the construction of the Tabernacle and its furniture (xxv.–xxxi., xxxv.–xl.).

(*a*) (1) *Israel in Egypt and the Exodus* (ch. i.–xviii.). The narrative which is derived from JE sets forth the rise of a new king in Egypt, who endeavoured to check the growing strength of the children of Israel; it thus prepares the way for the birth of Moses, his early life in Egypt, his flight to Midian and marriage with Zipporah, the theophany at Mt. Horeb, and his Divine commission to deliver Israel from Egypt. The two sources betray their divergent origin and point of view. J presents the Israelites as dwelling apart in the province of Goshen: to meet the danger of their rapid increase the Egyptians subject them to severe measures of repression. At his call Moses is given three signs to attest his Divine commission, one of which is wrought with his rod. He and the elders of Israel are bidden to interview Pharaoh and to request that they may go three days' journey into the wilderness for the purpose of sacrifice. The request is met by the imposition of harsher conditions of service. According to E the Israelites dwell among the Egyptians, and two midwives are sufficient for the needs of the growing population. Aaron, who occupies a prominent position throughout this narrative, is appointed to be Moses' spokesman with the people, and the only sign given to Moses is the promise that after their release the people "shall serve God upon this mountain." Moses and Aaron are directed to demand the release of Israel, an event which will be marked by a spoiling of the Egyptians. Finally not one but many signs are to be performed with the rod, referring probably to the plagues of Egypt, which were invariably wrought according to E by "the rod of God." The section concludes with P's parallel account (vi. 2–vii. 13) of the events recorded in cc. iii.–v. Apart from its literary style this narrative presents the following points of variation: (1) The people refuse to listen to Moses; (2) Aaron is appointed to be Moses' spokesman not with the *people* but with Pharaoh; (3) one sign is given with Aaron's rod, which is turned into a reptile (*tannin*), not a serpent (*nāḥāsh* iv. 3), before Pharaoh.

(2) vii. 14–xi. 10. *The First Plagues of Egypt.* In this section the three main sources are clearly marked off from one another both by their linguistic features and by their difference of representation. The principal source is J from which are derived six plagues, viz., killing of the fish in the river, frogs, insects, murrain, hail, locusts and the threat to slay all the first-born. The plagues are represented as mainly due to natural causes and follow a natural sequence. Other distinctive features of J's narrative are: (1) Moses alone is bidden to interview Pharaoh; (2) on each occasion he makes a formal demand; (3) on Pharaoh's refusal the plague is announced, and takes place at a fixed time without any human intervention; (4) when the plague is sent, Pharaoh sends for Moses and entreats his intercession, promising in most cases to accede in part to his request; when the plague is removed, however, the promise is left unfulfilled, the standing phrase being "and Pharaoh's heart was heavy," or "and Pharaoh made heavy his heart"; (5) the plagues do not affect the children of Israel in Goshen. E's account (water turned into blood, hail, locusts) is more fragmentary, having been doubtless superseded in most cases by the fuller and more graphic narrative of J, but the plague of darkness (x. 20–23, 27) is found only in this source. As contrasted with J the narrative emphasizes the miraculous character of the plagues. They are brought about by "the rod of God," which Moses wields, the effect being instantaneous and all-embracing. The Israelites are represented as living among the Egyptians, and enjoy no immunity from the plagues, except that of darkness. Their departure from Egypt is deliberate; the people have time to borrow raiment and jewels from their neighbours. E regularly uses the phrase "and Pharaoh's heart was strong," or "and Yahweh made strong Pharaoh's heart" and "he would not let the children of Israel (or, them) go." In the priestly narrative (P) the plagues assume the form of a trial of skill between Aaron, who acts at Moses' command, and the Egyptian magicians, and thus connect with vii. 8–13. The magicians succeed in turning the Nile water into blood, and in bringing up frogs, but they fail to bring forth lice, and are themselves smitten with boils; the two last-named plagues have no parallel either in J or E. Throughout the P sections Aaron is associated with Moses, and the regular command given to the latter is, "Say unto Aaron": no demand is ever made to Pharaoh, and the description of the plague is quite short. The formula employed by P is similar to that of E, but it is distinguished by the addition of "and he hearkened not unto them as Yahweh had spoken."

(3) xii. 1–xiii. 16. *The Last Plague, the Deliverance from*

Egypt, the Institution of the Passover and of the Feast of Unleavened Cakes, the Consecration of the First-born. This section presents repetitions and inconsistencies. Thus J's regulations for the Passover (xii. 21–23, 27*b*) are a parallel and divergent account of those given in *vv.* 1–13 (P). In these verses the choice of the lamb and the manner in which it is to be eaten constitute the essential feature, the smearing with the blood being quite secondary; in *vv.* 21 *seq.* the latter point is all-important, and no regulations are given for the paschal meal (which, possibly, formed no part of J's original account). Similarly the institution of the Feast of *Mazzoth,* or Unleavened Cakes (xiii. 3–10J), does not form the sequel to the regulations laid down in xii. 14–20 (P), but is independent of them: it omits all reference to the "holy convocations" and to the abstinence from labour, and is obviously simpler and more primitive. J's account, again, makes important exceptions (xiii. 11–13) to the severe enactment of P with reference to the first-born (xiii. 1). The description of the smiting of the first-born of Egypt is mainly derived from J, who sees in the Feast of *Mazzoth* a perpetual reminder of the haste with which the Israelites fled from Egypt.

(4) xiii. 17–xv. 21. *The Crossing of the Red Sea.* According to J the children of Israel departed from Egypt under the guidance of Yahweh, who leads them by day in a pillar of cloud and by night in a pillar of fire (xiii. 21, 22). On hearing of their flight Pharaoh at once starts in pursuit. The Israelites, terrified by the approach of the Egyptians, upbraid Moses, who promises them deliverance by the hand of Yahweh. Yahweh then causes a strong east wind to blow all that night, which drives back the waters from the shallows, and so renders it possible for the host of Israel to cross over. The Egyptians follow, but the progress of their chariots is hindered by the soft sand, and in the morning they are caught by the returning waters. The story, however, has been combined with the somewhat different account of E, which doubtless covered the same ground, and also with that of P. According to the former Moses divided the waters by stretching out his rod, thus presupposing that the crossing took place by day, and the dark cloud which divided the two hosts was miraculously caused by the angel of God. P also represents the sea as divided by means of Moses' rod, but heightens the effect by describing the crossing as taking place between walls of water. J's version of the Song of Moses probably does not extend beyond xv. 1, and has its counterpart in the very similar song of Miriam (E), in *vv.* 20, 21. The rest of the song (*vv.* 2–18) is probably the work of a later writer; for these verses set forth not only the deliverance from Egypt, but also the entrance of Israel into Canaan (*vv.* 13–17), and further presuppose the existence of the temple (*vv.* 13*b*, 17*b*).

(5) xv. 22–xviii. 27. *Incidents in the Wilderness.* The narrative of the first journeying in the wilderness (xv. 22–xvii. 7) presents a series of difficulties which probably owe their origin to the editorial activity of R^P, who appears to have transferred to the beginning of the wanderings a number of incidents which rightly belong to the end. The concluding verses of ch. xv. contain J's account of the sweetening of the waters of Marah. Then follows (ch. xvi.) P's version of the sending of the manna and quails. Neither of these stories, however, is in its proper position. The story of the manna belongs to a later period *after* the departure from Mt. Sinai, and had originally no immediate connection with the story of the quails. The latter, which is incomplete, is derived from Num. xi. (JE) where the incident is placed at the end of the wanderings.

xvii. 8–16. *The Battle with Amalek at Rephidim.* This incident is derived from E, but is clearly out of place in its present context. Its close connection with the end of the wanderings is shown by (*a*), the description of Moses as an infirm old man; (*b*) the rôle played by Joshua in contrast with xxiv. 13, xxxiii. 11, where he is introduced as a young man and Moses' minister; and (*c*) the references elsewhere to the home of the Amalekites who dwelt in the south or south-west of Judah near Kadesh.

Ch. xviii. *The visit of Jethro to Moses and the appointment of judges.* This story, like the preceding one, is mainly derived from E and is also out of place. Allusions in the chapter itself point unmistakably to a time just before the departure from Sinai-Horeb, and this date is confirmed both by Deut. i. 9–16 and by the parallel account of J in Num. x. 29–32.

(*b*) Ch. xix.–xxiv., xxxii.–xxxiv. The contents of these chapters, which, owing to their contents, form the most important section in the book of Exodus, may be briefly analysed as follows: In ch. xix. we have a two-fold description of the theophany on Mt. Sinai (or Horeb), followed by the Decalogue in xx. 1–17. Alongside of this code we find another dealing in part with the civil and social (xxi. 2–xxii. 17), in part with the religious life of Israel, the so-called Book of the Covenant, xx. 22–xxiii. 19. Ch. xxiv. contains a composite narrative of the ratification of the covenant. In chs. xxxii. and xxxiii. we have again two narratives of the sin of the people and of Moses' intercession, while in ch. xxxiv. we are confronted with yet another early code, which is practically identical with the religious enactments of xx. 22–26; xxii. 29, 30; xxiii. 10–19.

Ch. xix. contains two parallel accounts of the theophany on Horeb-Sinai, from E and J respectively, which differ materially from one another. According to the former, Moses is instructed by God (Elohim) to sanctify the *people* against the third day (*vv.* 9*a*, 10, 11*a*). This is done and the people are brought by Moses to the foot of the mountain (Horeb), where they hear the divine voice (14–17, 19). In J, on the other hand, it is the *priests* who are sanctified, and great care must be taken to prevent the people from "breaking through to gaze" (20–22). In this account the mountain is called "Sinai" throughout, and "Yahweh" appears instead of "Elohim." *Vv.* 3*b*–8 should follow after xx. 21.

Of the succeeding legislation in xx.–xxiii., xxxii.–xxxiv., undoubtedly the earlier sections are xx. 22–26; xxii. 29, 30; xxiii. 10–19, and xxxiv. 10–26, which contains regulations with regard to worship and religious festivals, and form the basis of the covenant made by Yahweh with Israel on Horeb-Sinai, as recorded by E and J respectively. The narrative which introduces the covenant laws of J has been preserved partly in its present context, ch. xxxiv., partly in xxiv. 1, 2, 9–11; the narrative of E, on the other hand, has in part disappeared owing to the interpolation of later material, in part has been retained in xxiv. 3–8. J's narrative xxiv. 1 *seq.*, 9–11 clearly forms the continuation of xix. 20 *seq.*, 11*b*, 13, 25, but the introductory words of *v.* 1, "and unto Moses he said," point to some omission. Originally, no doubt, it included the recital of the Divine instructions to the people in accordance with xix. 21 *seq.*, the statement that Yahweh came down on the third day, and that a long blast was blown on the trumpet (or ram's horn). From xxiv. 1 *seq.* we learn that Moses and Aaron, Nadab and Abihu, and 70 of the elders were summoned to the top of the mountain, but that Moses alone was permitted to approach Yahweh. Then followed the theophany, and, as the text stands, the sacrificial meal (9–11). The conclusion of J's narrative is given in ch. xxxiv., which describes how Moses hewed two tables of stone at Yahweh's command, and went up to the top of the mountain, where he received the words of the covenant and wrote them on the tables. As it stands, however, this chapter represents the legislation which it contains as the renewal of a former covenant, also written on tables of stone, which had been broken (1*b*, 4*a*). But the document from which the chapter, as a whole, is derived, is certainly J, while the previous references to tables of stone and to Moses' breaking them belong to the parallel narrative of E. Moreover, the covenant here set forth (*v.* 10 *seq.*) is clearly a new one, and contains no hint of any previous legislation, nor of any breach of it by the people. In view of these facts we are forced to conclude that 1*b* ("like unto the first . . . brakest"), 4*a* ("and he hewed . . . the first") and *v.* 28 ("the ten words") formed no part of the original narrative, but were inserted by a later Deuteronomic redactor. In the view of this editor the Decalogue alone formed the basis of the covenant of Sinai-Horeb, and in order to retain J's version, he represented it as a renewal of the tables of stone which Moses had broken.

The legislation contained in xxxiv. 10–26, which may be described as the oldest legal code of the Hexateuch, is almost entirely religious. The parallel collection of E is preserved in xx. 24–26, xxiii. 10–19, to which we should probably add xxii. 29–31 (for

which xxiii. 19*a* was afterwards substituted). The two collections resemble one another so closely, in form and extent, that they can only be regarded as two versions of the same code. E has, however, preserved certain additional regulations with regard to the building of altars (xx. 24–26) and the observance of the 7th year (xxiii. 10, 11), and omits the prohibition of molten images (xx. 22, 23, appear to be the work of a redactor); xxiii. 20–33, the promises attached to the observance of the covenant, probably formed no part of the original code, but were added by the Deuteronomic redactor. The narrative of E relative to the delivery of these laws has disappeared, but xxiv. 3–8 clearly point back to some such narrative. These verses describe how Moses wrote all the words of the Lord in a *book* and recited them to the *people* (*v.* 7), as the basis of a covenant, which was solemnly ratified by the sprinkling of the blood of the accompanying sacrifices.

In the existing text the covenant laws of E are combined with a mass of civil and other legislation; and the title "Book of the Covenant" has usually been applied to the whole section, xx. 22–xxiii. 33. However, this section includes three distinct elements; (*a*) the "words" found in xx. 24–26, xxii. 29–31, xxiii. 10–19; (*b*) the "judgments," xxi. 2–xxii. 17; and (*c*) a group of moral and ethical enactments, xxii. 18–28, xxiii. 1–9; and though the last two groups are unmistakably derived from E, they cannot have formed part of the original "Book of the Covenant"; for the "judgments" consist of a number of legal decisions concerning points of civil law, which could not have been included in the covenant which the *people* (xxiv. 3) promised to observe. It is now generally admitted that the words "and the judgments" have been inserted in xxiv. 3*a* by the redactor to whom the present position of the "judgments" is due. The majority of critics adopt Kuenen's conjecture that the "judgments" were originally delivered by Moses on the borders of Moab, and that when D's revised version of Ex. xxi.–xxiii. was combined with JE, the older code was placed alongside of E's other legislation at Horeb. The third group of laws (xxii. 18–28, xxiii. 1–9) appears to have been added somewhat later than the bulk of xxi.–xxiii. It consists largely of moral injunctions affecting the individual, which cannot have found place in a civil code. At the same time, these additions must for the most part be prior to D, since many of them are included in Deut. xii.–xxvi.

It is obvious that the results obtained by the foregoing analysis of J and E have an important bearing on the history of the remaining section of E's legislation, viz., the *Decalogue* (*q.v.*), Ex. xx. 1–17 (=Deut. v. 6–21). At present the "Ten Words" stand in the forefront of E's collection of laws, and it is evident that they were already found in that position by the author of Deuteronomy, who treated them as the sole basis of the covenant of Horeb. The evidence, however, afforded (*a*) by the parallel version of Deuteronomy and (*b*) by the literary analysis of J and E not only fails to support this tradition, but excites the gravest suspicions as to the originality both of the *form* and of the *position* in which the Decalogue now appears. For when compared with Ex. xx. 1–17 the parallel version of Deut. v. 6 *seq.* is found to exhibit a number of variations, and in particular, assigns an entirely different reason for the observance of the Sabbath. It is probable that all the commandments were originally expressed in the form of single short sentences, and that the Decalogue in this form was promulgated after the completion of E, but before the writing of D. The two main incidents that precede the departure of the children of Israel from the mountain (Num. x. 29 *seq.*) are (1) the sin of the people, and (2) the intercession of Moses, of both of which a double account has been preserved.

(1) *The Sin of the People.* According to J (xxxii. 25–29) the people, during the absence of Moses, "break loose," *i.e.*, mutiny. Their behaviour excites the anger of Moses on his return, and in response to his appeal the sons of Levi arm themselves and slay a large number of the people: as a reward for their services they are bidden to consecrate themselves to Yahweh. The fragmentary form of the narrative is doubtless due to a later editor, who substituted the story of the golden calf (xxxii. 1–6, 15–24, 35), according to which the sin of the people consisted in direct violation of the 2nd commandment. At the instigation of the people Aaron makes a molten calf out of the golden ornaments brought from Egypt; Moses and Joshua, on their return to the camp, find the people holding festival in honour of the occasion; Moses in his anger breaks the tables of the covenant which he is carrying: he then demolishes the golden calf, and administers a severe rebuke to Aaron. The punishment of the people is briefly recorded in *v.* 35. This latter narrative, which is obviously inconsistent with the story of J, shows unmistakable traces of E. In its present form, however, it can hardly be original, but must have been revised in accordance with the later Deuteronomic conception.

(2) *Moses' Intercession.* The account of Moses' intercession has been preserved in J, though the narrative has undergone considerable dislocation. The true sequence of the narrative appears to be as follows: Moses is commanded to lead the people to Canaan (xxxiii. 1–3); he pleads that he is unequal to the task (Num. xi. 10*c*, 11, 12, 14, 15), and, presumably, asks for assistance, which is promised (omitted). Moses then asks for a fuller knowledge of Yahweh and his ways (xxxiii. 12, 13): this request also is granted (*v.* 17), and he is emboldened to pray that he may see the glory of Yahweh; Yahweh replies that his prayer can only be granted in part, for "man shall not see me and live"; a partial revelation is then vouchsafed to Moses (xxxiii. 18–23, xxxiv. 6–8): finally, Moses beseeches Yahweh to go in the midst of his people, and is assured that Yahweh's presence shall accompany them (xxxiii. 14–16, xxxiv. 9). The passage from Numbers xi., which is here included, is obviously out of place in its present context (the story of the quails), and supplies in part the necessary antecedent to Ex. xxxiii. 12, 13. A similar displacement has taken place with regard to Ex. xxxiv. 6–9, which clearly forms the sequel to xxxiii. 17–23. The latter passage, however, can hardly represent the conclusion of the interview, which is found more naturally in xxxiii. 14–16.

It is a plausible conjecture that the original narratives of J and E also contained directions for the construction of an ark, as a substitute for the personal presence of Yahweh, and also for the erection of a "tent of meeting" outside the camp, and that these commands were omitted by R^P in favour of the more elaborate instructions given in ch. xxv.–xxix. (P). The subsequent narrative of J (Num. x. 33–36, xiv. 44) implies an account of the making of the ark, while the remarkable descriptions in Ex. xxxiii. 7–11 (E) of Moses' practice in regard to the "tent of meeting" points no less clearly to some earlier statement as to the making of this tent. (According to Deut. x. 1 *seq.*, which is in the main a *verbal* excerpt from Ex. xxxiv. 1 *seq.*, Yahweh ordered Moses to make an ark of acacia wood *before* he ascended the mountain). The history of Exodus in its original form doubtless concluded with the visit of Moses' father-in-law and the appointment of judges (ch. xviii.), the departure from the mountain and the battle with Amalek (xvii. 8–16).

(*c*) *The Construction of the Tabernacle and its Furniture* (ch. xxv.–xxxi., xxxv.–xl.). It has long been recognized that the elaborate description of the Tabernacle and its furniture, and the accompanying directions for the dress and consecration of the priests, contained in ch. xxv.–xxxi., have no claim to be regarded as an historical presentment of the Mosaic Tabernacle and its service. The language, style and contents of this section point unmistakably to the hand of P; and it is now generally admitted that these chapters form part of an ideal representation of the post-exilic ritual system, which has been transferred to the Mosaic age.

Bibliography.—Fuller references will be found in the following works, which are especially worthy of mention: S. R. Driver, *Introd. to the Literature of the O.T.*, and "Exodus" in the *Camb. Bible;* B. W. Bacon, *The Triple Tradition of the Exodus* (Hartford, U.S.A., 1894), A. H. McNeile, *The Book of Exodus* (Westminster Commentaries, 1908); also the articles on "Exodus" by G. Harford-Battersby (Hastings, *Dict. Bib.*, vol. i.) by G. F. Moore, *Ency. Biblica*, vol. ii.
(J. F. S.)

EXODUS, THE, the name given to the escape of Israel from Egypt and their journey to Palestine (Gr. ἔξοδος). The narrative as we have it is derived from at least three accounts

which have been interwoven with one another. In outline the story is as follows. The Israelites are in bondage in Egypt, where their numbers and strength arouse the jealous fears of the Egyptian court. They are put to forced labour, and attempts are made to reduce their numbers by the slaughter of all male children. One child, Moses, is saved, partly through the intervention of an Egyptian princess, goes into exile to Midian, meets the God of the fathers of Israel, and is commissioned by Him to deliver His people. He returns and demands of Pharaoh that the Israelites shall be allowed to take a journey into the wilderness to share in a festival to Yahweh. The request of Moses is met by repeated refusal, and each refusal is followed by calamity sent by Yahweh. Finally, as the time for the sacrifice draws near, Yahweh himself (or his "angel") comes to Egypt, the festival is celebrated as best it can be in Egypt, and Yahweh slays the first-born of all Egyptians. Israel is hastily sent away, but is later pursued by Pharaoh, who overtakes the fugitives on the banks of the Red sea. Israel crosses safely (one of the traditions attributes this to unusual but natural causes, the other, and later, makes it miraculous), the Egyptian army follows but is drowned. Israel then makes its way to the sacred mountain, variously called Sinai and Horeb, and there enters into a solemn covenant of mutual adoption with Yahweh. An abortive attempt is made to enter Palestine from the south, and, nearly 40 years later, Israel moves east and north from the neighbourhood of the sacred mountain, and approaches Palestine from the east. Just before the crossing of Jordan and the entry into Palestine, Moses dies.

No certain reference to these events has yet been discovered in Egyptian records, unless, with Josephus and a few modern scholars, *e.g.*, Hall, we regard the story as an account of the expulsion of the Hyksos, seen from the Asiatic side. There are, nevertheless, the strongest grounds for regarding the narrative as historical in outline, though details cannot always be trusted. The whole of Israel's national and religious life was traced back to the covenant at the sacred mountain, and the memory of a divine deliverance from Egypt remained throughout history one of the most powerful factors in the national life. Some kind of disaster overtook the Egyptian troops by the Red sea, and we may regard as substantially accurate the older of the two narratives interwoven in Ex. xiv. 15–31. According to this the combination of a very high wind and a very low tide laid bare a wide stretch of sand normally covered by water. It was still firm when the Israelites crossed, but the Egyptians were caught by the tide returning under the sand, the wheels of their vehicles were clogged, and they themselves were first trapped by the quicksands and then overwhelmed by the water. There is, further, no reason to doubt the accuracy of the main outline of the other events already mentioned, though it is unlikely that the covenant between Yahweh and Israel involved the whole of the Law assigned to the period in the Pentateuch.

The date of the Exodus is still a matter of uncertainty. If the details of the oppression given in Ex. i. 11 are held to be accurate, then the Pharaoh of the oppression must be Rameses II., and the Pharaoh of the Exodus his son Merneptah. The main difficulty in accepting this date lies in the mention of Israel as a settled people of Palestine overthrown by Merneptah, occurring on an inscription of that king. This means that the 19th Dynasty is probably too late a period for the Exodus. Many scholars think that the invading Hebrews are to be identified with the Khabiru of the Tell el-Amarna tablets, or are to be included, wholly or in part, among these wilderness nomads, who attacked Palestine during the decline of the 18th Dynasty. This, on the whole the most probable suggestion, would throw the Exodus back to a point in or near the reign of Thothmes III. and make the 15th century B.C. the earliest possible period. (T. H. R.)

EXOGAMY. In every human society there are certain regulations which control the relation of the sexes and the selection of a mate. Intercourse between close blood-relations as brother and sister, father and daughter, and mother and son, is almost everywhere condemned. But among very many tribes it is forbidden both on grounds of consanguinity and because two individuals are members of the same social group. This prohibition, based upon common membership of a social group, is the law of *exogamy*. If the group is a territorial unit, *e.g.*, a village, the *exogamy* is local. More commonly, membership of the group concerned is determined by kinship, real or fictitious, as in the clan (*see* RELATIONSHIP SYSTEMS). Hence exogamy is often loosely used to indicate *clan exogamy*.

That exogamy prevents the marriage of all near relatives is true only if membership of the exogamous group is determined by descent reckoned through both parents, but this is very rare. Normally descent is traced through only one parent and it is therefore inevitable that certain close blood-relations will not belong to the same group and will therefore be possible mates for each other. Thus if a tribe is patrilineal a man can select wives from among his mother's sisters, her brother's daughters and her brother's son's daughters, and, were exogamy the only marriage prohibition, even his mother would be available to him. On the other hand, clan exogamy does prevent unions between people bearing no relationship to each other, since membership of a clan is dependent upon fictive, not blood relationship.

The rigidity with which the law of exogamy is observed varies considerably. Among some people a breach of it is regarded as incest; among others, though marriage is forbidden, extra-marital relations between clan members are tolerated; while in some cases even marriage can be condoned.

McLennan, who first coined the word, regarded it as the outcome of female infanticide which, by limiting the number of women available within the group, forced tribesmen to capture their wives from their neighbours, but increased knowledge of the facts has made this theory untenable. Another suggestion is that the horror of incest, supposedly innate, has extended to all those women whom, under the classificatory system of relationship, a man addresses by the term for "sister." On another view the original form was local exogamy arising from a natural distaste on the part of those who have been reared together to cohabit. Others believe it originated with Totemism (*q.v.*), while the diffusionists consider that it developed under special conditions in one place and spread thence throughout the world. (*See* ENDOGAMY.) (C. H. W.)

EXORCISM, the expulsion of evil spirits from persons or places by incantations, magical rites or other means. As a corollary of the animistic theory of diseases and of belief in Possession (*q.v.*), we find widely spread customs whose object is to get rid of the evil influences. These customs may take the form of a general expulsion of evils, either once a year or at regular intervals, either immediately by spells, purifications or some form of coercion; or by transfer to a scapegoat or other material vehicle. Among the means of compelling the evil spirits are assaults with warlike weapons or sticks, the noise of musical instruments or of the human voice, the use of masks, the invocation of more powerful good spirits, etc.; both fire and water are used to drive them out, and the use of iron is a common means of holding them at bay.

The term exorcism is applied more especially to the freeing of an individual from a possessing or disease-causing spirit; the means adopted are frequently the same as those mentioned above.

The professional exorcist was known among the Jews; in Greece the art was practised by women, as was charged against the mothers of Epicurus and Aeschines by the Stoics and Demosthenes. Exorcism in the early ages of the Christian church was frequently mentioned in the writings of the fathers. (*See* EXORCIST.) The rite of exorcism in connection with baptism, and a form of service for the exorcising of possessed persons, is still retained in the Roman ritual. The exorcist signs the possessed person with the figure of the cross, desires him to kneel, and sprinkles him with holy water; after which the exorcist asks the devil his name, and adjures him by the holy mysteries of the Christian religion not to afflict the person possessed any more. Then, laying his right hand on the demoniac's head, he repeats the form of exorcism as follows: "I exorcise thee, unclean spirit, in the name of Jesus Christ; tremble, O Satan, thou enemy of the faith, thou foe of mankind, who hast brought death into the world, who hast deprived men of life, and hast rebelled against

justice, thou seducer of mankind, thou root of evil, thou source of avarice, discord and envy." Houses and other places supposed to be haunted by unclean spirits are likewise to be exorcised with similar rites, and in general exorcism has a place in all the ceremonies for consecrating and blessing persons or things (*see* BENEDICTION).

W. King, *Babylonian Magic.* Modern ethnographical works deal fully with the subject.

EXORCIST, in the Roman Catholic church, the third grade in the minor orders of the clergy, between those of acolyte and reader. The office, which involves the right of ceremonially exorcising devils (*see* EXORCISM), is actually no more than a preliminary stage of the priesthood. The earliest record of the special ordination of exorcists is the 7th canon of the council of Carthage (A.D. 398).

EXOTIC, of foreign origin, not indigenous or native, a term usually applied to plants introduced from foreign countries. Figuratively, "exotic" conveys the sense of something rare, delicate or extravagant.

EXPATRIATION: *see* ALIEN; ALLEGIANCE; NATIONALITY AND NATURALIZATION.

EXPECTATION OF LIFE. The term expectation of life denotes the average number of years which the persons of a specified age, taken one with another, will live according to a given mortality table. (*See* LIFE TABLE.)

If of l_x persons aged exactly x, l_{x+1} survive to age $x+1$, l_{x+2} to age $x+2$, etc., then the average number of completed years of future life-time which the l_x persons will experience is $(l_{x+1}+l_{x+2}+\text{etc.})\div l_x$. This expression is represented by the symbol e_x, and is technically known as the *curtate expectation of life.* No allowance is included in the formula for that portion of life-time lived by each individual in the year of his death, which on the average will amount to approximately one-half of a year. The *complete expectation of life,* $\mathring{e}_x$, is therefore approximately equal to $e_x+\frac{1}{2}$. Also $\mathring{e}_x$ may be derived directly by means of the formula

$$\mathring{e}_x=\frac{L_{x+1}+L_{x+1}+\text{etc.}}{l_x}=\frac{T_x}{l_x}, \text{ where } L_x \text{ is equal to } \tfrac{1}{2}(l_x+l_{x+1})$$

and therefore denotes the population between the ages x and $x+1$, and T_x denotes the total population at age x and over.

There can be few technical terms so generally misunderstood and misused as the expectation of life. Several additional phrases have therefore been suggested as more appropriately describing the function, *e.g.,* the mean after life-time, the average after life-time, the mean duration of life and the average duration of life.

Amongst non-technical people the expectation of life has acquired a prestige greatly in excess of its actual merits. It is seldom used by actuaries, yet there appears to be a wide-spread impression that it forms the basis of all actuarial calculations involving the probabilities of survivorship. One of the most conspicuous instances of this popular fallacy is the assumption that the value of a life annuity is equivalent to that of an annuity-certain for a term of years corresponding to the expectation of life. The latter value is demonstrably in excess of the true value (*see* ANNUITY).

Another common misconception is that the expectation of life is an actuarial estimate of the number of years an individual may reasonably expect to live. The expectation of life is, however, an average value which is derived from a particular series of rates of mortality and, even if these rates accurately represent the future mortality experience at all ages, will correspond to the future life-time of only a very small proportion of the individuals concerned, the superior vitality of those who survive for a longer term being counterbalanced by the heavier mortality amongst the others.

Objections have recently been urged against the use of the expectation of life as an index of future mortality experience, owing to the fact that the progressive improvement in vitality revealed by successive investigations has suggested that it has become unreliable as a measure of the average future life-time of a body of lives. In such circumstances the figure that would have been the true expectation of life can only be determined after all the lives, whose experience is being reviewed, have died.

The expectation of life provides a means by which the mortality experience of different investigations may be compared. In recent years its use for this purpose has been the subject of much adverse criticism, and certainly as an instrument for detailed comparison it is not so satisfactory as several other criteria, *e.g.,* the probability of survivorship for an indicated period, say five or ten years. The expectation of life at a particular age does, however, provide a comprehensive figure which summarizes the experience at higher ages, and its value at birth is probably the best available statistical measure of the health conditions of a community. It is, therefore, of great value to medical officers and other statistical workers.

From the following table, which shows the expectation of life at specimen ages according to successive life tables, the improvement in the vitality of the population will be apparent.

Expectation of Life (Years), $\mathring{e}_x$.

EXPEDITIONARY FORCE, a body of troops sent overseas from its home country for operations in foreign territory. The name was applied during the World War to any important force sent out to a separate theatre of war under an independent commander. Thus the British Expeditionary Force (B.E.F.), the first to proceed overseas, fought in France and Belgium, and the Mediterranean Expeditionary Force (M.E.F.) in Gallipoli, Salonika and Egypt; and the United States troops in France were known as the American Expeditionary Force (A.E.F.).

EXPERIMENTAL EMBRYOLOGY. The study of general or comparative embryology reveals the fact that during their normal development, animals pass through a number of visibly different stages; each stage being characterized by the possession of various structures in a condition more or less well formed, as compared with earlier and later stages. In other words, the development of an animal can be unravelled into a series of sequences of structural patterns. Once the fact of these structural patterns has been established, it becomes interesting to enquire into the reasons why certain stages are preceded and followed by certain others; why the various organs of the body appear when and as they do; and whether the stages which follow one another in time, also follow one another as the effect does the cause.

Many such questions can be answered by applying directly to the animal, and artificially altering the conditions at the preceding stage. The process of interfering with the normal development is an experiment, and for this reason the study of the causal relationships between the various stages of development is called experimental embryology. The experiments themselves may consist of the removal or addition of definite parts of the embryo, or its subjection to abnormal conditions of temperature, electric currents, or chemical reagents, to give only a few examples. The experimental methods depend of course on the material which is being studied and the question which is being attacked. It must suffice to say, that in all cases, the results of an experimental operation must be interpreted in the light of a control experiment carried out alongside, and under normal conditions.

Development is usually held to start from the stimulation of the egg by Fertilization, or Parthenogenesis. Both these phenomena have yielded interesting results to experimentation. After stimulation of the egg, the development of the embryo consists of three main processes: cell-division, growth and differentiation.

Cell-division.—The starting-point of sexual and parthenogenetic development, the egg, is a single cell; whereas the adult animal to which it will give rise (excluding the Protozoa) contains countless cells. It is obvious that cell-multiplication must take place during development, and its importance is increased by the fact that it has a bearing on the other two processes, growth and differentiation. The volume of a cell cannot be increased above a certain limit without upsetting the convenient ratio of surface to volume. This means that when growth takes place and new living tissue is formed, the existing cells must multiply in order to accommodate the new material. At the same time, if cells are too highly differentiated (*see* below), they will be unable to divide. This is especially true of the cells of the nervous system of vertebrates; after a stage reached quite soon in man, the cells of his brain and spinal cord never divide again. According to Gurwitsch cell-division is a response to stimulation by ether waves of a length of between 1,900 and 2,000 Angström units. Apart from this theory, it must be confessed that very little is known as to the causes which result in the splitting of the cell-nucleus into two, and the subsequent division of the whole cell itself. For further information the reader is referred to the section on Parthenogenesis (artificial), for the active stimulus in causing an egg to start developing appears to be that which causes it to divide.

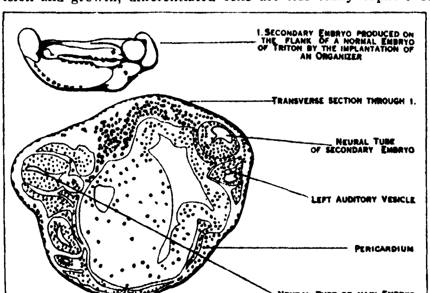
Growth.—Growth is increase in bulk. In an animal it may be caused by accumulation of non-living substances, as when an egg-cell is filled with yolk, or when the whole organism absorbs water. "True" growth, however, is the production of new living material, new protoplasm. This is one of the fundamental properties of life, which is constantly concerned in assimilating foreign matter and building it up into protoplasm. At the same time, protoplasm is always being broken down with wear and tear; but when the process of building-up (anabolism) is more active than that of breaking-down (katabolism) the result is growth.

It has been found that apart from the ordinary food-substances, others are necessary for growth. Chief among these are the vitamins, about which little is known, except that the effect which they produce appears to bear little relation to the quantity of them present. This would indicate that they act not as raw building-materials, but as ferments and catalysers accelerating the processes of building. Other substances are known whose property it is to accelerate the growth of tissues; these were discovered by means of experiments of growing pieces of tissue under aseptic conditions in small glass vessels, a technique which is called "tissue-culture," or growth "*in vitro.*" One of these substances, obtained from young embryos and hence called embryo-extract, encourages growth *in vitro,* which without it, would not take place. Another such substance is obtained by killing some cells and maintaining them at the normal temperature of the body, when they undergo a disintegrative process known as autolysis and furnish a substance (autolysed extract) which is a very powerful promoter of growth. The interest of this substance is increased by the fact that its effects are similar to those produced by extracts of malignant tumours (cancers).

For further details the reader is referred to the section on Growth, but before leaving the subject it must be mentioned that if growth takes place at unequal rates in the various parts of an embryo, the result will be an alteration of its shape; or in other words, its various parts which may previously have been similar, come to be different. This process is known as morphological (form-) differentiation. The importance of such changes of shape become obvious when it is realized that for example the fertilized egg of a man is spherical.

Differentiation.—The definition of morphological differentiation, or change of shape, has just been given. The earliest example of this in the development of most animals is the conversion of the solid egg-cell into a hollow ball composed of many smaller cells: the blastula. Later, this hollow ball is converted into a double-layered sac or gastrula, in which the original cavity of the ball (the blastocoel) is obliterated and its place taken by the cavity contained by the innermost of the two layers of the sac (the enteron, or future alimentary canal). Then, the sac elongates and the general shape of the future animal is roughed out. If the animal is a newt, the rudiments of the limbs and of the tail arise as little cones in which growth takes place more rapidly than in the neighbouring regions. All these cases are examples of morphological differentiation.

It is now necessary to turn to the cells of which the embryo is composed. These cells have been derived by repeated cell-division from the egg-cell, and as up to this stage there has been little or no increase in the total amount of living matter; the cells are thus much smaller than the original egg. If the egg contained yolk, then some of the cells produced from it will contain yolk, and others not, but otherwise, there is no visible difference (save, usually, size) between these cells. Later on, however, an actual difference between the cells becomes visible. Some become muscular cells, others nervous, others again form part of epithelia which line the cavities and surfaces of the embryo. Sheets of cells which have been modified in the same way form a tissue, and the process of modification which these cells have undergone, rendering them different from any other cells, is called histological (tissue-) differentiation. Undifferentiated cells, such as are found in the earliest stages of developing embryos, are called embryonic; and it is found that whereas embryonic cells are capable of rapid cell-division and growth, differentiated cells are less easily capable of



FROM MANGOLD & SPEMANN IN ROUX, "ARCHIV FUR ENTWICKLUNGSMECHANIK" (JULIUS SPRINGER)

FIG. 1.—THE "ARTIFICIAL" FORMATION OF AN EMBRYO

cell-division and therefore of growth. This is the connection between cell-division and differentiation referred to above; the reason for it must be that a differentiated cell no longer consists of pure protoplasm like an embryonic cell, but is encumbered with other inert substances which confer upon it its differentiation and hinder its division. The experimental evidence for this is obtained from tissue-cultures, in which it is found as a rule that the rate at which tissues grow is greater if they lose their differentiation (undergo dedifferentiation). Conversely, cells which divide too rapidly will not redifferentiate.

Cleavage.—The process of repeated cell-division whereby the egg-cell is fractionated into a number of smaller cells or blastomeres, is known as segmentation or cleavage. Whether the first cleavage separates the future right and left halves, or the future front and rear halves, or diagonal halves of the embryo, it is obvious that the first cleavage (and subsequent cleavages also) separate from one another parts of the embryo which have very different prospective fates in normal development. It therefore becomes important to enquire whether the origin of differentiation may be due to inequalities of cell-division during cleavage. In such a matter it is necessary to consider the division of the nucleus and the division of the body of the cell or cytoplasm.

Nuclear Division.—Experiments have proved that it is not in divisions of the nuclei during cleavage that differentiation originates. For by making eggs (of the frog, of the worm *Nereis,* or of the sea-urchin) undergo cleavage compressed between plates of glass, or by shaking them, the normal arrangement of the blastomeres is completely upset. After release from the glass plates, the embryos round themselves off again, and a given blastomere contains a nucleus which, in normal circumstances, would be situated in a different blastomere. Nevertheless, subsequent development of embryos operated upon in this way is normal. This can only mean that all the nuclei are equivalent, that their division has been strictly equal, and that they are not responsible for the origin of differentiation. The most elegant demonstration of this was obtained by tying a loop of fine hair round a fertilized but still undivided newt's egg, and constricting it almost into two, in the form of a dumb-bell. By this process, the nucleus was restricted to one side, in which it underwent division, while the other side had no nucleus at all. When the nucleated side contained sixteen nuclei, the hair-constriction was released slightly, and one nucleus was able to pass across the narrow bridge into the previously enucleate half. When the nucleus had passed, the hair was pulled tight and completely separated the two sides from one another. Both sides could develop normally into diminutive embryos, and as the nucleus which passed across could hardly be the same one in any two experiments, the experiment proves that all the sixteen nuclei were equivalent, and capable by themselves of ensuring normal development.

The experimental results just described are of fundamental importance, for they definitely disprove the celebrated Roux-Weismann theory of development. This theory attempted to attribute the origin of differentiation to unequal nuclear division during cleavage.

Cytoplasmic Division.—Turning now to the consideration of the nature of the division of the cytoplasm between the blastomeres during cleavage, the results obtained from experiments on different kinds of animals are apparently (but only apparently) contradictory. The method adopted is to separate the blastomeres from one another at the 2-cell, 4-cell or subsequent stages of cleavage.

In the sea-urchins, it is found that a single isolated blastomere from the 2-cell or the 4-cell stage is capable of developing into a perfect little larva, of half or quarter normal size respectively. These blastomeres which would normally have produced only one-half or one-quarter of the larva, are thus shown to be capable of regulating and giving rise to a whole. Eggs which divide into blastomeres capable of such regulation are called "regulation-eggs," and their blastomeres are called totipotent.

At the other end of the scale are eggs like those of the Ascidians (Sea-squirts) and Ctenophores (Comb-jellies or Sea-gooseberries), in which isolated blastomeres will only give rise to that which they would have ordinarily produced in normal development. Here, the blastomeres are differentiated and "set," like the separate pieces which make up the pattern of a mosaic. Such animals are consequently said to have "mosaic-eggs."

The difference between regulation-eggs and mosaic-eggs is really only due to a matter of time. In the regulation-eggs, the equivalence of the cytoplasm persists longer than in the mosaic-eggs, and in time, even in the sea-urchin, the different regions lose their totipotence. The mosaic-eggs, on the other hand, have portions of their cytoplasm determined for various fates already in the egg, before fertilization, and even when it is still in the ovary of its mother.

Experiments on cleavage therefore show that it is in determinations (as yet invisible) of the cytoplasm, or in the specialization of "organ-forming substances," that the first manifestations of differentiation are to be found. The next problem is to find out the cause for the determination and localization of these regions of the cytoplasm.

Polarity and Symmetry.—The eggs of frogs and newts occupy a peculiar position as regards the power of regulation, and therefore the degree of determination of the cytoplasm of their blastomeres. In the first place it must be realized that these eggs contain a fair amount of yolk which is accumulated in one (the lower, or so-called vegetative) hemisphere. The upper (or so-called animal) hemisphere contains little yolk. The distinction between the animal and vegetative hemispheres enables the comparison to be made between the frog or newt's egg and the globe, with its north and south poles. In other words, the egg has an axis and polarity, and the upper (or *animal)* pole of the egg will become the head of the future embryo, while the lower (or *vegetative*) pole will become the tail. The axis of the egg appears to be determined while it is still in the ovary by the orientation of the little arteries and veins; the animal pole is the region where the blood is brought to the egg-cell, and where the rate of protoplasmic activities is higher than elsewhere. This rate diminishes away from the animal pole and towards the vegetative hemisphere, so that the axis of the egg coincides with an axial gradient (*q.v.*). From experiments on the eggs of sea-urchins it is known that if the axial gradient of rate of activities of the protoplasm is abolished (*i.e.*, the rate of activities is made uniform), the embryo has no polarity. It is therefore legitimate to conclude that the localization of the site of the future head in the egg of a frog or newt, is due to that site being the highest point on an axial gradient, and that the axial gradient itself is determined by the greater stimulation which that site received as a result of the orientation of the blood-vessels in the ovary.

Thus far, the egg has a future head-end and tail-end, but it remains to determine which side shall be right, which left, and accordingly which dorsal and ventral. This determination is that of a plane of bilateral symmetry, which of course passes through the egg-axis. The plane of bilateral symmetry is as a rule fixed by the point of entry of the sperm fertilizing the egg, and in such a way that the mid-dorsal line of the embryo is the meridian exactly opposite that on which the sperm entered. The mid-dorsal line is taken as the most important, because it is on this meridian that the process of conversion of the blastula into the gastrula begins, by the overgrowth of the so-called dorsal lip of the blastopore. It will be shown below that the region of the dorsal lip of the blastopore is essential for the formation of the embryo. Its interest from the present point of view is the fact that an isolated blastomere of the 2-cell stage will develop normally into a perfect embryo if it contains a part of this region, but not if it lacks it. This region is therefore a cytoplasmic determination, or origin of differentiation (visible in the frog as the so-called grey crescent), and which is itself due to the point of entry of the sperm. This fact is proved by causing sperm to enter an egg on a selected meridian and observing its subsequent relation to the plane of bilateral symmetry; and also by the experiment of causing two sperms to enter the same egg simultaneously, when it is found that the site of the dorsal lip of the blastopore lies on the meridian opposite that which bisects the angle subtended at the centre of the egg by the points of entry of the two sperms. This conclusion, arrived at with frogs, must, however, not be over-generalized, for it does not apply to sea-urchins. It is important to notice that polarity and bilateral symmetry, which are the prime differentiations in the egg of frogs and newts are induced by stimuli which act on the egg from outside. This means that the origin of differentiation is to be found in the reactions of the cytoplasm to external stimulation at a definite site. The origin of differentiation also coincides with the formation of an axial gradient of rate of protoplasmic activities, and the importance of this is that the qualitative nature of the tissue differentiated at any point is in

the first place determined by the relative quantitative rate of protoplasmic activities at that point. In other words, the prospective fate of a cell in normal development is determined by its position relatively to the axial gradients. This principle will now be further illustrated.

Axial Gradients and Differentiation.—When a piece is cut out of the body of a Planarian worm, the anterior cut end of the piece may regenerate a head, or a tail. That it should be capable of doing either is due to the fact that the nuclei all over the body are equivalent, and that the cells of such a lowly animal as Planaria are easily capable of reverting to an embryonic undifferentiated condition. Actually which structure will be formed depends on how much higher the rate of protoplasmic activities is in the cells of the anterior cut surface than in the rest of the piece. If the rate at the anterior cut surface is relatively sufficiently high, a head will form, and the degree of perfection of this head varies with the height of the rate. If the rate is too low, no head will be formed. The relative rates of protoplasmic activities can be controlled by means of certain substances (which have selective effects in increasing or depressing the activities of regions of high or low rate), and there is therefore experimental evidence that the quality of the tissue differentiated is determined by the relative quantitative rate of protoplasmic activities at the place in question. So it may be imagined that in the development of the egg, the axial gradients evoke qualitative differential responses from the cells according to the level of quantitative activity at which they are situated. Further examples will be given of the action of gradients in determining differentiation, but attention must now be turned to the nature of differentiation.

Plasticity and Determination.—Without being totipotent like the blastomeres of the 4-cell stage of the sea-urchin, cells may still show plasticity, in the sense that they are capable of differentiating into tissues other than those to which they would normally give rise. In the double-layered sac or gastrula, the outer layer is the ectoderm which will produce the epidermis and nervous system while the inner layer or endoderm will furnish the alimentary canal and its derivatives, like liver, lungs, etc. If a cap of cells be cut off from the animal hemisphere of the blastula of a sea-urchin, the remainder of the blastula cuts its loss and forms a gastrula smaller than normal (owing to the loss of tissue); and its inner layer or endoderm is reduced in size proportionately. This means that some of the cells which would normally have come to form part of the endoderm, actually become ectoderm; for the endoderm is in these animals formed by an inpushing from the surface of the blastula, and the proportionate reduction in size of the endoderm implies that fewer cells than normal are pushed in. That these cells should be capable of turning into ectoderm instead of into endoderm means that at the time when the operation was performed, they were not irrevocably determined. Identical results are obtained in newts up to an early stage of gastrulation, by experiments of transplanting pieces which would normally have become ectoderm, for instance ("presumptive" ectoderm), into other regions (*see* GRAFTING IN ANIMALS).

By transplanting between two different species of newts (heteroplastic transplantation), the cells of which differ as to their pigmentation, and in other respects, it is possible to identify the pieces of grafted tissue long after the operation, and to make certain of their actual fate. So, at this early stage in newts, a piece whose presumptive fate was ordinary epidermis, when transplanted to the appropriate region, actually became part of the brain and eye; and a piece of presumptive brain could be made to become part of the gills.

After a certain stage, however, these exchanges can no longer be made. If a cap of cells be cut off from the animal hemisphere of a gastrula of the sea-urchin, the endoderm remains of its normal size and is therefore out of proportion to the reduced ectoderm. The endoderm is therefore determined at this stage, and can no longer be converted into ectoderm. At the same time, within the endoderm itself determination has not yet taken place. The endoderm normally becomes divided into a number of regions bearing a certain proportion to one another. If at this gastrula stage when the endoderm cannot be turned into ectoderm, a piece of the endoderm be removed, the remainder will parcel itself out into the normal number of subdivisions in correct relative but reduced proportions. This illustrates the important fact that during development, determination takes place progressively.

Similarly in the newt, at a late stage of gastrulation, presumptive material shows when transplanted that it is determined. Presumptive eye material will differentiate into an eye even in abnormal positions such as the abdominal wall, facing inwards. Tissue which is "fixed" in this way is called self-differentiating. In the sea-urchin larva the mouth is self-differentiating, for it forms regardless of whether the alimentary canal is normally pushed-in or is experimentally everted (as in the so-called "exogastrula"). On the other hand, tissue which requires to be acted upon by neighbouring tissue in order to differentiate, is called dependent-differentiating.

Interesting examples of the effects which certain tissues exert upon certain others, can be obtained from tissue-culture experiments. Epithelium by itself, or connective tissue by itself, when grown *in vitro*, tends to lose its differentiation, and its cells revert to an embryonic condition. If, however, these tissues are cultured together, they maintain their differentiation; and if one of the two tissues dies, the other loses its differentiation. Use has been made of this property of inducing dependent differentiation in order to cause certain tissues to differentiate at will. Cultures of kidney-tissue of a mouse, or of a carcinomatous tumour of the mammary gland, grow as sheets of undifferentiated tissue *in vitro*. If some connective tissue is added to the cultures, the kidney-tissue redifferentiates its tubules, and the tumour gives rise to structures resembling those of a normal mammary gland. It is possible, therefore, that the contributory causes in tumour-formation may include not only an excessive amount of a growth-promoting substance (such as the autolysed extract mentioned above) but also the removal of the restraining influence on the part of other tissues, which normally produce and maintain a dependent-differentiated condition in the tissue which has become tumorous. Further examples of dependent differentiation will be mentioned below.

Chemo-differentiation.—In the newt and in the frog, the brain and spinal cord arise as a groove along the back, between a pair of so-called neural folds. The folds eventually meet over the groove, which thus becomes converted into a tube sunk beneath the surface. From the front end of this tube which is enlarged to form the brain, the eye-balls are pushed out to each side. If at an early stage, when the brain is still an open groove, a rectangular piece is cut out from it, rotated through 180°, and replaced, it continues its development by self-differentiation. In such a case, the anterior cut of the rectangular piece might pass through the eye-rudiments, and after rotation, portions of these eye-rudiments would find themselves transported back to abnormal regions. It is a fact that such operated embryos when they develop have not two eyes, but four, one pair behind the other, and of such a size that the sum of the sizes of all four is equal to the joint size of two normal eyes. This shows that the presumptive eye-rudiments were, although invisibly, yet nevertheless qualitatively and quantitatively, determined at the stage operated upon. A fixation of presumptive fate in this manner must be based on the presence of a definite amount of a chemical substance in the area which is determined. For this reason, determination of future organs may be called chemo-differentiation. The experiment just described is further interesting for two reasons. It shows by the variation of the constitution of the four eyes which are formed (which do not all possess the correct proportion between the sizes of the stalk, sensory layer and pigment layer), that not only is the eye determined as a whole, but that its constituent portions are also severally determined. The other point is that although the amount of determined tissue in any one of these four eyes is less than in a normal eye, nevertheless, it rounds itself off after the manner typical of an eye-ball. The same result can be obtained from other organs such as the nerve-cord itself, and it shows that the process of shaping the organ (or morphological differentiation) is distinct from the process of specialization of its constituent cells (or histological differentiation). The former is concerned with

conditions of available space and material and is the property of all the cells of the organ in general. The latter is the specific effect of chemo-differentiation on certain cells.

Organizers.—One region of the embryos of newts and frogs is peculiar, and that is the region of the dorsal lip of the blastopore. The tissue in this region becomes tucked-in beneath the superficial layer, and grows forwards beneath it, forming the roof of the enteron, or cavity of the gastrula. If a portion of this region be grafted into another position, it does not follow the differentiation of its surroundings nor does it simply pursue its normal prospective fate by self-differentiation, but it actually induces the cells which surround it, wherever it happens to be, to differentiate into the essential structures of an embryo. These structures are the nerve-cord, notochord, plates of muscle, kidney-tubes, eyes and ears. Since these structures lie along the axis of the body they are called the axial structures. The dorsal lip of the blastopore, therefore, has the power of organizing an embryo, for which reason it is called an organizer.

The organizer is that region which arises opposite the point of entry of the sperm, which is visibly differentiated as the grey crescent in the frog, and which an isolated blastomere must possess if it is to develop. The organizer is therefore an origin, and originator of differentiation, itself due to an external stimulus. With regard to its method of action, it is non-specific, for not only can organizers induce the formation of embryos in tissue of a different species, but even of a different order, as when the organizer of a toad works on tissue of a newt. Further, the quality of the tissue "organized" depends on the place from which the organizer was taken, and the level on the axial gradient of the other embryo (or "host") at which it is grafted. As new tissue is constantly turning over the edge of the dorsal lip of the blastopore and growing forwards, a piece of the organizer-region removed at an early stage of gastrulation would normally come to lie in the head, whereas pieces removed at later stages would lie in the trunk. A piece of head-organizer grafted into a host near the animal pole will organize a head, while a piece of trunk-organizer grafted into the host at a greater distance from the animal pole will organize a trunk.

Lastly, it is known that the property of organizing is not inherent in the cells of the organizer, but is something common to the region which they occupy. For if a piece of indifferent presumptive epidermis is grafted into the region of the organizer, and then cut out and grafted into a host, it will be found to function as an organizer. In other words, during its sojourn in the organizer-region, it has been infected with the capacity to organize.

The Eye and the Lens.—The eye-balls are, as already described, pushed out from the brain and subsequently become converted into the eye-cups. The lens fits into the rim of the cup, but it arises from a separate rudiment altogether, viz., the superficial epidermis. How, then, does it come about that the lens differentiates at the correct place so as to collaborate with the eye-cup in the formation of the perfect eye? This developmental correlation is of the greatest interest and importance. In the first place it was found that in the grass-frog (*Rana fusca*), the lens did not differentiate if the eye-cup was removed, and that any epidermis grafted over the eye-cup could be induced to differentiate into a lens, whether that was its presumptive fate or not. In other words, in *R. fusca*, the differentiation of the lens is dependent on that of the eye-cup which itself is dependent on the organizer. With regard to the lens, therefore, the eye-cup is a secondary organizer. The problem is however complicated by the fact that in the edible frog (*Rana esculenta*) the lens develops by self-differentiation when the eye-cup is removed (at the tail-bud stage), and not all esculenta epidermis can be induced to differentiate into a lens when grafted over the eye-cup. At the same time, the eye-cup has the power to organize a lens from suitable tissue, as is shown by the fact that it can do so from the epidermis of toads. *Rana esculenta*, therefore, has a self-differentiating lens, and at the same time its eye-cup is capable of organizing one; there is therefore what appears to be a "double assurance" that a lens will be formed. On the other hand, *Rana fusca* has a dependent-differentiating lens. The apparent contrast between the two methods of lens-formation in such closely related species is, here again, only a matter of time. The self-differentiating capacity of the lens of *Rana esculenta* only means that at the stage operated upon, the presumptive lens-rudiment had already been sufficiently chemo-differentiated to continue its development independently. At the operated stage, this condition had not yet been reached in the case of the lens-rudiment of *Rana fusca*. In almost all cases which have been sufficiently analysed, an organ which is self-differentiating at a particular stage is dependent-differentiating at an earlier stage. In the final analysis the chemo-differentiation of the various rudiments is referable to their position with regard to the gradient-system of the whole and to the organizer. In this way, in the frog and newt for instance, it may be imagined that the organism becomes mapped-out roughly into a number of eventually self-differentiating territories, and this has already been proved with regard to the nerve-cord, eye, lens, ear, nose, sense-organ placode, hypophysis, limb, liver, pancreas and heart.

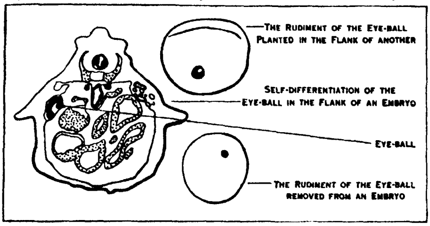
Once chemo-differentiated, these regions lose the power of differentiating into other regions, but within themselves, as in the case of the endoderm of the sea-urchin, they are still capable of regulation. So two limb-buds grafted together will regulate to form one normal limb, and the same applies to two heart-rudiments. The organism is progressively split up into smaller and smaller self-differentiating regions. This is well shown in the case of the limb-bud of a 4-day incubated chick. Each quarter of the limb-bud, when grown separately, differentiated independently, as a piece of a mosaic, to its presumptive fate.

The Periods of Development.—So far, in this account, it has been shown that differentiation originates in relation to axial gradients and organizers, until the organism is a collection of self-differentiating rudiments, developing without regard to one another and without co-ordination or correlation. It is important to notice that during this period, the organs and tissues differentiate without functioning, as is indeed obvious, for functions cannot be performed until a certain degree of differentiation has taken place. Nevertheless, this distinction is important, for in subsequent stages of development the further differentiation of the organs is conditioned by their functioning. The two periods may accordingly be called the non-functional and the functional periods of development respectively, and it is to Wilhelm Roux, the founder of modern experimental embryology, that the science is indebted for this distinction. Meanwhile, it must be noticed that during the earlier period of non-functional development, when the self-differentiating rudiments are pursuing their development independently of one another, regeneration and regulation is not possible. If the limb-bud rudiment is extirpated from a chick embryo during this period, the chick will always lack this limb. This matter has considerable philosophical interest, for it is common to find that regulation is regarded as a characteristic and fundamental phenomenon of living matter, and thereby distinguishing the latter from non-living matter. That regulation should not be of unfailing occurrence even among living things indicates that caution is necessary before adducing regulation as evidence for the exclusiveness of the nature of living processes. This is further shown by a study of the processes of regeneration, in which it is untrue to say that that which is regenerated is always that which was lost. It may be that too little is regenerated, or too much, or the quality of the regenerate may be entirely different from that of what was lost. Be this as it may, it is nevertheless true that regulation when it does occur is none the less interesting: a matter to which return will be made below. It is now time to turn to the second of Roux's periods of development.

Functional Differentiation.—The blood-vessels of the body are at first laid down roughly in certain definite positions and directions during the earlier period of non-functional self-differentiation. Their subsequent differentiation and the details of their connections with the tissues and one another take place during the later period of functional differentiation, and are governed actually by the functions which they perform in supplying the various tissues with blood according to their needs. The diameter of the vessels and the shaping of their bifurcations become adapted to the flow of blood so as to oppose the least resistance to it. The walls

of the vessels differentiate in accordance with the internal pressure of the blood which they have to withstand. So when a section of vein (which normally only has to deal with low pressures, and has a relatively feeble muscular wall) is transplanted into a position in the course of an artery (which has to withstand high pressures, and has a well-developed muscular wall), it becomes structurally converted into an artery, and its muscular wall becomes twice as thick. The definitive form of the blood-vessels is therefore the manifestation of their functional activity.

Tendons form the link between muscles and the bones to which they are attached. From their position it is obvious that they have



FROM "THE BRITISH JOURNAL OF EXPERIMENTAL BIOLOGY" (CAMBRIDGE UNIVERSITY PRESS)

FIG. 2.—SELF-DIFFERENTIATION OF THE EYE

to stand great tensions, and the fibres of connective tissue of which they are composed are arranged parallel to one another. The differentiation and parallel arrangement of these fibres is brought about by the pull which the muscle exerts at the end of them. This can be proved by cutting a tendon and allowing it to regenerate. Instead, however, of allowing the muscle to exert its pull on the fibres, the muscle can be cut out and a silk thread can be left in the track of the differentiating fibres. If this silk thread is pulled, the fibres of the tendon become orientated parallel to the line of this artificial tension. It is the function which they subserve, therefore, which is responsible for the differentiation and perfection of tendons.

The formation of bone presents a case not very dissimilar from that of tendons. Bone is not solid all through, but is composed of a large number of splinters and spicules, and the first appearance of these is a result of self-differentiation without function. The structure of a fully-formed bone, however, shows that the splinters are so arranged that they are in a position to withstand the maximum amount of pressure and tension to which the bone is normally exposed. It looks as if the differentiation of these splinters was determined by the incidence of these pressures and tensions. This must in fact be the case; for if a bone is broken and reset, the incidence of the pressures and tensions will be slightly altered, and it will be found that the old splinters of bone will be removed and replaced by others which answer more accurately to the functional requirements of the whole bone. To account for this, it is necessary to assume that there is a particular condition of pressure and tension which is most suitable for the differentiation of bone-splinters. That being so of a number of splinters lying in all directions, those which lie in the lines of pressure and tension will be favoured, while the others will be handicapped in their differentiation. This means that there is an internal struggle between the parts of an organism, some of which are preserved and others eliminated by a particular form of natural selection. The optimum conditions for which such a competition strives may not only be special functional situations, but also conditions of available space and nourishment.

The muscles of the body of a higher animal such as a dog may be of one of three kinds. There is the smooth muscle which forms the wall of the blood-vessels, the alimentary canal, and the bladder, and which is not subjected to any very violent or prolonged exertion. Then there is the musculature of the heart, which possesses a particular striated structure, and which is given to a perpetual and rhythmical life of contraction. Lastly there is the striped skeletal musculature of the body, which is under the control of the will, and which is capable of very violent effort, as in running upstairs for instance. Now, the function of the musculature of the wall of the bladder (of a dog) may be increased by connecting the bladder (by means of a cannula) with a tube leading from a jar containing a neutral fluid. In this way the amount of fluid in the bladder and the pressure at which it stands can be artificially, and precisely, increased. In this way the wall of the bladder can be made to expel more than a hundred times the normal amount of fluid per day, and it was found that the musculature took on the function of contracting rhythmically, and as often as two hundred times a minute. At the same time, the muscular wall of the bladder becomes very considerably thickened, and its cells differentiate into striated muscle-cells, similar to those of heart-muscle. These remarkable results are due to the effect of the function of expelling large quantities of fluid at high pressure. Other cases of functional differentiation are to be found when tadpoles are fed on herbivorous and carnivorous diets. To obtain the same amount of energy from animal and from vegetable food, it is necessary to eat much more of the latter, and consequently the alimentary canals and absorbtive digestive surfaces of herbivorous animals are as a rule larger than those of carnivores. Of the tadpoles treated with the two kinds of diets, it is actually found that the absorbtive area of the vegetarian tadpoles is twice that of their carnivorous brethren.

These cases of functional differentiation grade insensibly into those of the functionally adaptive effects of use and disuse. This can be particularly well illustrated by contrasting the muscular development of athletes and of persons who lead a more sedentary life. The nervous system itself, after a rough outlining of its rudiments by non-functional differentiation, becomes perfected with the help of function.

The Nervous System.—The functional differentiation of the nervous system is peculiar because of the particular nature of its function. Nerves are composed of fibres which are formed as outgrowths from the nerve-cells or neurons. Their development can be studied in tissue-cultures, and their formation is a self-differentiation. Other experiments have shown that the direction of the outgrowth of the fibres can be controlled at will by passing an electric current through the tissue culture. Now, one of the manifestations of the axial gradient is a difference in electric potential passing down the axis of the body. (The head-end is electro-negative in the external circuit relatively to other regions.) It must therefore be due to this electric gradient that the fibres in the brain and spinal cord grow down the cord and give rise to the fibre-tracts. Further, the tissue-culture experiments have shown that if a conductor carrying an electric current is led through the culture, the fibres grow out at right angles to the conductor. Returning to the nervous system, when a nervous impulse passes down a fibre, it may be compared with a conductor carrying an electric current. If, therefore, impulses pass down the fibres which run down the spinal cord, the neurons which are then differentiating will tend to grow their fibres out at right angles from the spinal cord. This is precisely what the motor nerve-roots of the spinal cord do.

The question now arises as to why the nerves connect up with their proper terminations. If a limb-bud of a newt is cut out and replaced a certain distance behind its normal site, the nerves which normally supply it grow out, and find the limb-bud in its abnormal position. There must therefore be some kind of chemical attraction which guides the nerves to their appropriate destinations.

The next problem to consider is why the brain and spinal cord develop special accumulations of nerve-cells exactly where they do, in relation to particular organs, such as the eyes or the limbs. The fibres running into the brain from the eyes end in the roof of the region known as the midbrain, where normally there is an accumulation of other nerve-cells which carry on the impulses elsewhere. If the eye be removed at an early stage, however, this accumulation of nerve-cells in the roof of the midbrain does not arise. Similarly, a frog deprived of its hind legs does not develop the hinder region of its brain properly. If an extra limb-bud is grafted on to the side of a newt, it is the sensory nerve-cells, but not the motor cells which are increased in number. Conversely, the motor nerve-cells in the limb-region of the spinal cord become

increased in number if an extra brain is grafted into the spinal cord in front of the limb-region. The sensory cells receive their impulses from the limbs, and the motor cells receive their impulses from the brain. The increase in number of nerve-cells in any special region of the nervous system is therefore governed by the number of nervous impulses which these cells receive. Here, again, function controls differentiation, and it becomes easy to see why animals which have certain senses particularly well developed also have enlargements of the corresponding regions of the nervous system. Lastly, there is the principle of neurobiotaxis, according to which a nerve-cell tends to move in the direction whence its habitual stimulation by nervous impulses comes. This principle accounts for the intricate internal disposition of the various centres of the nervous system.

Chemical Correlation.—The period of functional differentiation is essentially one of correlation of the various regions of the organism into one whole, and of an internal struggle between them. Some organs are on a footing of equality with others, others again are related by a system of dominance and subordination. The effects of such correlation can be well shown in the case of the sea-squirt *Perophora.* This animal is colonial, and the members of a colony are interconnected by a tube-like structure, the stolon, which is common to them all. If an individual with a portion of stolon is isolated in a glass vessel, the normal dominance of the individual over the stolon in the "struggle of the parts" asserts itself, and the latter may be absorbed by the former. In unfavourable circumstances, however, the balance may be upset against the individual and in favour of the stolon, which will then grow at the expense of the individual.

The correlation of the various parts of the organism is carried out by the nervous system and by the circulation of the internal body-fluid, the blood, which comes to be called the "internal environment." The importance of the blood as a correlating agent is based on the presence in it from time to time of chemical substances with specific effects (hormones) produced by special (endocrine) glands (or glands of internal secretion). During development, some of these hormones have very important effects. The pituitary produces a secretion which accelerates growth, while the reproductive organ's secretions in birds and mammals play an important part in the differentiation of the sexual characters. In frogs and newts, the thyroid gland is of particular interest and importance, because it is largely concerned in the conversion of the fish-like water-living tadpole into the land-living adult frog or newt. For the details of this phenomenon *see* METAMORPHOSIS.

External Factors.—In all the cases hitherto considered, the external environment of the developing embryo has been taken as normal and constant. It is, however, of the utmost importance to realize that external factors exert a control over development. Temperature is an important factor which affects the speed at which the chemical reactions which go on during development take place. The various reactions are not all affected by temperature to the same extent, so that a rise or fall of temperature may throw the developmental processes out of gear with one another. Sea-urchin embryos grown in a raised temperature, show the anomaly of everting the alimentary canal (forming so-called exogastrulae) instead of pushing it in.

Electric currents have been shown to affect the direction of outgrowth of nerve-fibres, and they also control the direction of development of the sea-weed *Fucus,* and the regeneration of the hydroid polyp *Obelia,* by inducing polarity in them. The chemical concentration of the surrounding medium has a very important effect on development. This can be shown in the case of marine forms, and either by adding certain chemical substances to the water, or by making up artificial sea-water identical with the normal except that it lacks some constituent. So, with regard to sea-urchins, it is found that chlorine is necessary, or no cleavage of the egg will take place. Calcium is also essential, for without it the blastomeres into which the egg cleaves do not remain together but become separated. Use of this fact is made in the experiments to determine the potencies of isolated blastomeres, which, after separation, continue their development. Addition of lithium to the water has the remarkable effect of suppressing the ectoderm of the gastrula at the expense of the endoderm. Potassium prevents the larva from developing the skeleton and arms of which they are typical. Perhaps the most remarkable effect of all is obtained after treating very young embryos of the fish *Fundulus* with solutions of magnesium chloride, chloroform, alcohol or ether. In these cases, instead of the fish developing the normal two eyes, there are varying degrees of fusion between them corresponding to the strengths of the solutions, until in the extreme cases, like the Cyclops of old, the fish have only one median eye.

The Relation Between Internal and External Factors During Development.—The case of eye-fusion or Cyclopia is of the greatest interest. It shows that fertilization, a proper store of food, and an organizer, are not the sole conditions necessary for the normal development and differentiation of the paired eyes so characteristic of vertebrates. These internal factors, and here must also be included the hereditary factors or Mendelian genes, are powerless to produce anything out of the fertilized egg if the external factors of the environment are not normal. This matter leads on to the consideration of the relative importance of internal and external factors in development, a question often put as the relative value of heredity and environment on the production of the individual.

In the first place, it must be noticed that although the fertilized egg contains a number of hereditary factors, yet, as development proceeds, these are not the only internal factors which the organism contains. The possession of the organizer in the newt's egg is an internal factor, but it cannot be said to be inherited, since its appearance is evoked by an external factor, the entrance of the sperm. (The presence of an organizer in eggs which have been stimulated to development by artificial parthenogenesis, and therefore without a sperm, must be due to the establishment of an axial gradient by other means.) New internal factors which were, as such, not inherited, are constantly arising during development, as a result of the interplay between the existing internal factors and the external factors.

There is another point to consider, and that is that while the hereditary factors (*see* GENE) govern the kinds of structures to which the embryo can by differentiation give rise, yet these hereditary factors cannot of themselves be held to account for the origin of such differentiations. This conclusion follows from the proof that nuclear division during cleavage is not qualitatively unequal, but that on the contrary, all the cells receive an equivalent outfit of hereditary factors. Further, there is the positive fact that the quality of the organs differentiated and their positions in the organism depend on their relations to the axial gradients of rate of protoplasmic activities, and these can be shown to be due to external factors acting on the embryo. Without an axial gradient a sea-urchin will not develop although it contains the complete set of hereditary factors.

The conclusions of the preceding paragraphs enable an answer to be given to the old question as to whether development takes place by Preformation or Epigenesis. Of the old crude notion of preformation in the sense of spatial invisible rearrangement, it is no longer necessary to speak. But it is not so easy to dismiss the hereditary material as a non-spatial predetermination. However, it has just been shown that the differentiations which the hereditary factors may be held to determine, do not arise if external factors have not previously evoked axial gradients. Further, the factors which are operative in the later stages of differentiation (especially the functional period) do not yet exist at the earlier stages. It follows, therefore, that development is a true creation of differentiation in each individual that develops; it is a response to the external factors made by the successive internal factors as and when they arise. As such, development partakes of the nature of an Epigenesis; the embryo is not preformed in the fertilized egg. The only proviso which it is necessary to make is that if the embryo is formed at all, the hereditary factors ensure that it belongs to the same species as its parents. In other words, the hereditary factors limit the possibilities of the response which the embryo can make to the external factors.

The connection between parents and embryo by means of the hereditary factors has been compared with a narrow bridge, across

which it is very difficult to see how the beautifully delicate adjustments of the fully-developed body can be conveyed. Such efforts of understanding can however be spared, because it has been shown that the adaptive perfection of the tendons, of the bones, of the blood-vessels, muscles and nervous system, are the result of functional differentiation. They are developments made independently and afresh by each individual of each generation, and the same applies to the relation between the lens and the eye. The correlations take place during ontogeny; they are not transmitted through phylogeny. The result of these considerations is to throw much of the burden of genetics (in the wide sense) off heredity and on to experimental embryology.

Regulation.—The reader of the foregoing account will already have noticed a number of cases of regulation. Isolated blastomeres of the sea-urchin and other forms, blastulae with part of the animal hemisphere cut off, will develop as reduced wholes instead of as incomplete parts. For this to be possible it is necessary that the embryo when operated upon should still be in a stage when the tissues are plastic, and before the cells have been irrevocably determined by chemo-differentiation. But the chief problem is: how can that which was a part acquire the properties of a whole, especially since it is immaterial what relation the part in question bore to the original whole? To Driesch, this question appeared to be unanswerable in terms of the physical categories of the universe, for which reason he abandoned the attempt to explain development in physico-chemical terms. He substituted a vitalistic system of "entelechies," which admittedly placed living processes in a category apart. Unfortunately, this procedure also has the effect of withdrawing the study of development from the possibility of attack and analysis by scientific, and therefore by mechanistic, method. The programme which modern experimental embryology follows, as laid down by its founder Wilhelm Roux, is the splitting up of the processes of development into simpler component processes, of which it may be said that such a result always follows from the action of such and such factors under given conditions. So it may be said that the organizer induces the differentiation of the axial structures in newts and frogs; that the eye-cup induces the differentiation of the lens in *Rana fusca;* that nerve-fibres react in a definite way to electric currents; that the multiplication of nerve-cells is a function of the number of nervous impulses which they receive; that axial gradients determine the place of and nature of differentiation of various organs, and so on. These components of development may not yet be simple enough to be analyzed by terms of physics and chemistry, but that does not matter. It is already a great step in advance to have a body of fact relating to the biological properties of certain tissues, as ascertained by their biological effects. In this way, experimental embryology or *"Entwicklungsmechanik"* (developmental mechanics) is becoming an exact science. Now, on turning to regulation, it becomes important to inquire whether a formal mechanistic explanation is possible, before relegating the problem to a position where it cannot be attacked. For this purpose, a few more cases of regulation will be considered.

The case of the blastula of the sea-urchin can be paralleled very closely in the development of the newt. If the ventral half of the blastula of a newt be removed, the dorsal half which contains the organizer will go on developing. When the neural folds arise in such an embryo, they are of the correct size relatively to the reduced size of the embryo; in other words, regulation has taken place. If the ventral half of the embryo is removed at a later stage however (during gastrulation), the neural folds when they appear are of the original normal size, and therefore quite disproportionate to the reduced size of the embryo.

Stylaria is a small worm, the head of which occupies the first five segments of the body. Behind the head are the crop and the oesophagus which occupy segments six to eight. If the body is cut across anywhere behind the head, five segments are regenerated from the anterior cut surface, and these undergo differentiation into a new regenerated head. But the alimentary canal of the next three segments, which were part of the ordinary trunk, becomes transformed into crop and oesophagus. This case forcibly suggests the action of axial gradients, which, passing back from the head, have certain relative levels (degrees of intensity of protoplasmic activities) at which tissues become qualitatively determined into crop and oesophagus.

The hydroid polyp *Tubularia* shows a comparable state of affairs. If the polyp is cut off, a new one forms beneath the cut surface without regeneration, by transformation *in situ* of the stem. The polyp contains four distinct zones, and these zones bear fixed proportions to one another as regards their width. But the whole reformed polyp bears a relation to the length of the whole piece of stem, and what is more, the size of the polyp can be controlled by external factors which are known to affect protoplasmic rates of activities, and therefore the axial gradients. These cases of regulation therefore suggest that axial gradients are somehow involved in the problem. Now reverting to the proposition to the effect that the fate of a cell is governed by its position with regard to the whole organism and to its axial gradients, it is only necessary to assume that the levels on the gradient at which particular differentiations are evoked, have a relative and not an absolute value, in order to arrive at a mechanistic formal explanation of regulation. Actually, this is no assumption, but a statement of fact, for there is considerable experimental evidence from the quality of regenerates of pieces of the worms *Planaria* and *Lumbriculus,* to show that it is relative rates of protoplasmic activities, or in other words the steepness of the axial gradient, which are responsible for the quality of the differentiation.

Lastly, it is necessary to guard against the danger of exaggerating the effects of regulation. Thus, the vegetative half of a gastrula of a sea-urchin is by itself capable of forming a little gastrula, but such a gastrula is deficient in that it possesses no mouth. This follows from the fact that the organ-forming substance for a mouth is already determined and restricted to the upper or animal portion of embryo from a very early stage. There is therefore a simple mechanistic explanation for the absence of a mouth in these operated embryos. But on the vitalistic theory of entelechies, it is inconceivable why the regulating principle, which is supposedly responsible for the perfection of the embryo, should fail in this respect.

EXPERIMENTAL PSYCHOLOGY is a method of studying psychological problems and is not to be regarded as itself constituting separate subject-matter. It is a systematic attempt to determine the conditions of animal and human conduct by the arrangement and variation of typical situations in response to which such conduct normally occurs. Like every other science it is thus primarily concerned with the discovery of causal laws operating within the field of its study. Experimental psychology does not, so long as it keeps within its proper limits, speculate as to the exact nature of the materials with the relation of which to their stimuli it is directly concerned—that is, with sensations, images, ideas, judgments, trains of reasoning, feelings, emotions, sentiments, impulses, volitions—but it does set out to find the conditions for the occurrence of all of these, and to explain how, when they have occurred, they may themselves operate as conditions of subsequent conduct. Moreover, the experimental psychologist professes to deal with conduct as it occurs in the intact organism, and the implications of this are now coming to be much more completely realized than was the case a few years ago. Many of his problems appear to be similar to those of the physiologist. Both alike, for example, study the conditions of visual and auditory reactions. But the physiologist is largely concerned directly with the reactions of the special sensory apparatus involved. Whenever possible he can legitimately isolate this and consider what occurs within it when various stimuli are being brought to bear upon it as giving an answer to his questions. The experimental psychologist is concerned with the reaction to similar

INSTRUMENTS IN THE PSYCHOLOGICAL LABORATORY OF THE UNIVERSITY OF CAMBRIDGE

1. Corner of a modern psychological laboratory. On small table, middle foreground, McDougall dotting apparatus, for experiments on attention and mental fatigue; right forground, Hipp's Chronoscope (*see* figure 3); left centre, Krapelin's Ergograph for measuring muscular fatigue; right centre, "Psychogalvanometer" for experiments on emotion; left background, on high stand, Müller memory apparatus
2. Colour wheels which rotate rapidly, to show the effects of mixing colours of varied hues, and to demonstrate the effect of one colour upon another simultaneously exposed in a neighbouring field
3. The Hipp Chronoscope, developed from an instrument first made by Wheatstone in 1840, and used to measure human reaction to given signals. The dial hands operated by an electro-magnetic mechanism may be started when a prearranged signal is given and stopped when the reaction is observed. The time of the response is measured in thousandths of a second
4. A Choice reaction apparatus, which measures speed of reaction when any one of a number of signals occurs and the observer does not know beforehand which one is coming. The timing instrument is an electrically controlled hundredth-second stop-watch over the box; the stimuli may be lights of different colours or a sound. There are five Morse keys, one for each signal produced on the opposite side of the box
5. An instrument used by experimental psychologists for any purpose involving the production of series or groups of momentary stimuli. The appropriate grouping is secured by putting in circuit with the instrument telephones, electric lamps or other apparatus to produce whatever electrically controlled stimuli are being employed
6. Corner of a research room in a modern experimental psychological laboratory. The apparatus illustrated is part of an instrumental setting for investigating phenomena in the localisation of sounds

stimuli, not, for instance, of the eye alone, but of the visual mechanism in its intimate relations to the conduct of the rest of the organism. Naturally this renders his problems very much more complex and his solutions at present have to be expressed more tentatively, more contingently.

Sources.—Experimental psychology as a systematic study grew out of the work of physicists and physiologists who were compelled to recognize the important part played by the human observer in the results which they obtained from their experiments. Thus it was at first almost entirely concerned with the measurement of "reaction-times"—*i.e.*, the time elapsing between the giving of a stimulus and the making of a prescribed response by the observer—and with a study of the special senses. In a brief survey, it is impossible even to mention the names of many pioneers whose work gradually developed modern methods of experiment in psychology. A very great amount was due to Gustav Theodor Fechner, however, who, appointed professor of physics at Leipzig in 1834, elaborately endeavoured to obtain exact quantitative statements of the relation between the intensity of a stimulus and of the sensation which it evokes. His reasoning has never commanded wide assent, but the actual methods of observation which he initiated have been developed in many ways and are the foundation of a large part of modern experimental procedure. In 1885 Hermann Ebbinghaus published the results of a long series of experiments which he had made upon himself in the memorizing of nonsense syllables. He claimed that the use of this kind of material made it possible for the first time to experiment successfully on the "higher mental processes." Although, as in the case of Fechner, there is reason for doubting the validity of many of his claims, his work undoubtedly inspired a large quantity of further research. Near the beginning of the present century Oswald Külpe took a further step by encouraging a number of researches upon judgment and volition, while throughout the whole period, from Fechner onwards, experimental work on feelings and on certain specific psychophysical problems, such as that of fatigue, have been continued. In England the approach to experimental work in psychology has been, from the time of Francis Galton, in general by a biological route. The importance of statistics as a method of dealing with experimental results has received special attention and in many ways experimental psychology has been closely in touch with neurology and medicine.

It is curious that the genuine experimental study of animal behaviour is a very recent growth. With a few exceptions, and those for the most part due to the interest of comparative anatomists in the localization of various bodily functions, the anecdotal method of Aristotle remained predominant in the study of animals till the present day. That there is now a flourishing school for the experimental study of animal behaviour is due in the main to America and in particular to Edward L. Thorndike, Robert Yerkes and John B. Watson.

The Present Status of Experimental Psychology.—There is now no important university anywhere in the modern world but in some way recognizes the right of experimental method in psychology to a position in the scheme of higher education and of scientific research. Most of the leading universities, at least in America, Great Britain, Holland, Germany, France, in most of the British colonies and, to a rapidly increasing extent in Russia, China and Japan, provide actual experimental laboratories, though there is still room for much improvement in this respect. A considerable number of well-established journals exist for the publication of the results of experimental research in psychology. Apart from university teaching there are, in almost every vigorous modern nation, flourishing organizations for the practical application of psychology in various directions, particularly those of education and industry. There is a rapidly growing recognition of the importance of psychological teaching and research in relation to the practice of medicine and law and to the organization of a country's defensive and offensive services. It would be easy to show that the development of this practical aspect of psychology has been made possible directly and almost entirely by the use of experimental methods.

The Psychological Laboratory.—It is still true to say, however, that the majority of people who are interested in psychology in a general way have never seen the inside of a psychological laboratory and are somewhat puzzled to think what problems the experimental psychologist investigates and how he proceeds. In the accompanying plate are reproduced photographs of some of the apparatus which experimental psychologists frequently use. Only a very small selection can be reproduced in this way, however, and it will therefore be of interest to describe certain typical equipment and methods as they are to be found, or as they are employed in any modern laboratory devoted to psychological work.

As has been stated already the earliest experimental psychologists were physicists and physiologists and consequently a great amount of work in the psychological laboratory is concerned with the special senses of touch, temperature, taste, smell, vision, hearing and movement. Let us select two groups of these, for a somewhat more careful description: those dealing with visual and those dealing with auditory reactions. Here, then, are colour wheels on which discs of different colours may be rotated so rapidly that the resulting sensations combine and the effects of mixing colours in varying proportion can be accurately determined. Special apparatus demonstrates the after effects of continued light and colour stimulation, and the occurrence of colour blind or colour weak zones in the normal eye. A dark room is provided designed to show clearly the differences between vision in daylight and in twilight and to bring out some of the theoretically and practically important facts connected with abnormalities of colour vision and with night blindness. All of these may be seen in the physics laboratory or in the physiological laboratory. But the psychologist now realizes that his main problems and his methods of approach are his own. The physicist is chiefly concerned with an analysis of the stimulus, the physiologist with the mode of reaction of the eye itself, for instance, and with its connections with the central nervous system. The psychologist must be concerned with these also but has all the time to keep clearly in view how the accuracy of the observations themselves is determined. Thus he has to be particularly careful to study the effects of the method and order of presentation of the stimuli. He knows that these and numerous other factors, some of which may be extraneous to the particular experiment involved, determine the observer's *attitude* towards what is set before him, and that this general *attitude* for which there is no obvious or immediately available physical or physiological expression, in turn may powerfully influence his observations.

With the same aim the psychologist carries out experiments on sound. He notices a man's normal reactions to sounds of different pitch, intensity and complexity, studies the results of combining tones in various ways, measures the acuteness of an observer's reaction to sounds of given character, and demonstrates how the ears make it possible to judge where a sound has its source. He shows how all these apparently simple responses are in reality exceedingly complex and how an important part of their conditions often has to be stated in terms of what are called the "higher mental processes."

But obviously the world in which men live is not mainly a world of shifting patches of light and shade, of colour, of isolated sounds, tastes, smells and similar sensory characters. It is a world of *things* identified, named, referred to some position in space, or apprehended as moving in some direction. So the experimental psychologist must try to show the conditions, not only of the relatively abstract sensory response, but of the more concrete perceptual processes that men are constantly carrying out. He has apparatus for the controlled exposure of objects: stereoscopes and devices for the study of the perception of solidity or of distance, and of the various optical illusions; means by which he can demonstrate how sensations of differing kinds may all come together into a single complex perception.

A very little study of these perceptual processes is enough to demonstrate that in many instances what is actually perceived at the moment is only a little of what a person reports that he has observed. We fill up the gaps of perceptual data by using images, or relying upon recollection, in some form, of past events,

as when a person, travelling at high speed in an express train sees only parts of things through the carriage window and then reports his observations with much more detail than could possibly have been discriminated at the time. Considering this the experimental psychologist is led to arrange special situations with a view to the production of mental imagery and to study the types and functions of the imagery produced. Once more employing his exposure apparatus, so that the conditions of reaction can be at least partially controlled, he presents common objects incomplete in some respects, or material arranged in a series which gradually approaches a climax, or material directly designed to produce ambiguous or alternating reactions, or material conflicting with some other simultaneously presented perceptual data, and in these and other ways seeks to arouse mental imagery and so to discover what functions it fulfils.

It is now but a little step to the study of memory proper. Here a vast field of research, with its own peculiar technique in the construction and presentation of material to be memorized, is opened up. The experimenter has to investigate economical methods of learning, rates of forgetting, the influence of specific factors such as position in a series upon immediate and remote recall, and to try to measure association strengths between items presented simultaneously or in succession. For all this he has his specially devised material, his specially arranged methods and his specially constructed apparatus.

Throughout the whole range of psychological experiment an observer frequently has to judge, to choose, to decide, and often reports that his reaction processes are accompanied by feelings and emotions. How can these functions of judging, choosing, deciding and feeling be themselves experimented upon? As regards the first three of them the essential method is to place an observer in some situation which sets him an interesting problem. The solution has to be effected by judgment, choice or decision. Thereupon the experimentalist brings into play apparatus by which he can record some of the physiological changes which accompany these mental processes, such as variations in respiration, in pulse rate, or in glandular secretion. At the same time the observer, acting throughout under relatively controlled conditions, gives a verbal report of the processes which seem to him to have led up to the judgment, or the choice, or the volition. The problem situations may be indefinitely varied in complexity, from the simple judgment as to which of two weights is the heavier to decisions upon controversial questions of great difficulty. In regard to feeling also some exciting stimulus or situation is presented, and the observer reports verbally the factors which appear to induce his feeling, while changes of respiration, of pulse beat, of glandular secretion, of resistance to the passing through the observer's body of an electric current and so on, are recorded.

As a part of practically all of the general fields of investigation already mentioned it is often of interest to measure the speed at which the combination of physical, physiological and psychological processes involved takes place. For this purpose the psychologist has developed elaborate and delicate "reaction-time" apparatus by which he can determine, up to a thousandth of a second, the time elapsing between the occurrence of a stimulus and the response to that stimulus in some pre-arranged manner.

Especially interesting questions arise in the investigation of abnormal conditions. What, for instance, are the effects of glare, or of flicker in the visual field; of excessive and continued noise or vibration in the auditory and tactual fields; of drugs and fatigue upon psychical processes generally? The study of muscular and mental fatigue in particular has developed a mass of special apparatus and methods of research and has an immediate practical application.

In nearly all cases of psychological experiment very little reliance can be placed upon single and isolated observations. The conditions involved are always complex, always only partially controlled. Repeated observations are necessary. If these are to be successfully interpreted the experimentalist must be well acquainted with the technique of the "psychophysical methods," and he must have some knowledge of statistical theory and practice.

The experimental psychologist has no lack of problems with which to concern himself. In all the directions mentioned and in many others the application of experimental method is as yet in its infancy. The greatest success has so far been won in the realm of the study of the special senses and of perception. But his methods and results are now extending rapidly. More and more the higher mental processes are coming within the experimentalist's purview, so far as knowledge and control of their conditions are concerned.

In one direction in particular it is highly probable that the near future may see important advances. A great many of the conditions of our conduct are directly social in character and source. There has been little attempt to observe these under experimental conditions, but the task is by no means hopeless. We can so arrange experiments as to be able to observe at least some of the effects of socially derived motives: competition, pugnacity, assertiveness, submissiveness, friendliness, liability to suggestion and the like. The results obtained in this way must inevitably react upon the experimentalist's study of the individual, forcing him to investigate not only the operations of the intellectual, cognitive mechanism, but also the extremely important play of temperament and character. In some ways the most striking achievement of the experimental psychologist in recent years has been the development of exact methods of studying and ranking "intelligence." These may well be supplemented in the near future by more exact methods for the study of the social determination of conduct and the influence of individual temperament.

The Contemporary Situation.—A considerable change has come over experimental psychology since its early days. Then the chief aim was to render a description of certain experiences as they were experimentally produced and controlled. On the one hand the interpretation of the results obtained was dominated by theories taken over from general psychology according to which all complex experiences were regarded as made up of unitary elements of a sensory order which had been built together in the course of individual life by the "principles of association." On the other hand the actual methods employed were, as nearly as possible, copied from other experimental fields. Particular forms or varieties of experience, whether of a sensory, or of a "higher" order were, as far as possible, cut off from other kinds and correlated with their immediate physical stimulus. The result was often artificial in the extreme and experimental psychologists were constantly doing or initiating work which could be done much better by physiologists, with their specific training in the technique of the study of relatively isolated bodily activities. The view that complex experiences and reactions are genuinely aggregations of simpler forms has now practically disappeared. In consequence the problems of the experimental psychological laboratory have been brought very much nearer those of real life and, as has been indicated already, the experimental psychologist has developed a technique and a point of view which are as distinctive as they are effective.

A very powerful influence in bringing about this change has been the movement known as "Behaviourism" (*q.v.*). Men have always been interested in the study of the behaviour of animals. But until very recently their interest led them either to the descriptive type of study attempted by the field naturalist, or to the collection of remarkable animal stories interpreted in the light of human conscious experience. The development of an experimental approach to biology made "behaviourism" possible. At first, as in the field of general human psychology, experiments were mainly concerned with the special senses, and in particular with an anatomical study of the parts of the central nervous system in which various special sensory reactions, of sound, vision, taste, balance and the like may appear to be localized. Then experimenters began to try to observe exactly how various species of animals learn to discriminate one object from another, or to run successfully more or less complicated pathways in a maze. They decided to avoid explaining animal conduct in terms of human experience, and to limit themselves strictly to relating the conditions of their experiments, as any competent observer would describe them, to the conduct of the animals, as that, again, could

be described by any instructed on-looker. It seemed possible to do a great amount, and perhaps the whole of this without once using the notion of consciousness as a causal factor, for these experimenters rightly held that to attribute consciousness to an animal is to go beyond directly observable fact. Their success led them to put forward an exactly similar programme for experimental work in general human psychology.

Most experimentalists in psychology, however, still maintain their right to include in the conditions of the reactions which they study many that are, certainly for the present and it may be forever, incapable of being expressed in physiological terms. Many attempt to hold themselves free from any systematic theory about the nature of human experience and, taking up certain specific problems of reaction in human beings, insist that such reactions must be regarded as part determined by "attitudes," both conscious and unconscious, by "tendencies" whether instinctive or of a higher level, and by the accumulation of the results of past experience which appear or which function in the form of images, ideas, sentiments and so on. For example, much work is still being done on the minimal intensity of stimuli of varying quality which will produce a reaction. The experimental psychologist shows that these "threshold values" of stimuli of all kinds can be shown to depend in part upon "attitudes," images and like factors occurring during the course of the experimental investigation. He holds that, independently of any discussion as to their ultimate character, it is impossible at present to reduce these to physiological and much less to physico-chemical terms. Such a view being admitted experimental laboratories are to-day investigating problems over the whole field of human response. There is a revived interest, due largely to certain important practical difficulties which arose during the World War, in the psychology of the special senses, particularly those of vision and hearing. The image processes and their relation to perceptual reactions are the subject of constant experimental study. Memory is being investigated, less as an isolated type of response, and more as falling into place in a whole complex learning-process which may continually involve also the higher mental activities of judging, choosing, reasoning and the like. On the side of feeling and emotion increased interest in experiment has grown out of recent work on the effects of the secretions of endocrine glands. Methods of registering emotional expression through metabolic change are being further developed, and both in this field and in that of volition some psychologists expect much from the use of the galvanometer which appears to be capable of being used to indicate when certain changes commonly called mental take place.

In general the evidence seems to be going against strict behaviourism as a tenable theory. Towards this conclusion the experimental researches of the *Gestalt* school, as it is often called, have greatly contributed. Professor Max Wertheimer, followed by Professors Wolfgang Köhler and Kurt Koffka and many others, starting from some striking experiments on the way in which the perception of movement may be produced, have urged that it is impossible to consider the phenomena of perception as in any way made up of a number of isolable elements whether of sensory or of any other origin. We perceive "forms," "shapes," "configurations," which are doubtless complex, but whose character considered *as a whole* gives them their properties and their functions. The theory has been worked out most fully in the realms of visual and auditory perception, but as applied to problems of conduct it is clearly diametrically opposed to an interpretation which treats complex behaviour as the expression of numerous simple and relatively self-contained reflexes. The view that all high-level forms of activity possess characteristics of their own, in no way theoretically deducible from a study of the simpler conduct out of which they have undoubtedly developed is also in line with a mass of research of a more physiological and neurological order.

In whatever realm and with whatever general background of theory he works, however, the modern experimental psychologist is definitely committed to a biological method of approach. He regards mental processes as falling into their place in a biological adaptation of the organism to its environment, and his problems are thus becoming more and more an enquiry into the *functions* which such processes carry out, and less and less a mere description or a mere analysis of the processes themselves.

Modern Practical Applications.—A very few remarks may be added concerning current practical applications of experimental method. The application of experimental psychology to the solution of practical problems was strongly stimulated by the World War. During that period of time every important belligerent country called upon its psychologists for advice in the development, organization and training of its offensive and defensive forces. Much of the work then done continued and has been developed in many different ways. In industry psychologists have their special tests for vocational aptitudes and their methods of vocational guidance and training. The regulation of bodily movements, organization against "fatigue," and the study of accident liability have direct application both to the fighting services and to many departments of industrial work. In education the "intelligence test" movement has grown to enormous dimensions. In medicine the study of abnormal conduct and its explanation both by organic lesion and by functional disability for which no satisfactory organic lesion can readily be found have been rendered easier and more definite by the union of experimental method with clinical observation. In legal practice psychological experiments have been tentatively proposed and used in connection with the detection of crime.

The whole of this practical development has reacted powerfully upon those methods of academic research without which it could itself never have grown to importance. In this way also the laboratory has been brought nearer to the problems of real life, and the very great possibilities of experiment as contributing to a more complete understanding of man's multifarious activities is being explored with greater eagerness than ever before.

BIBLIOGRAPHY.—The best way of appreciating the nature and extent of experimental work in psychology is to consult the leading journals which are devoted to the subject. A list of the more important of these is included. C. S. Myers and F. C. Bartlett, *Text-Book of Experimental Psychology*, 3rd ed., parts 1 and 2 (1925, bibl.); J. Drever and M. Collins, *Experimental Psychology* (1926, bibl.) and *A First Laboratory Guide in Psychology* (1926); E. B. Titchener, *Experimental Psychology*, 4 parts (1925); H. Piéron, *Psychologie Expérimentale* (1927); R. Pauli, *Psychologisches Practikum*, 3rd. ed. (1923, Bibl.). Angewandte Psychologie* (Leipzig); *Z. f. Psychologie* (Leipzig); *Z. f. Sinnespsychologie* (Leipzig); *Psychologische Forschung* (Leipzig); *Archiv f.d. Gesamte Psychologie* (Leipzig). *See* also articles on ABILITIES, FEELING, INTELLIGENCE TESTS, MEMORY. (F. C. BA.)

EXPERT, strictly, skilled, or one who has special knowledge; as used in law, an expert is a person, selected by a court, or adduced by a party to a cause, to give his opinion on some point in issue with which he is peculiarly conversant. These are to be distinguished from the many experts, popularly so called who do not pass any recognized standard. In ordinary practice, the expert commonly met with gives evidence on technical matters not within common knowledge, *e.g.*, handwriting, medical and other sciences, engineering, valuation, etc.

There is some evidence that in England the courts were in early times in the habit of summoning to their assistance, apparently as assessors, persons specially qualified to advise upon any scientific or technical question that required to be determined. (*Year Book*, 21 Hen. VII., pl. 30, p. 33.) The practice of calling in expert assistance in judicial inquiries was not confined to medico-legal cases (*Buckley* v. *Rice Thomas*, 1554, Plowden, 124 a).

Foreign law can only be proved in English courts,—and the same rule applies in Scotland,—(*a*) by obtaining an opinion on the subject from a superior court of the country whose laws are in dispute under the Foreign Law Ascertainment Act 1861 or the British Law Ascertainment Act 1859, or (*b*) by the evidence of a lawyer of the country whose law is in question, or who has studied it *in that country*, or of an official whose position requires, and therefore presumes, a sufficient knowledge of that law (*Perlak, etc.*, v. *Deen*, 1924, 1 K.B. 111).

Statutory provision has been made in England for the summoning of expert assistance by the legal tribunals in various cases.

In France, whenever the court considers that a report by experts is necessary, it is ordered by a judgment clearly setting forth the objects of the *expertise* (Code Proc. Civ. tit. xiv.).

Experts in the United States stand in substantially the same position in the Federal and state courts as in England.

EXPLANATION. What is meant by explaining a phenomenon? There is no need to insist on the importance of this question. It is obvious that the entire structure of science will necessarily depend upon the reply given. The usual answer is that explanation consists in showing that a phenomenon obeys a law. This is the formula apparently first enunciated by Berkeley: *Nam inventis semel naturae legibus, deinceps monstrandum est philosopho, ex constanti harum legum observatione, hoc est, ex iis principiis, phaenomenon quodvis necessario consequi: id quod est phaenomena explicare et solvere, causamque, id est rationem cur fiant, assignare.* As is well known, Comte based his "Positivism" on this principle: Science seeks nothing but laws and, once these are discovered, science remains simply a collection of them. Whatever is not law is vain or, at most, provisional scaffolding,—for what science really aims at is simply preparation for action:—"Science, whence prevision; prevision, whence action." This is almost a translation of Hobbes's statement: *Scientia propter potentiam . . . omnis denique speculatio actionis vel operis alicuius gratia instituta est.*

Berkeley, as we have just seen, identified cause and law. Comte, on the contrary, saw that it is possible to investigate the cause of a phenomenon *after* having determined its law. But he severely forbade research of this kind. In his view, "only men absolutely devoid of the scientific spirit" are inclined to adopt such a procedure.

This way of conceiving scientific explanation is quite in accordance with the etymological meaning of the term if we remember that this implies merely that what was not entirely "level" has now been made so. From the same order of ideas is derived the German expression, *erklären*, "to make clear," so that what was hidden may become visible. All this seems in harmony with the positivist view that to explain a phenomenon is to describe it.

The term "explanation" however has, for its synonym, *explication* (in French this latter alone has been retained), while, in Latin, *explicare* originally meant "to unroll," and is almost synonymous with *evolvere* (whence the modern concept "evolution"). Thinkers of the Middle Ages often gave this interpretation to it, and among moderns, Hegel, Wallace and Ward have followed them. So understood explanation appears to be something quite different from description; it implies the preformation of the consequent in the antecedent. A phenomenon will be explained only when it is shown that what is new, what is surprising in it, should not have surprised us, since it was already present in a disguised form. And it is precisely in this element of wonder and certainly not in the desire to prepare for action, that Plato and Aristotle saw the true motive force of science.

Might this, however, not be a vicious, chimerical form of the search for knowledge? Might not the orientation of present day science in fact run counter to that of the past (tainted according to Comte with the "metaphysical spirit"), in conformity with the positivist scheme? This is a question which cannot be settled without an investigation of science itself.

Positivism.—It is to be noted, in the first place, that the search for causes, as distinct from that of laws, has been quite general in modern science; it is enough to think of gravitation to be convinced of it. Newton had determined its *law* (the accuracy of which had hardly been questioned before Einstein); but physicists declared themselves far from satisfied with the result, and continued to seek the *cause* of the phenomenon. Hundreds of theories, each more hazardous than the other, were suggested; and Maxwell (certainly one of the most genuine representatives of the purest scientific spirit in our age), far from condemning these efforts, has, on the contrary, expressly declared that a scientific theory which could lead to an explanation of gravitation would be sufficient inducement for scientists to devote the rest of their lives to it. But it would be difficult to define what they would be seeking if the law suffices to explain the phenomenon.

One must remember besides, that, as against Comte's formula, the dominant rôle in science is played not by law, but by causal hypotheses. Now, at bottom, the very existence of such theories is embarrassing for strict Positivism. Comte himself felt it and vacillated a little on their account, sometimes ruling them out entirely, at other times admitting them as a kind of provisional make-shift. Impelled by a strong scientific instinct, he even went so far as to declare the atomic theory "a good hypothesis."

But Mach, who built his theory of science upon a basis completely analogous to that of Comte, was more logical, for he violently opposed the revival of atomistic conceptions since the end of the 19th century, declaring (during a well-known controversy with Planck) that if physicists affirmed the reality of atoms to constitute an essential point of their scientific *credo*, he (Mach) would cease to think as a physicist and would forego their approval of his work. The majority of positivists, however, maintain a less uncompromising attitude. They admit causal hypotheses, hoping that subsequent progress in knowledge will eliminate them and reduce science to a system of laws entirely freed from hypotheses. Now, it is sufficient to consider the actual evolution of knowledge to convince oneself how little its progress corresponds to these views. Never has a mechanistic hypothesis disappeared before a simple law; like the priest of Nemi, it always had to be annihilated by some other theory that succeeded it. This fact seems sufficient to overthrow the positivist scheme.

Finally, there is observable in science the existence of a series of propositions (the most important, or, at any rate, the most general throughout the whole domain of our knowledge) the nature of which is ill determined, namely, the principles of conservation. Some thinkers have taken them to be simple empirical statements, while others have declared them to be *a priori*. But on a rather closer examination of these two opinions, it will be easily seen that neither has any solid foundation, and one wonders therefore how these principles met with such ready acceptance at the time they were proposed, and how they came to occupy such a high place in the hierarchy of dominant scientific truths.

So the positivist scheme is incapable of embracing the whole of science; it is quite vain to try to adjust the whole of science to this bed of Procrustes. What the positivist formula defines is only a part of science, the knowledge of laws; and if this part be subtracted from the total (an operation which Comte's formula enables us to do—and in this lies his great merit), there remains, so to speak, a residue. To use another image, the positivist key does indeed open many of the doors of science but not all of them;—there still remains a whole series of locks which it does not fit.

Preformation.—Now, it is possible to show that one new key, and only one, fits all these locks, namely, that of Preformation, referred to already. Statements about conservation, taken in the most general sense, affirm that despite apparent changes observed in the "real," something—velocity, mass, energy—remains invariable; atomism, or universal mechanism, proves on careful examination rather to be an explanation of change by displacement; and lastly, the search for the cause of gravitation (after its law had been determined) appears to be prompted in the main by mechanistic theories, and so is simply a case of the same procedure.

Is the solution which we have just reached quite complete? On examination, the concept of cause is found to involve motions to which the solution does not seem directly applicable. First, there is the fact that we demand the cause not only of that which changes, but also of that which persists. Aristotle himself sometimes spoke of "cause" in such cases, and Leibniz declared that if it were proved that the ultimate particles of matter were spherical, we still should ask why they were not cubical. Would this tendency be entirely alien to the nature of physics? It is easy to realize, on the contrary, that it exerts the most powerful influence

upon it. On this tendency depends an essential idea of mechanism, namely, the unity of matter, which it has not ceased to proclaim from the time of Leucippus and Democritus up to our own day; also another equally characteristic idea, viz., that this matter, of which all "reality" is made, has no quality except that of occupying space, and is therefore identical with *empty* space. Descartes, who may be called the codifier of modern science, boldly proclaims this identification, although he expresses it in a rather different way. He declares that there is no space where there is no matter; but one realizes through his very deduction that this "matter," having only geometrical qualities, is, at bottom, nothing but space.

In modern physics (or more precisely, before the appearance of Einstein's "general relativity") this reduction was carried out by a more round-about route; a semi-material medium, the ether, was postulated, and it was sought to explain material particles by such peculiar properties of this medium as rings, vortices, etc. It was understood, however, that this ether must possess no "occult quality," and this requirement obviously ended by making it identical with empty space, as Maxwell recognized, or else a simple hypostasis of space, according to Helmholtz. The relativists, in this respect, resumed the Cartesian tradition by abandoning to a greater or less degree the hypothesis of an ether.

Paradoxes.—A very thorough scrutiny is hardly necessary in order to see that this train of thought leads to an exceedingly paradoxical conclusion. For space (at least, the three-dimensional space of the pre-relativists) is evidently not susceptible of any change, and even if we suppose it filled with some quasi-material substance everywhere identical with itself (such as the hypothetical ether), movement becomes impossible, for its successive states cannot be distinguished one from another, "even by an angel," as Leibniz declared. Therefore, the outcome of all this labour of reduction, if by some miracle it might be brought to a successful conclusion, would be tantamount to reducing the real to nothing, to absolute annihilation. And we are driven to the conclusion that such aims, so paradoxical, so contrary to that which the physicist firmly believes to constitute his nearest and surest aim, namely, the understanding of the real, can only derive from a tendency rooted in the deepest part of the human mind—the *intellectus ipse*, whose existence is affirmed by Leibniz when to the scholastic formula, *Nihil est in intellectu quod non fuerit prius in sensu*, he adds the words *nisi intellectus ipse*. It will also be seen how far this tendency to discover the cause of the diversity among the co-existent is connected with that which attacks the diversity of the changing. The solutions, further, resemble each other. A moment ago we explained change, by showing it to be merely apparent, and so concealing a basic identity. Now we endeavour to establish that the "real," whatever be the matter which seems to fill it, is everywhere identical with itself. Explanation is accomplished, then, in both cases, by the help of what has been called the *principle of identity*, but which might have been better named the *schema of identification*. Hegel, indeed, has justly pointed out that the formula of strict identity A=A, constitutes a tautology pure and simple and, therefore, cannot serve as an instrument for any progress in thought. In reality, the second A is always regarded as differing from the first in some respect, and the work of the mind consists in establishing, or at least affirming, identity in spite of this difference.

Free Will.—Again, it is maintained, on the other hand, that the term "cause" is sometimes employed in cases where this concept of the identity of the antecedent and the consequent seems to be precluded from the outset, since their diversity is expressly affirmed, *e.g.*, when the reference is to an act of human or divine free-will. We are not here concerned to affirm or deny the existence of a free will; it is certain that we have the immediate sensation that our volition is the cause of our movements and that, for believers, acts of Divine volition cause phenomena. This causality may be called *theological*, in distinction from the "identifying causality" which is properly *scientific*. For while it would be an error to assert that science denies miracles, it is nevertheless true that it excludes them from its realm, just as it excludes human free will. Science does not limit itself to prevision but begins with it: whatever eludes prevision therefore cannot belong to scientific research.

The Irrational.—Since reason seeks identity, whatever opposes its efforts in this procedure appears to it as fundamentally incompatible with itself, as *irrational*. The clearest type of concept of this order is that which results from Carnot's principle. This affirms, in effect, that the antecedent and the consequent can not be identical for the cosmic process proceeds constantly and irresistibly always in the same direction and without any possibility of reversal. Carnot's principle thus stipulates a "becoming," which is contrary to the principles of conservation. It is noteworthy that while the latter have been accepted both by science and commonsense, on grounds far from conclusive, the former has encountered a lively resistance. Clausius, nearly a whole generation after Carnot, had to discover the principle a second time, and even then, it only gradually secured its legitimate place in physics. Now, this principle is based upon an observation which is perhaps the commonest mankind is capable of making; namely, that heat passes steadily from a warmer body to one less warm, and never conversely. But this observation, however certain and commonplace, is contrary to that causal tendency of mind which imposes the *schema of identification*, and leads the mind to set aside, to declare negligible, whatever opposes it. So it comes about that what persists in phenomena appears to us as essential, as their "substance," and that which changes, as accidental. Now, on the contrary, it is sufficient to consider reality without preconception to become convinced that what remains unchanged is indeed little compared with what undergoes modification. Thus, inertia is, without any doubt, a purely ideal concept; no one has ever seen a uniform movement in a straight line, so, *a fortiori*, no one could see that it would continue indefinitely. And besides, is velocity really more essential than position, and direction than velocity, along a curved line? When I see a red powder (such as oxide of mercury) give rise to a liquid metal and a colourless gas, can I affirm, because I see that the weight remains the same, that the change was without significance? The situation is still worse when we come to the conservation of energy. For, following Carnot's principle, which tells us that energy is incessantly being degraded, we see that its conservation does not at all guarantee the indestructibility of movement. In the state of final equilibrium towards which the universe is steadily tending (the famous *Waermetod* of Clausius), there will no longer be a fall anywhere; and consequently no movement of more than microscopic scale will be possible in it, while energy will none the less be completely preserved.

An "irrational" of a different order from that which Carnot's principle has brought to light, becomes apparent if we consider *sensation*. This, without doubt, is the ultimate source of all our knowledge of the real, but it is easy to see that our modern science excludes that which is its characteristic element. This science does by a somewhat indirect route, banishing it first of all into one of its most complex and least advanced branches, namely, physiology. Once there, it is enveloped in mystery, shut up in the nerve and in the *specific energy* of the nerve. Leucippus and Democritus had already allowed this exclusion, and Descartes (and all modern science with him) maintained it. Aristotle certainly attempted to create a different system of physics, a *qualitative* physics, and the middle ages docilely followed his lead. But we know that this attempt has been absolutely ineffectual. However magnificent it may have appeared at the time, at the present day the edifice is an irremediable ruin: absolutely nothing can be saved from it. And even those who have occasionally tried to incorporate a few fragments of it into modern physics have had to recognize the vanity of their efforts. (The loyal attempts of Duhem were the most brilliant and persevering of this kind ever made.) Vain too have proved to be the objections of philosophers against what they considered unjustifiable prejudice on the part of physicists, as well as the efforts during the first part of the 19th century (especially in Germany) which were directed to elaborating—alongside the physics of physicists, nay, in opposition to it—a different science incorporating and explaining the *quid proprium* of sensation. And, what is more remarkable, is that even in Ger-

many, scientists did not take the trouble to refute these attempts, but simply disdained them, passing them by unnoticed, despite the great authority which their authors—we need only mention the names of Hegel and Goethe—enjoyed at the time.

Another "irrational" arises if we consider the explanation of the *persistent,* of which we have just spoken. This explanation amounts in the last resort to dissolving the whole of reality into the undifferentiated whole of space. It is clear therefore that whatever opposes such a dissolution must play the rôle of an obstacle. In this way, all diversity inevitably appears as an irrational. Perhaps it will not be pointless to make the significance of this assertion more precise by the aid of an example. We know that chemistry has for a long time been constituted as a science distinct from the other physical sciences, and that what differentiates it is its affirmation of the qualitative diversity of substances. Under the name of Mendeléeff's theory, this diversity has been questioned, for it seemed to be demonstrated that the various elementary substances themselves should not be considered completely isolated from each other, but, on the contrary, as derivative from a more general system. As a consequence, on the one hand, of the discovery of radio-active bodies and other discoveries connected therewith, and, on the other, of a series of researches which better enable us to understand the nature of the chemical atom, this current has acquired great strength, and, it may be said to dominate chemical theory at the moment. Clearly, were these efforts to prove completely successful,—in other words, were it possible to reach an explanation of the *entire* behaviour of chemical substances through the spatial configuration of elementary particles (electrons and protons, according to the dominant conception), the specific nature of chemistry would vanish. But, on the other hand, to encounter phenomena fundamentally inexplicable by such configuration, would be to discover the presence of an "irrational." We can realize, then, that such a situation is particularly liable to arise wherever we admit the existence of *separate* sciences. Thus, it is most probable that when our knowledge of biological phenomena is more advanced, and when we are in a position actually to reduce a great number of them to physical chemistry, there will remain, nevertheless, something which we shall not be able fully to account for, and then science will be compelled to admit one or more "irrationals" as being related to the manifestations of organic matter.

However, it should be realized that not all irrationals could be foreseen in this way, by even the boldest speculation. Indeed, from those very phenomena which we believe to be the most fully understood, something inexplicable may arise. This is just what happened during the first decades of this century. We refer to the observations concerning radiation which led to Planck's theory of *quanta,*—a theory so strange and disturbing, because it is so difficult to reconcile it with the remaining hypotheses of physics. And who can say that this surprise will be the last, and that science will not encounter in the future other anomalies just as disagreeable?

The Real and the Necessary.—If now we take a comprehensive survey of this great effort of science to explain and to identify, we see that it aims at a rationalization of the real, that is to say, at its reduction to purely rational elements. The real appears to us as a fact,—a datum. Now reason would like to conceive it as *necessary.* Hence the extravagant attempt to reduce it to space, namely, to nothingness,—or (what amounts to the same thing), to reconstitute it with the aid of space alone. Newton, who had before him the attempts of Descartes, admirably discerned that such an effort could only end in failure. *"A coeca necessitate metaphysica,"* he says at the end of the third edition of his *Principia, "quae utique eadem est semper et ubique, nulla oritur rerum variatio."* One sees, none the less, that the effort has been renewed in our own day by the physics of relativity. But by the very fact that space is there supposed capable of modifying its curvature, of disclosing "wrinkles," it ceases to be always and everywhere homogeneous, and this construction thus escapes Newton's objection to some extent.

This notion of the irrational, as an obstacle which mind constantly encounters in its advance towards an explanation of nature, shows that we should be wrong in charging science with the tendency to dissolve the real into nothingness. For this tendency is quite obviously something which precedes science, something by the aid of which science itself has been created. We begin the penetration of the real with the profound conviction that it should prove itself everywhere penetrable. It might be objected, it is true, that a science confined to the discovery of laws, according to the formula of Comte, seems practically to rule out any intelligibility strictly so-called, by contenting itself with the supposition that nature obeys laws. But apart from the fact that there never has been such a type of science, and in all probability never will be, it is easy to see that even if, in an exposition of science *already made,* it could in strictness, be made to appear as simply a tissue of laws, this would become absolutely impossible so soon as it became a question of science *in the making,* of science in process of development. Francis Bacon believed it possible to establish laws by means of experiments undertaken at random, and summed up later by a sort of mechanical book-keeping. But Liebig has declared that between this variety of science and real science the same relation holds as between the noise made by a child beating a drum and music, and in this the unanimous opinion of scientists would agree with him. In reality, when trying to discover a law the scientist is compelled to select among the conditions of phenomena which are infinite in number, in order to observe those which seem to be more closely connected with each other. What he is intent upon determining is what Lord Balfour calls the *fibre,* that is to say, one of the fibres of which the real is constituted. And simply this fact, that the whole body of the real is not chaotic, but actually consists of a tissue of such fibres, allows us not only to penetrate into it but even to live in it. Now it is only by means of hypotheses concerning the nature and essence of the real that we can seek out this fibre and make a supposition as to its existence and precise place in the scheme of things. Thus, a science directed to the discovery of laws is itself ultimately based upon the conception that nature is intelligible.

The schema of identity constitutes the eternal framework of the mind, and science as a product of the mind, cannot be other than pervaded by it. But, far from submitting to it passively, it reacts, because the real itself reacts, in showing that it is *not completely* penetrable. The idea of the irrational is the manifestation of reality's resistance to intellect. Hence in science, the two tendencies which might be thought opposed to each other,—the idealist tendency toward a negation of the real by rationalization of the diverse, and the realist tendency toward an affirmation of the fundamental irreducibility of the diverse,—co-exist peacefully. It should be noticed that if idealist negation is at the end of its course, physics does not cease for a moment to be fundamentally realistic. The "vortices" of Kelvin, like the "wrinkles" of the relativity theory, show themselves the very moment we try to bring them nearer to ether or space, just as real, just as independent of our own selves, as any common-sense objects. Even more independent, indeed, for, as Planck has shown, science tends in its progress to draw further and further away from the *anthropomorphism* that common-sense imposes on us.

EXPLOSIVES are substances capable of developing a sudden pressure on their surroundings, this development of pressure being caused by the rapid conversion of the explosive substance into gases having a much greater volume than the original explosive, and to the further expansion of these gases by the simultaneous generation of heat. Explosives may consist of gases, liquids, or solids; for example, the explosive mixtures of gas or petrol vapour with air in the internal-combustion engine, and nitroglycerin, and gunpowder are familiar cases of these three classes respectively.

The starting-point in the story of explosives is the discovery by Friar Roger Bacon of the process of purifying a salt by crystallization from aqueous solution. By applying this process to the purification of naturally occurring saline deposits, Bacon obtained, for the first time, pure nitre or potassium nitrate, and one may

imagine that with this pure nitre he attempted to imitate one of the "fiery" or "incendiary" compositions which had long been known and used. Instead of a smouldering and fuming action, the result was the first artificial explosion. As Col. Hime states (*Gunpowder and Ammunition,* 1924), there is no evidence of the knowledge or existence of a real explosive before Bacon's experiments. Fuming, fiery or flaming compositions, such as sulphur and various kinds of natural pitches or bitumens, were not difficult to obtain, and these along with charcoal were easily made into incendiaries. The addition of the natural nitre, natron, etc., can easily be accounted for by a happy accident. Col. Hime, after a thorough examination of all the available evidence, concludes that Roger Bacon was the first maker of the "fundamental" mixture leading to gunpowder. For a surprisingly long time gunpowder (of sorts) was practically the only known explosive.

In the last three-quarters of a century many explosives have been invented or discovered. These modern explosives vary widely in composition, chemical constitution and the kind of explosion they produce. It was not until the 19th century was well advanced that gunpowder had a serious rival either for military or civil employment. Slight modifications in its composition were made, more by accident than by calculation, in order to render it more effective and local in action as a blasting agent for mining. This result was attained mainly by increasing the proportion of sulphur at the expense of the charcoal. Still later, military modifications, known as "brown" powders, were introduced for special uses, in which most of the charcoal was substituted by a "caked cellulose," whilst the proportion of sulphur was reduced to one-fifth and the nitre increased. Speaking generally, the era of new explosive substances started soon after the discovery of the compounds collectively termed gun-cotton or nitrocellulose and nitroglycerine, although fulminating silver and a few similar substances may have been known at a prior date. Gun-cotton and nitroglycerine may be considered as commencing the series of explosives derived from nitric acid in a more or less direct manner. Later, other substances, such as picric acid (or lyddite), were discovered, more or less accidentally, to be explosive under certain special conditions, and following on this discovery it was found that analogous substances (nitro-compounds) of a slightly simpler type of constitution than picric acid could also be induced to explode, especially when submitted to violent or sharp percussion, a mode of explosion distinguished as *detonation.* With more complex nitrogen compounds such as the hydrazines, and, later still, the azides, there have been valuable additions to the list of compounds showing in various degrees the detonating form of explosion.

Careful study of the heat production or absorption in chemical actions of combination or decomposition places practically all chemical compounds in one of two classes: (1) *exothermic* compounds, which give out heat energy during the process of formation, and (2) *endothermic* compounds, which can be formed only by having energy, as heat or in some other form, expended on them during the process of formation. Chalk, water and sand are good examples of exothermic compounds, since much energy—mostly as heat—was dissipated during the formation of these substances, and therefore they are not very active in taking part in chemical actions. Consequently they cannot, with advantage, be employed in explosive compounds or mixtures. On the other hand many explosive compounds are endothermic and, on explosion, liberate a part of their stored-up energy. The essential properties of any explosive are that it should be capable of (*a*) complete or nearly complete conversion into gaseous products, (*b*) generation of heat; (*c*) rapid and simultaneous production of gas and heat. The formation of gases in the products of explosion is usually due to a process akin to combustion or burning, in which the combustible parts of the explosive are oxidized or burned to gaseous oxides such as carbon monoxide, carbon dioxide and steam. This process is called "internal burning" and differs from ordinary burning in that the oxygen required is not derived from external sources, but is already contained in the explosive in some readily available form. The production of heat is due either to the exothermic nature of the products of internal burning, or, in some cases, to the breakdown of an unstable endothermic compound into its elements.

The speed at which explosive action takes place may vary considerably with different substances, and with the conditions under which explosion is initiated, the variation extending from a few metres per second to several thousand metres per second. Explosions at lower speeds may be utilized as sources of power in the internal-combustion engine, where the pressure of explosion is developed sufficiently slowly to move a piston against an external load. Similarly, in small arms or ordnance, the pressure of explosion of the "propellent" charge or cartridge is utilized to drive the bullet or heave the shell along the bore of the weapon. Explosions having speeds of several thousand metres per second have a disruptive or shattering effect (Fr. *brisance*) on their surroundings, the duration of the pressure being so short that it cannot be used to produce a propulsive or heaving effect. Explosive effects of this order are called detonations and are made use of in high explosives for military purposes, also for many blasting explosives used in mines and quarries.

Classification of Explosives.—The Explosives Act of 1875 in Great Britain contains regulations drawn up by the Home Office for the control of the processes of manufacture of explosives and of the conditions of storage and handling of the manufactured products. This act classifies explosives in seven classes, according to liability to ignition by fire, friction, chemical decomposition, etc. Regulations based on similar considerations with particular reference to the needs of military and naval explosives are contained in the service "Magazine Regulations." Explosives may also be classified according to their uses, as: (*a*) *Propellents.* Explosives with low speed of explosion, used in the manufacture of cartridges for small arms (pistols, shot guns, rifles) and ordnance (guns, howitzers, mortars), *e.g.*, gunpowder, ballistite, cordite. (*b*) *High explosives.* Explosives with high speed of explosion, used for filling shell, bombs, mines and for demolitions; *e.g.*, amatol, gun-cotton, etc. Blasting explosives of the dynamite and blasting gelatine types, *e.g.*, gelignite. (*c*) *Initiators.* Explosives of a sensitive nature used in caps, primers, and detonators to initiate the explosion or detonation of less sensitive materials, *e.g.*, mercury fulminate, lead azide, in caps and detonators. (*d*) *Pyrotechnic mixtures.* These materials, although not strictly speaking explosives, require care in handling and storage; they are used for the production of: (1) Smokes, both white and coloured, for purposes of concealment and signalling. (2) Coloured flares and stars, for warlike purposes and for fireworks. (3) Incendiary compositions.

Classification may also be based on chemical considerations, *i.e.*, according as the explosives are simple chemical compounds or mixtures. Within the first class are carbon compounds containing combined oxygen which, on explosion, oxidizes the combustible elements, carbon and hydrogen, to form the gases of explosion. These explosive compounds are formed by the action of nitric acid on various organic materials, and are usually nitric esters or nitro-compounds. The combined nitrogen present in these forms is on explosion mainly liberated as elemental gaseous nitrogen. Included in the second class of explosives are those which, being sensitive, endothermic substances, readily break up into their elements with generation of heat, and do not depend on combined oxygen for their explosive effect. Mercury fulminate and lead azide are examples of this class. Explosive mixtures may contain substances in the above-mentioned group together with non-explosive substances containing oxygen, or consisting of combustible matter. Such mixtures are of two kinds—those containing explosive compounds, *e.g.*, cordite, amatol, and those made up of non-explosive materials, *e.g.*, gunpowder.

Blasting explosives are used in engineering and mining operations for breaking up rock or minerals. For many years gunpowder was the only explosive available, until Nobel introduced dynamite in 1867, followed by blasting gelatine and gelignite in 1887. These blasting explosives may be classified in two groups: (1) High explosives. (*a*) Containing nitroglycerine, *e.g.*, dynamite, gelignite, etc. (*b*) Not containing nitroglycerine, *e.g.*, ammonal, etc. These are fired by a detonator containing mercury fulminate (*q.v.*) or other suitable initiator. (2) Gunpowders. These are of the black powder type, *e.g.*, bobbinite, a typical black powder explosive con-

sisting of potassium nitrate 63·5%, charcoal 19·5%, starch 3%, sulphur 2%, paraffin wax 8% and moisture 3%. Typical compositions of blasting explosives are given in the following tables:

	Blasting gelatine	Gelatine dynamite	Gelignite	Dynamite
Nitroglycerine	90·6	74·1	61·1	75
Nitrocellulose	8·8	5·9	3·8	..
Potassium nitrate	..	15·7	27·6	..
Woodmeal	..	4·0	7·2	..
Chalk	0·6	0·6	0·3	..
Kieselguhr	..	..	..	25

Permitted Explosives

	Super-rippite	Rex powder	Denaby powder	Roburite	Dynobel
Nitroglycerine	52	12	..	..	32·5
Nitrocellulose	3	..	..	..	0·75
Potassium nitrate	14·5	..	13·5	..	..
Ammonium nitrate	..	59·5	34	60·5	..
Potassium perchlorate	..	..	..	..	27
Trinitrotoluene	..	..	13	16·5	..
Charcoal	..	..	..	..	..
Woodmeal	..	7·7	..	..	9·5
Starch	..	..	..	..	..
Sulphur	..	..	..	..	..
Paraffin wax	..	..	..	..	..
Ammonium chloride	..	..	19·5	22·5	..
Sodium chloride	..	19·5	..	..	..
Potassium chloride	8	..	..	..	..
Ammonium oxalate	..	..	..	..	29·5
Borax	16·5	..	..	..	..
Moisture	6	1·2	0·75	0·75	0·75

Of these foregoing groups certain explosives may safely be used for getting coal in fiery mines, and are accordingly on the British list of permitted explosives. All are explosives of the mixture class, containing explosive and non-explosive compounds. Among the latter are inert substances such as chlorides and oxalates which act as coolers in reducing the flame temperature. The individual types of explosive will now be described, but gunpowder and picric acid (lyddite) are dealt with in separate articles under their own headings.

Nitroglycerine and Nitrocellulose.—Nitroglycerine, glyceryl trinitrate or trinitrin was first made by Sobrero in 1846. It is manufactured by spraying glycerol (glycerine) into a mixture of nitric and sulphuric acids; the nitroglycerine separates as an oily liquid and is purified by washing and filtration. Its use as an explosive was suggested by Nobel in 1863, but owing to its sensitive nature, the danger in its transport and use prevented its employment unless mixed with solid materials to form a plastic mass which could be handled with safety. Such mixtures are cordite, dynamites and blasting gelatines. Nitroglycerine, a liquid of density 1·6, exists in two solid forms melting at 2° C and 13° C. When soaked in absorbent paper it burns quietly with a green-edged flame, but when heated it decomposes just before boiling, and finally detonates. It is used medicinally for the treatment of asthma and angina pectoris in the form of a 1% solution in alcohol.

Nitrocellulose is the name given to the nitric esters formed by the action of nitric acid on cellulosic materials, *e.g.*, purified cotton or wood pulp. Pelouze in 1838 discovered that cotton could be converted into a violently inflammable substance by nitration with nitric acid, and in 1845 Schönbein discovered its value as a high explosive, also improving the method of preparation by the addition of sulphuric acid to the nitric acid used in nitration. Many attempts were made to utilize this substance as an explosive for civil and military purposes, but owing to a series of serious accidents in manufacture, storage and use, it was abandoned temporarily. Sir Frederick Abel of the Royal Gunpowder Factory, Waltham Abbey, England, discovered subsequently that these dangers were due to the presence in the nitrocellulose of minute traces of acid-forming substances which were not removed by the processes of washing then in use and caused a cumulative decomposition of the nitrocellulose, finally resulting in explosion. On the basis of these discoveries improved methods of washing the nitrocellulose were introduced and resulted in the manufacture of a safe, stable product.

The chemical action between cellulose and nitric acid may be represented by the equation

$$C_6H_{10}O_5 + x\,HNO_3 = C_6H_{(10-x)}O_{(5-x)}(NO_3)_x + x\,H_2O.$$

The proportion of nitrogen in the form of nitrate groups is represented by the variable quantity, x, the value of x depending on the time and temperature of nitration and on the composition of the mixture of nitrating acids. The function of the sulphuric acid is to remove water formed in the action and thereby to prevent dilution of the nitric acid. The properties of the nitrocelluloses vary with the percentage of nitrogen they contain (*i.e.*, according to the value of x), particularly in their behaviour towards organic solvents. Nitrocellulose containing 13·0% or more nitrogen content can be detonated by percussion or by the use of a detonator. Their chief properties and uses are summarized in the following table:

% Nitrogen	Name	Properties	Chief uses
10·7–11·2	..	Soluble in alcohol	Celluloid plastics
11·2–11·7	..	Soluble in ether +alcohol	Photographic films. Artificial silk
11·8–12·3	Pyroxylin or collodion cotton	Soluble in ether +alcohol. Insoluble in alcohol	Cellulose lacquers. Smokeless powders
12·6–13·5	Gun-cotton	Insoluble in ether+alcohol. Soluble in acetone	Gun-cotton slabs. Smokeless powders.

The manufacture of a smokeless propellent consists in the mechanical incorporation of the nitrocellulose with the other constituents in such a manner as to give a product which is gelatinous or colloid in its nature and free from the porosity characteristic of untreated nitrocellulose. In the case of nitrocellulose propellents, gelatinization is effected by kneading the nitrocellulose with a volatile liquid such as acetone, the product being a dough-like mass which can then be rolled into sheets or pressed through dies to form strips or cords. The volatile solvent is then removed by heating, leaving the nitrocellulose in a horny non-porous condition. With nitroglycerine propellents, gelatinization can be effected in various ways: (1) Heat treatment. In this method the mixture of wet nitrocellulose with nitroglycerine and any other constituents of the powder is passed between hot rollers which first expel moisture and finally cause absorption of the nitroglycerine by the nitrocellulose to form a translucent mass, *e.g.*, ballistite. In some cases non-volatile substances are added to the mixture which facilitate gelatinization and act as stabilizers in lessening subsequent deterioration of the finished propellent, *e.g.*, Ardeer cordite. The gelatinized mass can then be rolled or pressed into the required shape and is ready for use. (2) Kneading with a volatile solvent, as in the case of nitrocellulose powders, followed by pressing and drying, *e.g.*, cordites.

The chief drawbacks of smokeless propellents are the erosion of the bore of the gun caused by their use, and the brilliance of the flash of discharge, the latter being specially undesirable in the case of propellents used for warlike purposes. Erosion is caused by the high temperature of the gases of explosion and is less with powders of the nitrocellulose type than with those containing nitroglycerine. This effect is due to the deficiency of oxygen in nitrocellulose and to the excess of oxygen in nitroglycerine. An illustration of this is found in the cordites: Cordite Mark I. is highly erosive owing to its high percentage of nitroglycerine, but cordite M.D. is much less so. Reduction of the temperature of explosion can be effected by the admixture

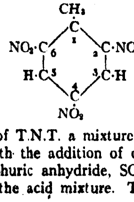
of substances which absorb heat or produce gaseous nitrogen in place of the exothermic oxides of carbon in the gases of explosion. This not only has the effect of reducing erosion but also reduces the brightness of the flash of discharge.

Propellents.—Propellent explosives are required for: (1) The propulsion of shell or other projectiles in rifled arms: (*a*) ordnance, *e.g.*, guns, howitzers, mortars; (*b*) small arms, *e.g.*, pistols, rifles. (2) The propulsion of shot in smooth-bore guns for sporting purposes. For many years the only explosive available as a propellent was gunpowder which is far from being an ideal material for the purpose. Its uncontrolled rate of burning and smoke-producing properties are the chief obstacles to its use. The discovery of nitrocellulose and nitroglycerine led to the development of an entirely new type of propellent, usually called smokeless powder. These propellents differ not only in being smokeless, but also in that the rate of burning is uniform owing to the non-porous texture of the powder preventing the hot gases of explosion penetrating below the surface layer.

Modern smokeless propellents may be either nitrocellulose propellents, consisting mainly of nitrocellulose, or nitroglycerine propellents, consisting mainly of nitrocellulose plus nitroglycerine. In addition to these principal constituents, small quantities of other substances are in some cases added (*a*) to act as "stabilizers" in preventing the deteriorating action of acid substances formed by the slow decomposition of the nitrocellulose or nitroglycerine, or (*b*) to act as "moderants" in regulating the rate of burning of the propellent. Typical compositions of some modern smokeless propellents are given in the following table:

	E.C.	Kynoch	Ballistite	Cordites Mark I.	Cordites M.D.	Cordites R.D.B.
Nitrocellulose	79	52·1	62·3	37	65	52
Nitroglycerine	..	..	37·6	58	30	42
Stabilizer:						
Camphor	4	..	..	..	..	..
Vaseline	..	..	..	5	5	6
Moderant:						
Dinitrotoluene	..	10·5	..	..	..	..
Potassium nitrate	4·5	1·4	..	..	..	..
Barium nitrate	7·5	22·2	..	..	..	..
Woodmeal	3·8	2·7	..	..	..	..

Trinitrotoluene (T.N.T.).—This is a derivative of toluene and in some respects similar to picric acid (*q.v.*). Toluene, $C_6H_5{\cdot}CH_3$, is a liquid boiling at 110° C, obtained from the lower-boiling portions of coal tar (*q.v.*) or from Borneo petroleum. Generally speaking, it is more easily brought into chemical reaction than benzene, C_6H_6, but not so easily as phenol, $C_6H_5{\cdot}OH$. Nitric acid acts on it in several stages, the highest stage being the trinitro-compound or T.N.T., $CH_3{\cdot}C_6H_2(NO_2)_3$. The lower stages of nitration are represented by mono- and di-nitrotoluene. They and T.N.T. itself were employed, either alone or mixed, in the dye industry for quite a long time before any explosive property was associated with them. There are six possible modifications of trinitrotoluene, these isomerides differing in form, colour, melting point, chemical reactivity, etc. (*see* ISOMERISM). The ordinary variety of T.N.T. used as an explosive is represented in the following graphic formula as the most symmetrical isomeride, *i.e.*, as 2:4:6-trinitrotoluene:



In the manufacture of T.N.T. a mixture of nitric and sulphuric acids is employed with the addition of oleum or sulphuric acid containing some sulphuric anhydride, SO_3, thus minimizing the amount of water in the acid mixture. To this mixture the toluene is gradually added with constant agitation, jacketed iron vessels being employed so that cooling or heating may be arranged as required. Nitrous fumes are conducted away and reconverted into nitric acid. The oily product is separated from the dilute mixed acids, which are run off and concentrated for further use. The oil is poured into water, where it solidifies, and is then washed free from adhering acids and purified by treatment with a solution of sodium sulphite, which dissolves all the unsymmetrical trinitrotoluenes (present as by-products) but has no action on the symmetrical variety.

The pure substance melts at 82° C, and when heated to about 150° C it gives off a little gas which is much increased at about 180° C; the melt darkens as the temperature rises, and intumescence may take place at or below 300°. By rapidly heating a few grams of the melted substance in a test tube over a large flame, it is possible to get quite a marked explosive effect. When large quantities catch fire, the burning may become explosive, although this substance, when pure and alone, is one of the safest of high explosives. Some unexplained explosions have taken place, which may possibly have been due to the presence of a trinitrobenzoic acid, produced by too drastic nitration, such an acid being more sensitive than T.N.T. itself. Minute quantities of substances containing available oxygen, *e.g.*, chlorates, nitrates, etc., in contact with nitro-compounds, such as trinitrotoluene, greatly increase the sensitiveness of these compounds to heat or percussion. Nitrate of ammonia, however, is almost the only substance of this class capable of being safely employed in admixture with trinitrotoluene or like substances on a large scale (*see* below).

Trinitrobenzene, $C_6H_3(NO_2)_3$, is difficult to make, otherwise it would doubtless be largely employed for both civil and military purposes. The lower nitration stages—mono- and di-nitrobenzenes—are constituents of various blasting compositions.

Amatol.—Ammonium nitrate has been in use for a considerable time for blasting purposes in mine work, especially coal mining, and was first employed with trinitrotoluene in 1914. After the safety of this mixture had been proved through a wide range of proportions and conditions, it was largely employed under the name of amatol, a composition of 80 parts of ammonium salt to 20 of trinitrotoluene being favoured. The advantage of such a mixture is that practically no carbon is left unburnt on its explosion. The ammonium nitrate is a self-combustible and may, in favourable circumstances, respond to a detonator. The necessity for using special explosives in coal mines instead of ordinary gunpowder drew attention to ammonium nitrate as not being so hot, producing much steam and nitrogen and no red-hot solid particles, and therefore less liable to ignite coal dust or inflammable gases. Ammonium nitrate is hardly to be regarded as a possible substitute for the nitre of gunpowder owing to its deliquescent properties. Compositions of nitro-naphthalene, paraffin, rosin, etc., were formerly used for blasting, being mixed as dry powders, pressed into form, and waterproofed by treatment with paraffin wax. Since then many changes have been made on this type of explosive, particularly in regard to the aromatic nitro-compounds introduced, generally with a view to greater safety or power.

Ammonal.—The enormous amount of heat evolved by the oxidation of some powdered metals, such as that of aluminium in thermite compositions, led to its being introduced into ammonium nitrate mixtures. For ordinary blasting work (out-of-doors) one uses a composition such as: ammonium nitrate, 72%; aluminium, 25%; charcoal, 3%; or ammonium nitrate, 47%; aluminium 22%; T.N.T., 30%; charcoal 1%. The velocity of explosion of these mixtures may be in the vicinity of 4,000 to 4,500 metres per second. For coal mines the aluminium must be reduced to a few units per cent, the larger proportion of ammonium nitrate keeping down the temperature; thus: ammonium nitrate, 93–95%; aluminium, 2·5–3·5%; charcoal, 2–3%.

LIQUEFIED GASES

Liquid Oxygen Explosives consist of mixtures of liquid oxygen with combustible substances. The combustible substances (lamp-black, wood pulp, cork dust, hydrocarbons absorbed in inert materials, or even pulverized metals) are packed in absorbent paper or cloth cartridges, and immediately before use the cartridges are soaked in liquid oxygen until saturated. The cartridges are removed from the liquid and fired with a detonator in a manner similar to that employed with ordinary dynamites. In the process of explosion an extremely rapid reaction takes place between the liquid oxygen and the combustible material, with the production of a large quantity of gas at high temperature and pressure. The mechanism of the explosion is similar to that taking place in other explosive mixtures, except that the oxygen supply is obtained from liquid oxygen instead of from chemically combined oxygen. The advantages of these explosives are that neither the cartridge nor the liquid oxygen are explosive until brought together and, due to the low temperature (−183° C) of liquid oxygen, the oxygen completely evaporates in a relatively short time after the cartridges have been removed from the liquid, and they are then once more non-explosive. This latter fact gives rise to the disadvantage, however, that the explosive strength diminishes as the oxygen evaporates, and if too long a time elapses before the cartridge is fired, insufficient oxygen is available for complete combustion to CO_2 (carbon dioxide), and large quantities of toxic CO (carbon monoxide) may be formed. This constitutes a hazard in the use of this explosive in underground mining. Under favourable conditions liquid oxygen explosives are considerably cheaper than dynamite.

Practical Applications.—In practice, liquid oxygen is manufactured at the mine or quarry by liquefaction of air and subsequent separation of the nitrogen by fractional distillation. Liquid oxygen is a bluish liquid and boils at −183° C. It cannot be stored under pressure but is kept in double-walled vacuum-insulated metal containers and allowed to evaporate slowly to compensate for the heat conduction from the surroundings. These containers have been built with capacities as high as 1,000 gal., but the ordinary sizes hold 4 to 25 gallons. The cartridges are soaked in insulated dipping containers just before use, and are then loaded in the bore-holes and fired as soon as possible.

An investigation of liquid oxygen explosives by the U.S. Bureau of Mines has shown that the packing density, or weight of combustible in unit volume of the cartridge, is one of the most important factors in determining its explosive characteristics. Lamp-black or gas-black was shown to be the optimum material for most purposes. The available life of a cartridge, or time after removal from the liquid during which it could be exploded effectively, was found to augment with increasing cartridge diameter; *e.g.*, a cartridge 1½ in. in diameter had a life of about 30 min., whereas one 6 in. in diameter had a life of several hours. The explosive strength of the cartridge was found to bear a direct relation to the amount of oxygen present per unit weight of combustible, and greater explosive effect was obtained by increasing the packing density.

The explosive strength of the cartridge was found to be a variable quantity which depended upon the composition of the cartridge material, density of packing, size of cartridge and time of evaporation after cartridges are removed from the liquid and before firing. Cartridges begin to lose strength almost from the moment they are removed from the liquid. It has been shown by tests with the ballistic pendulum (*see* BALLISTICS) at the explosives experiment station of the U.S. Bureau of Mines that 1½ in. cartridges packed with gas-black, fired 5 min. after removal from the dipping container, may have a strength 10% greater than 40% gelatin dynamite, volume for volume; but no cartridge material has been found which will develop a greater relative strength than this. If fired after 10 min. evaporation, the strength is about 95% that of dynamite. On the other hand, if longer life is desired, a cartridge packed to a lower density will retain enough oxygen for complete combustion for 10 min., but will have an explosive strength less than the more dense cartridge. After 5 min. evaporation the strength of such a cartridge will be about 99% that of 40% gelatin dynamite, and after 10 min. evaporation about 80% the strength of dynamite. The rate of detonation of liquid oxygen explosives ranges from 3,000 to 6,000 metres per second, depending on the composition of the combustible material.

History.—The possibility of using liquid oxygen as one of the components of an explosive was perhaps first suggested by Sprengel, in 1873, who stated that the *beau ideal* of a detonating explosive was a mixture of eight parts of liquid oxygen and one part of liquid hydrogen. The possibilities were foreseen at this early date, but obviously they could not be given serious consideration until liquid oxygen could be produced in commercial quantities. In 1895, Linde evolved a method of producing liquid air commercially, and in 1897 he introduced a liquid air explosive "oxyliquit." This was first tried out in 1895 in a cross-cut of the Penzberg coal mine in upper Bavaria; but the first large-scale blasting was not done until 1899, when liquid oxygen explosives were used in driving the 12 m. Simplon tunnel between Italy and Switzerland. Little further work was done until the beginning of the World War, when the need for conserving glycerine and nitrates forced Germany to look for substitutes for use in industrial explosives. Under this stimulus, the use of liquid oxygen explosives grew until in 1917 there was a total of 160 coal, metal, salt and potash mines using liquid oxygen explosives where the plants had an hourly production of 4,860 litres. The use has dropped off to some extent since 1918, but in 1926 there was still more than 1,000,000 litres of liquid oxygen produced in Germany for blasting purposes. The explosive was used with some success after the war in the iron mines of Lorraine, and is now used to a limited but increasing extent in open-cut blasting in the United States (mainly coal) and in Chile (copper ore).

Liquid Carbon Dioxide is a new agent employed to blast coal in the United States. The liquid is compressed in a steel shell 4 in. in diameter and 3 ft. in length to a pressure of about 1,500 lb. per square inch. At this pressure the shell contains 4 lb. of the liquid. In the centre of this shell is a heating element consisting of a mixture of sodium chlorate, aluminium and charcoal, with means for igniting it electrically. One end of the shell is closed by a metal disc which is sheared when the shell is fired. The heating element provides sufficient heat to gasify the carbon dioxide and increase its pressure to about 20,000 lb. per sq.in., at which pressure the disc is sheared and the gases are released. In blasting, the shell is placed in a bore-hole 4 in. in diameter and tamped with stemming. The shell is so placed that the gases are discharged at the bottom of the bore-hole and thus break down the coal. It may be added that, whereas liquid carbon dioxide may be safely used in underground coal mines, liquid oxygen can not, because its long and hot flame may ignite a possible accumulation of fire-damp or a cloud of coal dust and start an explosion. (G. St. J. P.)

UNITED STATES

Any substance that changes chemically and with great rapidity from its natural state to that of a large volume of gases, accompanied with heat, is classed as an explosive in America. The transportation of explosives in the United States is regulated by the Interstate Commerce Commission with the co-operation of the Bureau for the Safe Transportation of Explosives and the Institute of Makers of Explosives. In the United States explosives may be classified as follows: blasting powders, dynamites, other high explosives, initiating explosives (detonators), military explosives, shotgun, rifle and common powders.

Blasting Powders.—Black powder for blasting purposes contains sodium nitrate instead of the more expensive potassium nitrate, together with charcoal and sulphur. This is known as "B" blasting powder. About 80% of the blasting powder manufactured in the United States is used in the mining of coal. The granulations of black blasting powder vary widely. Its strength is comparatively low and is the same for all granulations, but as the finer granulations burn faster than the coarser ones their effect is a

trifle more shattering. Black powder containing potassium nitrate, instead of sodium nitrate, and known as "A" blasting powder, is used for black sporting powders, for the manufacture of safety fuse, for pyrotechnics and, to a very limited extent, in quarrying dimension stone. In recent years a mixture of various grains of black blasting powder has been used successfully, under certain conditions, for column-loading in deep-hole blasting in quarries, in conjunction with Cordeau-Bickford detonating fuse extending the entire length of the bore-hole. Granulated black powder is also compressed into cylindrical pellets having a central perforation, which are wrapped in cartridge paper and fired by a fuse.

Dynamites.—The majority of dynamites in the United States consist of an explosive compound, usually nitroglycerine, mixed with an absorbent composed of sodium nitrate and wood meal or other carbonaceous material. The proportions are so chosen that the mixture will have an excess of available oxygen on explosion and therefore will produce a minimum of carbon monoxide and other poisonous gases. The use of Kieselguhr as an absorbent was abandoned many years ago in the United States. A dynamite containing no nitroglycerine, but nitrostarch and a mixture of oxidizing and carbonaceous ingredients, finds considerable use in the United States.

It has the advantage of not freezing at any temperature and of not producing headaches, which are often caused by nitroglycerine dynamites. Dynamites are divided into the following types: straight nitroglycerine, ammonia, gelatine, ammonia gelatine, blasting gelatine and permissible dynamites. All dynamite, with the exception of the larger diameters, is packed in cartridge form by large, semi-automatic machines. Straight nitroglycerine dynamites are made in strengths from 15% to 60%. Their percentage strength represents the equivalent of the same proportion of liquid nitroglycerine. The nitroglycerine is mixed with a combustible absorbent which contributes to the force of the explosion.

Straight nitroglycerine dynamites have a relatively high rate of detonation, and therefore are used wherever a quick action or a shattering effect is required. They resist water fairly well. Practically all dynamites made in the United States, shown in the above classification, with the exception of blasting gelatine, contain low-freezing ingredients which prevent freezing at prevailing winter temperatures. These low-freezing ingredients are either tetranitrodiglycerine, nitro-compounds, or both.

Ammonia dynamites, the most widely used, contain in place of part of the nitroglycerine ammonium nitrate. This salt slows down the velocity of detonation somewhat, and makes the action less shattering. They are safer to handle than straight nitroglycerine dynamites, and their gases are less objectionable.

Gelatine dynamites contain, instead of nitroglycerine, a colloidal solution of nitrocotton in nitroglycerine, absorbed in a mixture of sodium nitrate and wood meal. Their plastic consistency allows them to be extruded through a nipple of the required diameter into paraffin-paper shells to form cartridges. Gelatine dynamite is water-proof, and is used for wet work and under-water blasting. The strength of these dynamites ranges from 20% to 90%. They produce the least amount of noxious gases of any type of explosive.

Ammonia gelatine dynamites resemble the above except that a portion of the nitrocotton-nitroglycerine colloid is replaced by ammonium nitrate. Their explosive characteristics resemble gelatine dynamite.

Blasting gelatine consists of nitroglycerine in which has been dissolved nitrocotton to form a jelly, together with a small proportion of an antacid, such as chalk. It is a tough, rubbery material upon which water has no effect, and is only used where the greatest possible concentration of energy is required. Because nitroglycerine has a better colloiding action on nitrocotton than the low-freezing tetranitrodiglycerine, the latter is not used in blasting gelatine. Blasting gelatine is the strongest and one of the quickest explosives manufactured for commercial use.

Permissible Explosives.—This is one which has passed certain tests of the U.S. Bureau of Mines to determine its safety for use in coal mines, and is permissible when used in accordance with conditions prescribed by the bureau.

The principal characteristics of permissible dynamites are that the flame of explosion is relatively cool, small and of short duration. There are three types of permissible explosives, viz., nitroglycerine, ammonium nitrate and gelatine. Very little of the nitroglycerine type of permissible explosive is made. The principal type permissible contains about 10% nitroglycerine and a large proportion of ammonium nitrate, together with a small amount of wood meal or other carbonaceous ingredient. The relatively cool flame from the explosion of ammonium nitrate does not ignite gas or dust in a coal mine when used under conditions prescribed by the Bureau of Mines. Gelatine permissible dynamites contain flame-quenching salts.

A recent advancement in the explosives industry is the production of bulky dynamites. One hundred pounds of straight nitroglycerine dynamite contains approximately 200 cartridges of the 1¼ in. by 8 in. size. Between 60% and 70% of all dynamite used in the United States is of this standard size. Because of the desirability in many operations of spreading the explosive force along the bore-hole instead of concentrating it at the back, ammonium nitrate dynamites have been increased in bulk until certain of them are now manufactured to contain 500 of the above size cartridges to the hundred pounds. The advantages attained are a less shattering action and a resulting economy. In recent years considerable improvement has been made in the reduction of the amount of poisonous gases evolved on explosion of dynamites. This has been accomplished mainly by improving the oxygen balance of the ingredients and reducing the weight of the paper wrapper.

Other High Explosives.—Practically all nitroglycerine made in the United States consists of a mixture of nitroglycerine and tetranitrodiglycerine, or a mixture of nitroglycerine and nitrated sugar. These are made by nitrating a mixture of glycerine and diglycerine, or a solution of sugar in glycerine. Liquid nitroglycerine transportation over common carriers in the United States is forbidden. Other than its use in the manufacture of explosives, its only application is in oil-well shooting. Very small quantities of nitroglycerine are used for medicinal purposes in glonoin, a dilute solution of nitroglycerine in ethyl alcohol.

Cordeau-Bickford (detonating fuse) consists of a small-bore lead tube made in lengths of several hundred feet and containing compressed trinitrotoluene (T.N.T.). When a blasting cap is detonated at one end of Cordeau-Bickford, it initiates a detonation of the trinitrotoluene, which detonation travels along the explosive at a high uniform velocity. This detonating fuse finds a wide use in simultaneously firing a series of loaded bore-holes, for which purpose it is put into the bore-hole with the dynamite and extended to a main line above ground. When the main line of fuse is detonated, the explosive wave travelling along detonates each branch leading to the several bore-holes, and thus detonates all of the charges in rapid, almost simultaneous succession. (Liquid oxygen [L.O.X.] and liquid carbon dioxide as explosives are described below.)

Initiating Explosives.—Initiating explosives comprise many organic compounds and inorganic salts, only a few of which have obtained commercial importance as constituents of detonator compositions. The most important and the most widely used at present is mercury fulminate (*q.v.*). This is very sensitive to heat, shock and friction and detonates with great violence. When used in detonators it is usually mixed in the proportion of 80 parts of fulminate to 20 parts of fine, dry potassium chlorate. The ordinary No. 6 detonator contains one gram of this mixture. Lead azide (lead trinitride), although not used in the United States, is another important initiating explosive.

It is used in blasting caps, but only as a priming or top charge over organic explosives which do not by themselves ignite by the flame from a fuse. It is frequently mixed with lead trinitroresorcinate to improve the ease of ignition by a fuse. Organic explosives not detonated directly by the spark from a fuse, such as tetryl (tetranitromethylaniline), T.N.T. (trinitrotoluene), picric acid (trinitrophenol) and nitromannite are frequently used in detonators as base charges beneath an initiating charge of fulminate of mercury.

Military Explosives.—Military explosives comprise those used for such purposes as filling shell, submarine mines, grenades, bombs, torpedoes, and for boosting charges. The most important explosives of this class are T.N.T. and amatol, a mixture of T.N.T. and ammonium nitrate. In amatol the proportion of ammonium nitrate varies from 80% for large shell to 50% for small shell. It is comparatively difficult to detonate, and therefore relatively safe to handle. An amatol bursting charge in a shell requires a booster charge, because small amounts of fulminate of mercury are not sufficient to detonate it. Booster charges consist of tetryl, detonated by a small amount of fulminate of mercury. Amatol is used for shell larger than those using T.N.T.

Picric acid, or trinitrophenol (*q.v.*), for use as a shell filler, has been largely displaced by T.N.T. and amatol, principally on account of inconvenience in the manufacture of picric acid and the fact that it is likely to form, with the metal of the shell, highly sensitive salts which might cause premature detonation. Like amatol, picric acid requires a booster charge for proper detonation. Ammonium picrate was used during the World War as a shell filler for very large shell. Gun cotton (*q.v.*) was once used in torpedoes and submarine mines, but has been rendered obsolete, in the United States, by T.N.T. and amatol. Nitrostarch explosives were used extensively during the World War for filling hand and rifle grenades.

Shotgun, Rifle and Cannon Powders.—These powders consist of two types, viz., black sporting powder and smokeless powder. Black sporting powder is a potassium nitrate powder, and, although formerly used extensively as a load for shotgun shells and rifle cartridges, it has been replaced largely by smokeless nitrocellulose and nitrocellulose-nitroglycerine powders. Nitrocellulose (single base) powders do not give as much heat in combustion as nitrocellulose-nitroglycerine (double base) powders, and are therefore not as severe on the rifling of the barrel.

Single base powders are made by colloiding nitrocotton of a suitable degree of nitration with a solvent, forming into grains of various sizes and shapes and dried. Double base powders are made by colloiding nitrocotton with nitroglycerine and a solvent and forming into grains. As a rule smokeless powders for large guns are made in the form of cylindrical pellets containing several longitudinal perforations. The object of these perforations is the attainment of lower breech pressure and higher average pressure during the travel of the projectile along the barrel. This is effected by a uniformly accelerated burning speed, due to the increasing area of the internal perforations as combustion proceeds.

(N. D. R.)

EXPONENT, a modern term used in algebra to indicate the number of times the expression to which it refers is to be taken as a factor. For example, in the monomial $3x^2$, the exponent of x is 2 and it states how many times x is taken as a factor; that is, $3x^2$ means $3xx$. Although the idea of power of a number is very old, and the use of the exponent (but in a form unlike the present one) is found as early as the 14th century, the actual form a^3 first appears in Descartes's *La Géométrie* (1637). The early concept of exponent was broadened as algebra developed, and gradually meanings were found for such forms as a^{-n}, a^0, $a^{\frac{1}{2}}$, $a^{\sqrt{2}}$, and so on, the exponent being any kind of number whatsoever. As new types of exponent were suggested, the question arose as to what meanings were to be assigned to them so that the fundamental laws of positive integral exponents should be retained. This desideratum led to defining a^0 in such a way that the law $a^m a^n = a^{m+n}$ should remain valid; that is, $a^0 a^n$ must continue to be a^{0+n}, or a^n. Evidently this required that a^0 should be equal to 1, excepting when $a=0$. Similarly, $a^{\frac{1}{2}}$ came to mean $\sqrt{a}$, $a^{\frac{3}{2}}$ to mean $\sqrt{a^3}$, and a^{-n} to mean $1/a^n$. These facts had long been known, but without our modern exponential symbols. In like manner meanings came to be assigned to $a^{\sqrt{2}}$ and even to $a^{\sqrt{-1}}$. Indeed, one of the most interesting relations, and most fruitful, is that which asserts that $e^{\pi i} = -1$, where e is the base of the natural system of logarithms, π is the incommensurable ratio of the circumference of a circle to the diameter, $i = \sqrt{-1}$, and -1 is the negative unit. It is by means of this relation, to which the name of Euler is attached, but which is easily derived from the relation $\phi i = \log(\cos\phi + i\sin\phi)$, due to Cotes (1722), that it can be shown that every number has an infinite number of logarithms, only one being real. Even before the time of Cotes it appears that De Moivre (1707) knew a similar relation. The first algebraist to explain fully the significance of negative and fractional exponents was John Wallis (1655), his work being supplemented soon after (1669) by Newton. (D. E. S.)

EXPORT CREDITS, a post-war scheme adopted by the British Government to assist British export trade. The export credits scheme was initiated by Mr. Lloyd George's coalition government in the autumn of 1919 as a means of facilitating the finance of export business and of promoting the restoration of British trade. Importers in many markets found it difficult at the time to pay cash or do business on short-term bills; and it was felt that trade could be secured if facilities were provided for financing transactions which, owing to the length of credit required, or for other reasons, would not be acceptable to the banks.

Power was also taken to insure goods against risks of an abnormal or exceptional nature, but this part of the scheme has remained inoperative. At first the application of the scheme was limited to business with certain European States, viz., Finland, the Baltic States, Czechoslovakia, Yugoslavia, Rumania and others. This restriction was due in part to a concomitant policy of assisting in the economic reconstruction of countries which had been specially disorganized by the World War. In 1921 the sphere of operations was enlarged to include the whole world, subject to exceptions adopted in the administration of the scheme.

The legislation governing the scheme is contained in the Overseas Trade (Credit and Insurance) Act 1920; in an amending Act of 1921; and in the Trade Facilities Act 1921–26. It is administered on behalf of the Board of Trade by the export credits guarantee department of the department of overseas trade, with the assistance of an advisory committee of business men. The aggregate amount outstanding in respect of credits at any given time may not exceed £26,000,000. Credits and guarantee may only be given for British goods. The period within which new credits may be given expires in Sept. 1929.

System of Guaranteed Drafts.—Under the original scheme the export credits department made advances to the exporter in cash up to 80% of the cost of the goods, but early in 1921 an important modification was introduced, the object of which was to bring the method of operation into closer correspondence with the normal machinery of trade. Instead of making advances, the department was authorized to guarantee drafts drawn against the shipment of export goods. The advances system was in consequence discontinued, and the bulk of the business done under the scheme was effected under the guarantee plan. The scheme was further re-modelled in July 1926 as the result of recommendations made by a committee appointed in the preceding year to examine the whole question of credit insurance. The facilities now offered may be classified as follows: (1) Facilities of an insurance character, by which the department's guarantee is given without recourse to the exporter. In these cases the guarantee may not exceed 75% of the amount of credit granted to the importer. (2) Facilities of a financial character, by which the guarantee is given with full recourse to the exporter. In these cases the guarantee may be for the full amount of the credit granted to the importer. (3) Facilities of an intermediate character, by which the guarantee is given for the whole or part of the credit either without recourse to the exporter or with such recourse as may be agreed. In these cases the exporter will not be relieved of more than 75% of the risk on the bill unless approved security is provided.

A floating contract has also been introduced which provides assistance to exporters without each specific transaction having to be submitted to the department. An exporter can now obtain a contract from the department covering each of the countries with which he is doing business on the basis of bills of exchange. Cover to an agreed amount is given for a forward period of six months. Appropriate premia are charged in all cases.

The total business up to Dec. 1927 was about £1,750,000 under the advances scheme; £6,260,000 under the first guarantee scheme (1921–26), and £834,000 under the new guarantee scheme (1926). Losses were made under the advances scheme but the credit insurance committee found that under the guarantee scheme no material profit or loss had been made up to 1926.

As the limit fixed by the original act was £26,000,000 it is clear that the scheme has not been taken advantage of to the extent expected. This may be due to various causes. It has taken time for the scheme to become widely known; business men have been perhaps sceptical about the handling of such matters by a government department; there may have been complications and rigidities of practice such as would discourage applicants. Published figures, however, show that very much larger amounts of credits have been sanctioned than have actually been taken up—presumably because the applicant eventually failed to secure the business for which the credit was required, or perhaps was ultimately able to finance it without assistance from the department. They also show that the scheme in its latest form is making much more rapid progress. On the whole, the figures indicate that the scheme has been helpful to British trade at a difficult juncture.

EXPORT DUTIES. Customs duties on the exportation of commodities are rarely levied, it being usually held by Governments that exportation is to be encouraged in the interests not only of the exporter but of the general community. Indeed, in the history of taxation instances of the payment of bounties upon exports to encourage trade are commoner than export duties. Generally, taxes upon the exportation of commodities are incident upon the producers of the taxed commodities. In ordinary cases, the foreign importer cannot and will not pay the extra cost of production caused by the tax, which has, therefore, to be paid by the exporter. If, however, a country possesses a monopoly product essential to the foreign importer, then, within certain limits, an export tax upon that commodity will be paid by the foreign importer because he is willing to buy it at a price enhanced by the tax.

Cases have occurred in which the manufacturers of a nation have appealed to their Government to tax the exportation of a valuable raw material with the purpose of monopolizing for themselves the use of that material or to prevent its use abroad. Thus it is on record that when the first crucible cast steel was made in England by Huntsman, the Sheffield manufacturers unsuccessfully appealed to the Government to tax the exportation of that steel to France to prevent the French cutlery manufacturers from using it.

EXPORT OF CAPITAL: *see* Capital, Export of.

EXPORTS, a term used to describe goods sent out of a country by its traders. To the individual trader who sells it abroad, an export represents individual profit which he receives by the process of exchange. The individual act of exportation made for personal gain is, however, of the greatest national and public importance. Few countries produce all the commodities they require for their convenient existence, and to obtain from abroad articles which are not produced at home it is necessary to pay for them in an acceptable way. Hence the function of exportation, which from the national point of view represents payment for importation. For a full discussion of the subject and for the statistical records of exportation reference should be made to the articles Commerce and Export Statistics, and to the economic details appended to the articles on each of the different nations.

The exportation from a nation may take the form of goods, services or securities. The Custom Houses of all nations take records of the goods sent out, and these are compiled as national statistics showing values and sometimes quantities also. These statistics form a valuable record of national progress. The exportation of services and securities is not precisely recorded, but estimates have been formed for some nations from time to time. Because the exports of services do not appear in the trade accounts published by the nations, they are sometimes called "invisible exports," a term invented by the late Sir Robert Giffen. For further particulars of invisible exports, reference should be made to the article Balance of Trade. (L. C. M.)

EXPORTS IN PRACTICE

The very extensively organized machinery and methods employed in export trade have been evolved in the course of centuries to enable a trader in one country to sell to, or buy from, a trader in another country. The enabling process has consisted mainly in overcoming difficulties created by space and time in regard to selling, buying, distribution and methods of payment and credit. There are two principals to an export transaction, though neither need have definite knowledge of the other. One is the manufacturer, producer or factor with goods to export; the other is the wholesale distributor in the importing country. Between them exists the export machine consisting of various intermediaries and services, by means of which buyers can maintain effective touch with all sources of supply, while manufacturers are enabled to supply in many scattered markets the needs of customers whom they would never otherwise reach, whose requirements they could never discover, and whose credentials they could not test. The machine performs this comprehensive task by co-ordinating three distinct lines of effort, the first of which is selling, buying and distribution, the second transport by rail and steamship, and the third finance and insurance.

Two Basic Export Systems.—For selling, buying and distributing two different, yet parallel, systems are employed. One is more closely identified with British practice, and the other with American, though neither is a national monopoly. The broad difference between the two is that under the British system the manufacturer's immediate customers are merchant-shippers or commission buying agents established at his door, who accept all financial responsibility for the orders they place in fulfilment of indents received from their importing clients overseas; while under the American system the intermediaries are commission selling houses acting on behalf of groups of manufacturers, and combining the functions of merchant-shippers and sales representatives. Even these two systems leave some gaps, particularly in regard to certain markets which lack wholesale distributing firms of sufficient importance or which present credit difficulties of an exceptional nature. Such territories often fail to attract the enterprise of selling organizations, whose energies are absorbed by safer and larger markets; while the same drawbacks render commission buying agents in London, Paris or New York unwilling to assume responsibility for traders in countries which lack sound or comprehensive importing systems. In these relatively few cases, the manufacturer or shipper desiring to do business with the countries concerned has to devise special and more or less direct methods, safeguarding himself as well as he can by such devices as the *del credere* agency system, which has for years been used considerably in Egypt, and under which a local agent undertakes financial responsibility for the orders he forwards, and is remunerated by a correspondingly higher rate of commission.

The Merchant-Shipper.—The merchant-shipper and the commission buying agent exist side by side, and in modern times their duties have become so closely related as to be in part identical. The former is an independent trader, definitely a middleman, taking such profit as he can make, initiating his own selling efforts abroad, and acting as a principal toward his customers. He is the heir of a system as old as civilization itself, but changing conditions have compelled him to change with them. Whereas he once had the entire world to serve, in the 19th century he was confronted by the growth of a new order of things. Among his customers in such markets as the principal British dominions, the South American republics, and similar progressive countries, were many importing houses whose turnover became so extensive that

they were in a position to go direct to manufacturers, and to perform for themselves the duties previously undertaken for them by merchant-shippers. In many cases, too, these importers were urged to this change by the competition of great trading companies with headquarters in Europe, and widely distributed branches or stations. They therefore established their own buying and shipping houses in supplying centres, or appointed agents to act for them. The merchant-shipper thus found his scope becoming more and more limited, with—apart from certain special lines of business—only undeveloped markets, and the smaller importing accounts in the larger markets, offering him business on the old lines. Consequently, he has to an increasing extent been compelled to combine the work of commission buying with his more independent shipping operations.

The Commission Buying Agent.—Under the commission buying system an agent may act for a number of overseas importing firms, usually confined to only one or two markets. The procedure is for them to indent on him, an indent being an instruction to buy certain goods, and is not in itself an order. The agent acts on this instruction, buying the goods on quotations obtained from various manufacturers, arranging for their packing and shipment, and paying the accounts of manufacturers and ship-owners, for which he makes himself directly responsible. For these services he receives a commission on the amount of his purchases, the average rate being $2\frac{1}{2}\%$, though it may vary according to the nature of the goods bought. He usually undertakes to pass all discounts and rebates to the importers for whom he buys.

The Commission Selling Agent.—With the commission buying system so strongly entrenched, the export selling agency has not found much room for development in Great Britain, nor in certain European countries, but in the United States of America and in Canada it largely prevails. Its advantage lies in its active efficiency as a selling force on behalf of manufacturers; its principal defect lies in the virtual impossibility for a single concern to have a sufficiently expert and intimate acquaintance with buyers in all markets, to be able to arrange credits safely, or to cover the ground with adequate selling effort. In practice a certain amount of specialization occurs from necessity rather than intention. An export selling house may be formed as the result of a number of manufacturers of allied goods combining for the purpose, or an independent agency firm may obtain the sole right to sell on commission abroad the goods of a similar series of manufacturers. Such a concern despatches salesmen to obtain orders from wholesale buyers in selected markets, often establishing branches and showrooms in suitable centres, and attends to details of shipment, payments and credits, etc., on behalf of its principals.

The Manufacturer's Export Department.—Under the merchant-shipping and commission buying systems it is clear that no selling force operates on behalf of the manufacturer, and he is therefore compelled to provide his own. He begins, probably, by employing a special representative to solicit orders from the buying houses who are in receipt of indents for his class of goods. Some members of his counting-house staff will also specialize in knowledge of shippers' requirements in connection with shipping and customs documents. Then the need will become apparent for getting particular brands and designs specified in the indents sent home by overseas importers, or it will prove advisable to find further methods of stimulating business, so commission agents travelling in the markets served will be employed. Such agents usually represent a number of manufacturers, confine themselves to one market or group of markets, and call only on wholesale importers. Their mission is not to accept orders direct, but to persuade importers to specify certain goods and quantities when indenting on the commission buyers. The manufacturer is informed by his agent concerning each promised order, and then seeks confirmation of it from the buying house concerned. The agent is paid commission on all the orders received for shipment to the territory covered by him, and frequently obtains in addition a contribution toward his expenses from each of the manufacturers he represents. An alternative method is to employ an export agent who has headquarters in the supplying country, and who performs the entire work of sending representatives abroad and obtaining confirmation of the indents they influence.

In a few special trades, of course, and in a few specially conditioned markets, it is possible for the manufacturer to solicit orders directly, and to ship the goods without the intervention of any intermediaries. On the whole, however, direct export trading of this kind is regarded as inexpedient, and even dangerous, for it carries none of the safeguards which form an essential feature of the recognized systems described. In general trade, too, it is obvious that the direct shipper is almost certain to be barred from participating in the overwhelmingly preponderant proportion of shipments controlled by merchant-shippers and agents, and must, on adopting such a policy, recognize that the range of his possible clientèle will be severely limited.

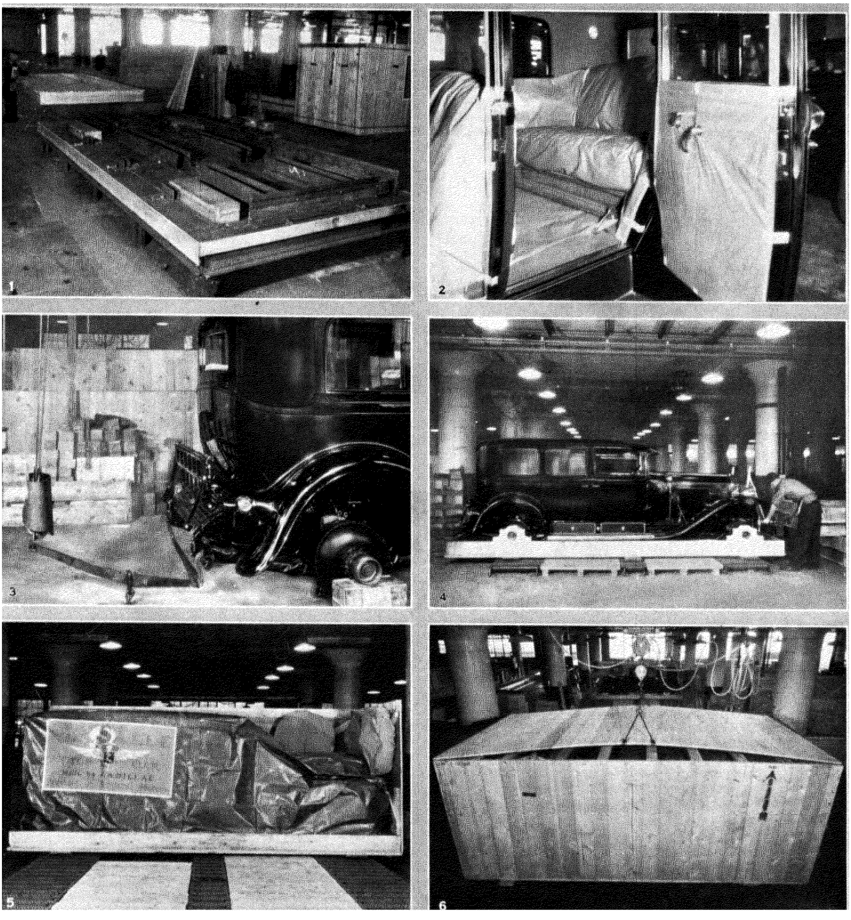
Shipping Methods, Finance and Insurance.—The actual work of shipping is the same if performed either by manufacturer, merchant-shipper or commission agent. It involves the arrangement of freight with shipowners, packing, carriage to the docks, and perhaps forwarding from an inland centre, the preparation of consular invoices and customs declarations, the receipt and mailing of shipping documents, possibly the hypothecation of the latter, and the insurance of the consignment.

Packing for Shipment.—This is a matter beset with special requirements for different markets, and even for different consignees. So far as these are concerned, the instructions of the indentor can be the only guide apart from knowledge of a prevailing custom. Goods are baled or cased according to their nature, baling being the cheaper, and the first step in either method is "making-up" or "knocking-down," the former term covering the folding, marking and ticketing of textiles, and the latter the separation into convenient parts of certain types of furniture, or the dismounting of machinery. The goods are then arranged in compact lots for measurement, and the case or baling material prepared to suit. If this work is done by a specialist packing firm, full instructions must accompany the goods, which should be inspected by the shipper when ready to close down. Marking is done in large stencilled letters, the consignee's "mark" and port of destination being placed on at least two sides of each package. The bales or cases are then handed over to a carrier for transport to the docks, where they are weighed or measured, and a "weight note" is handed to the carrier, this constituting in some circumstances a certificate of delivery, and even going forward with the shipping documents.

Shipping.—Before this stage is reached the shipper arranges freight with a shipowner or shipping company. For a special cargo it may be necessary to charter a vessel, and for this a charter-party is prepared. This document provides on the one side that the ship shall be seaworthy, properly equipped and waiting at the specified port by a certain date; while the charterer agrees to load promptly, pay the charges due, and use the vessel for a definite voyage, or as he desires during a definite period.

The general shipper, however, simply arranges for freight-space on a ship sailing with other cargo on a convenient date. He does this at a fixed or agreed rate per ton, the shipowner retaining the right to charge on ton-weight or ton-measurement, the latter being 40cu.ft. per ton, and used for light or bulky goods. To the carrying rate is added "primage," a charge for the use of the ship's cargo-handling machinery. "Primage and average accustomed" indicates a *pro rata* charge on each consignor. On embarkation a "mate's receipt" is obtained, and this is exchanged later for a bill of lading, which details the goods shipped and constitutes proof of ownership. The bill of lading is made out in several "parts" or copies, one of which is sent to the consignee by an earlier or faster vessel, so that he may obtain prompt delivery of the goods on arrival. The first "part" of a bill of lading to be presented is the only effective one, the others automatically becoming of no effect. It should be understood that if a bill of lading is made "to order," and not in a particular consignee's name, it must be endorsed by the shipper before it becomes valid.

Freight Terms.—Closely connected with the question of freight rates is that of quoting prices for export, as manufacturing costs and shipping charges obviously have to be joined at some point before the consumer of the goods is reached. There is a



BY COURTESY OF THE GENERAL MOTORS EXPORT CO.

PACKING FINE MOTOR CARS FOR FOREIGN MARKETS

1. A modern jig or pattern frame in the boxing factory of an automobile plant. Bottom of case is built around sections of frame shown
2. Interior view of closed car packed for export shipment. Upholstery is protected from dust and moisture by waterproof oiled-paper cover
3. Equipment used for compressing rear springs of cars to prevent up-and-down movement of car in the case. When springs are sufficiently compressed, they are clamped to fix them firmly in the case
4. Base of shipping case, showing car resting on axle blocks. Wheels are removed and holes are drilled for lag screws to hold the axles in place. The car is carried to location by overhead monorail conveyor; from location by roller conveyor seen below the case
5. Car unit completely wrapped in specially prepared oiled paper, ready for boxing in export case. Besides the paper envelope on car, the case is lined with heavy paper, water and vermin proof. Wheels are packed separately and bolted inside case. Roller conveyor is seen beneath case
6. Packing case complete, with lid lifted to show 4x4 timbers placed under the top to prevent injury to the car from the cases piled above it in transit

multitude of terms, each with some interesting variation of meaning, but the two basic methods of quoting are "Free on Board" and "Customs, Insurance and Freight," usually indicated as "F.O.B." and "C.I.F." The former covers all charges from the factory to loading and stowing in the ship's hold; the latter covers all costs to the port of delivery, but not such items as import dues and carriage after unloading. A "C.I.F." quotation is obviously more convenient to the importer, but it should be understood that it does not alter the fact that the shipper's ownership ends, and the consignee's begins, when goods are placed on shipboard. In arranging or paying any charges beyond that point the shipper is merely acting as agent for the consignee. Incidentally, freight becomes payable on arrival of the vessel at the port of destination, the shipper being legally liable for it to the shipowner, but having power of recovery from the consignee.

Marine Insurance.—The fact that ownership in a consignment rests in the consignee from the moment of shipment makes it necessary for any insurance policy to be taken out in his name, the shipper again doing this as his agent. On this subject it is sufficient to say that there are two principal classes of risks. One is "With Particular Average," which covers all risks, including damage and loss by disaster to the vessel, by exposure to heat or water, and by rough handling or accident. The second is "Free of Particular Average," and is limited to total loss, being usually adopted to cover rough goods, such as timber. "General Average" is another term referring to loss or charges incurred in preserving the vessel or cargo and involves a *pro rata* payment by all consignees.

Export Finance.—This is a wide subject, but in severe summary it may be explained that a shipper can reasonably well ensure payment from a customer overseas after shipping goods, and can also avoid having large sums lying idle, by a suitable use of bills of exchange in conjunction with shipping documents. He draws a bill of exchange on the customer, and forwards it to him for acceptance. He may draw "on demand" or "at sight," or he may draw at any given period "after sight" or "after date." On receiving it back "accepted" he can give it to a bank to collect, accompanied by the bill of lading and other documents necessary for obtaining delivery of the goods. The acceptor, if the bill is "at sight," is given the shipping documents on meeting the bill, this being done by the bank's local branch or agent. Like the bill of lading, the bill of exchange is also drawn in several parts, the first to reach the drawee being the one on which he writes his acceptance, and it becomes the "first of exchange." According to the state of the bill market, a shipper can usually take unmatured bills to a bank or discounting house, and obtain an advance against them. He may also do this when giving the bills to a bank to collect as described above, the shipping documents being the security. (*See* also EXCHANGE, FOREIGN; IMPORTING; INTERNATIONAL PAYMENTS; INSURANCE: *Marine.*)

BIBLIOGRAPHY.—F. M. Dudeney, *The Exporter's Handbook and Glossary* (1914), *How to Export Goods* (1922); W. F. Wyman, *Export Merchandising* (1922), an American point of view; A. Calvert, *Shipping Office Organization, Management and Accounts* (1926); W. F. Spalding, *The Finance of Foreign Trade* (1926); J. A. Dunnage, *Manual of Exporting* (1928). (F. M. D.)

EXPORTS, INVISIBLE. While, broadly speaking, it is true that imports must always be paid for by exports and vice versa, this payment is not always made in actual physical goods or bullion and specie. Other factors play their part in the balance sheet of a country's financial and commercial condition, and those which fill an economic rôle similar to exports are known as "invisible exports."

Among the more important of such factors which can thus be offset against imports are the following: (1) earnings of national ships in the trade of foreign countries; (2) disbursements of foreign shipping in national ports for harbour dues, bunker coal and other stores, repairs, etc.; (3) expenditure of foreign tourists in the country; (4) emigrants' remittances to friends and relations in the country; (5) loans raised abroad; (6) receipts on account of interest on or amortisation of national capital invested abroad; (7) commissions, royalties, brokerage, etc., earned by nationals for services rendered to foreigners (insurance, etc.); (8) government receipts from overseas (including repayment of and interest on loans by the national government to foreign governments).

In some cases separation is made between items which may be termed "revenue" (as interest, earnings, etc.) and those which are of a "capital" nature (as repayment of loans, loans raised abroad), while in some cases "revenue" items only are taken into account.

While it is impossible to make exact calculations as to the value of many of these items, governments are usually in a position to make estimates as to the approximate magnitude of some or all of the various factors which operate in balancing the economic situation of their countries; in some cases, however, the task of making—or at least of publishing—such an estimate is left to a financial institution or economic journal. In some cases, only the balance after deducting the corresponding "invisible imports" items is published.

Great Britain.—The economic balance sheet for the United Kingdom is prepared and published by the Board of Trade early in the ensuing year in the *Board of Trade Journal* under the caption "The Balance of Trade." This estimate is of a provisional nature, and is accompanied by a revision of the figures for the previous year or years, in the view of more complete information which has since become available, and brief notes as to the basis of the estimates used. The published figures relate only to balances after deducting the corresponding "import" items, and (except as regards Government expenditure and receipts) to "revenue" transactions only.

The following table from the *Journal* for Feb. 2, 1928, gives the figures (together with the revised figures for 1925 and 1926) so far as "export" items are concerned.

	1925.	1926.	1927.
	(In million £.)		
Estimated excess of Government receipts from overseas*	..	3	..
Estimated net national shipping income†	124	120	140
Estimated net income from overseas investments	250	270	270
Estimated net receipts from short interest and commissions	60	60	63
Estimated net receipts from other services	15	15	15
Total	449	468	488

*Including some items on loan account.
†Including disbursements by foreign ships in British ports.

United States.—A statement entitled "The Balance of International Payments of the United States" is published annually by the Department of Commerce in its *Trade Information Bulletin* series which gives considerable detail and discussion under the

†Estimate not made.

various sections. The American estimates deal with both "revenue" and "capital" items, but they are distinguished throughout. In addition to the usual items referred to above, an investigation is also made in the change in foreigners' bank deposits and book accounts, and the figure thus arrived at should, of course, represent the balance of the statistical calculation. The small discrepancy which appears (less than ½% of the total sums involved) represents the margin of error in the estimates.

The table on p. 995 from the *Bulletin* No. 503 gives the summary so far as "export" items are concerned.

Other Countries.—Statements or estimates of a similar nature in respect of a number of other countries are published by the League of Nations in its *Memorandum on International Trade and Balances of Payments.* (H. Cr.)

EXPORTS: STATISTICS. The following tables give an account of the recorded official export statistics of the chief exporting nations. In comparing them, it should be remembered that different nations make their records in very different ways and this has been made clear as far as possible in the notes attached to the tables, which should be carefully read.

UNITED KINGDOM

The following statistics relate to Exports of United Kingdom produce and manufacture only.

The grouping into categories in the published returns was entirely re-cast in 1920, but figures for 1913 were republished on the revised grouping.

(A) *Old Classification*

	1891†	1900	1913
	Thousand £	Thousand £	Thousand £
I. Food, drink and tobacco*	9,996	14,049	32,588
II. Raw materials and articles mainly unmanufactured	24,512	44,987	69,905
III. Articles wholly or mainly manufactured‡	211,071	228,302	411,368
IV. Miscellaneous and unclassified (including parcel post)	1,656	3,854	11,384
Total	247,235	291,192	525,245

(B) *New Classification*

	1913	1927
	Thousand £	Thousand £
I. Food, drink and tobacco*	33,876	52,280
II. Raw materials and articles mainly unmanufactured	66,173	76,356
III. Articles wholly or mainly manufactured‡	413,821	563,964
IV. Animals, not for food	2,230	1,897
V. Parcel post	9,154	14,608
Total	525,254**	709,105

Total exports for 1928 were valued at £723,000,000.

*Including animals for food: in 1900, these animals were not separated from those not for food and all animals were grouped in Class IV. in that year. The two classifications differ in that oil seed cake and other feeding stuffs for animals are now grouped in I. instead of III. as formerly, and Bladders and Sausage Skins in I. instead of II.

†1891 was the earliest year for which this summary was published, although somewhat similar summaries—without details—were published back to 1883.

‡Including Crude Metals. The old classification excludes Coke, Patent Fuel and refined mineral oils (included in II.) but includes Coal Tar Pitch (now in II.). There are also minor adjustments between II. and III.

**In the new classification British and Foreign Spirits mixed in bond and Lime Juice fortified in Bond, previously classed as re-exports, are included in British Exports.

DOMINION OF CANADA

The following particulars relate to the Exports of the Produce and Manufactures of the Dominion, including Gold and Silver, the direct product of the Mining Industry. The values are those at the point in Canada at which shipped, as declared by exporters.

	Year ended June 30		Year ended March 31	
	1891†	1900	1914	1927
	Thousand $	Thousand $	Thousand $	Thousand $
I. Agricultural and vegetable products:*				
(a) Mainly food	13,743	28,230	169,717	505,502
(b) Other than food)			31,473	69,492

VII. Non-metallic minerals	3,989	5,956	9,364	28,510
VIII. Chemicals	851	455	4,890	16,575
IX. Miscellaneous	5,291	8,824	5,731	18,077
Total	88,672	168,972	431,588	1,252,158

*Excluding fibres and wood. Beverages are included under I. (b).
†The earliest year for which this grouping is available.

UNION OF SOUTH AFRICA

The following particulars relate to Exports of South African Produce from the Union to countries overseas, and exclude exports to Northern and Southern Rhodesia (and in 1926 to S.W. Africa Protectorate). Gold Bullion is included, and also Bunker Coal. The values shown represent f.o.b. values, as declared by exporters.

	1910*	1913	1926
	Thousand £	Thousand £	Thousand £
Living animals	42	38	24
Agricultural and pastoral produce	9,485	12,240	21,314

Other articles	240	430	1,393
Total	51,763	64,565	70,399

*Prior to 1910, particulars were only available for the separate provinces of the Union, including inter-trade.

AUSTRALIAN COMMONWEALTH

Particulars relate to exports of Australian produce only. The values shown represent values in the principal markets of the Commonwealth. Ships' stores are included in 1903 but not in subsequent years. Bullion and Specie are shown separately; they are included in total value of exports, since they are part of the produce of the soil of the Country.

	Year ended December 31		Year ended June 30,

Crude materials	309,482	340,139	740,290	1,174,251
Semi-manufactures	46,455	153,276	408,807	713,623
Finished manufactures	132,527	331,747	776,297	2,061,210
Total	845,294	1,370,764	2,428,506	4,772,865

*Including animals for food.

Note:—The above particulars include the trade of Hawaii, Porto Rico and Alaska with abroad, but exclude the trade between Continental U.S.A. and the non-contiguous territories and also Guam and Tutuila.

FRANCE

The following particulars relate to "Commerce Special," *i.e.*, exports of French Produce. The values for 1890, 1900 and 1913 are based on official unit values, fixed annually by the Permanent Valuation Commission, those for 1927 are as declared by exporters, in both cases, frontier (f.o.b.) values are intended. Bullion and Specie are excluded.

	1890	1900	1913	1927*
	1,000 Francs	1,000 Francs	1,000 Francs	1,000 Francs
Food and drink	855,378	769,159	838,898	5,384,383
Raw materials	899,036	1,084,784	1,858,091	16,780,531

Total	3,753,458	4,108,699	6,880,217	55,224,717

*Provisional figures, expressed in paper Francs.

†Including parcel post.

Note:—For 1927, the particulars relate to Post-war France (including Alsace Lorraine), and the Saar Basin.

GERMANY

The particulars relate to the German Customs Union (which included Luxemburg until 1919). The values for 1890 and 1900 are official values; those for 1913 and 1927 declared values; in both cases frontier (f.o.b.) values are intended. Bullion and Specie are excluded. Owing to a change in the form of the published figures, the particulars for 1913 have been shown according to both groupings.

	A. Old classification			B. New classification	
	1890	1900	1913	1913	1927*
	1,000,000 Marks	1,000,000 Marks	1,000,000 Marks	1,000,000 Marks	1,000,000 Marks

*1907 is the earliest year for which this table was published.

(H. Cr.)

EXPOSITION, a word of numerous applications. One of the most common is the theological, *i.e.*, the action of expounding, the explaining of a text. In *logic*, the word is used to indicate a "showing forth" of principles, a "statement" of the nature of things and their disposition. In its modern industrial application it is a synonym for exhibition (*q.v.*).

EX POST FACTO (lit. "from what is done afterwards"), a phrase used especially of laws operating retrospectively.

EXPRESS, a word signifying that which is clearly and definitely set forth or represented, explicit, and thus used of a meaning, a law, a contract, and the like, being specially contrasted with "implied." Thus in law, malice, for which there is actual evidence, as apart from that which may be inferred from the acts of the person charged, is known as "express." The word is most frequently used with the idea of something done with a definite purpose. The term "express train," which has become associated with the idea of speed, originally meant a train running for some specific purpose or engaged by a private person.

In the United States, express companies for the rapid transmission of parcels and luggage and light goods generally perform the function of the post office or the railways in Great Britain and the Continent of Europe. Not only do they deliver goods, but by the cash on delivery system (*see* Cash) they act as agents both for the purchaser and seller of goods. They also serve as a most efficient agency for the transmission of money, the express money order being much more easily convertible than the postal money order, as the latter can only be redeemed at offices in large towns. The system dates back to 1839, when one William Frederick Harnden (1813–45), a conductor on the Boston and Worcester railway, undertook on his own account the carrying of small parcels and the performance of small commissions. Obliged to leave the company's service or abandon his enterprise, he started an "express" service between Boston and New York, carrying parcels, executing commissions and collecting drafts and bills. Alvin Adams followed in 1840, also between Boston and New York. From 1840 to 1845 the system was adopted by many others between the more important towns throughout the States. The attempt to carry letters also was stopped by the Government as interfering with the post office. In 1854 began the amalgamation of many of the companies. Thus under the name of the Adams Express Company the services started by Harnden and Adams were consolidated. The lines connecting the west and east by Albany, Buffalo and the lakes were consolidated in the American Express Company, under the direction of William G. Fargo (*q.v.*), Henry Wells and Johnston Livingston, while another company, Wells, Fargo and Company, operated on the Pacific coast. The celebrated "Pony Express" was started in 1860 between San Francisco and St. Joseph, Mo., the time scheduled being eight days. The service was carried on by relays of horses, with stations 25m. apart. The charge made for the service was $2.50 per ½ ounce. The completion of the Pacific Telegraph Company line in 1861 was followed by the discontinuance of the regular service. In 1918 the several Express companies were brought under the control of a single company, the American Railway Express Company, which acted as agent for the U.S. Director of Railroads, in handling express matter on railroads placed under Government control. The Transportation Act of 1920 specifically permitted the American Railway Express Company to continue as a private organization after the Government returned the railroads to private owners, during that year. Thus, one company has since practically handled the entire express business of the country with 27,500 offices and 125,000 employes, and operating over 260,000 miles of railroad. In Sept. 1927 the Air Express was inaugurated. This is being expanded so that ultimately there will be a network of Air Express routes.

EXPRESSION OF THE EMOTIONS, the facial and other bodily changes which are the characteristic accompaniments of Emotion (*q.v.*). According to Darwin (in *Expression of the Emotions*) these expressions are survivals of actions which were once useful under conditions which induce the emotions. They are "serviceable associated habits." As this theory does not appear to account for all cases, it has been supplemented by various auxiliary hypotheses, of which the following are the most important. Experiences which induce like emotions express themselves in the same way, namely, in the once useful way of one of them. On the other hand, experiences which excite opposite emotions express themselves in opposite ways, assuming that one of them has an expression that was once useful. Some psychologists explain the expression of the emotions as a "direct nervous discharge" resulting in muscular activity; pleasurable emotions causing an increase in muscular activity, while painful ones inhibit it.

See Feeling, Psychology of; James-Lange Theory of Emotions.

EXPROPRIATION, the taking away or depriving of property. The term is particularly applied to the compulsory acquisition of private property by the State or other public authority. (*See* Compensation.)

EXPULSION, the act of removing a person from the membership of a body or the holding of an office, or of depriving him of the right of attending a meeting, etc. In Great Britain the House of Commons can by resolution expel a member. Such resolution cannot be questioned by any court of law. But expulsion is only resorted to in cases where members are guilty of offences which render them unfit for a seat in the House. It is customary first to order the member, if absent, to attend in his place, before an order is made for his expulsion. (*See* May, *Parliamentary Practice*, 1917, p. 61 *seq.*) Municipal corporations or other local government bodies have no express power to expel a member, except in such cases where the law declares the member to have vacated his seat, or where power is given by statute to declare the member's seat vacant. In the case of officers and servants of the Crown, tenure varies with the nature of the office. Some officials hold their offices *ad vitam aut culpam* or *dum bene se gesserunt*, others can be dismissed at any time and without reason assigned and without compensation. In the case of membership of a voluntary association (club, etc.) the right of expulsion depends upon the rules, and must be exercised in good faith. Courts of justice have jurisdiction to prevent the improper expulsion of the member of a voluntary association where that member has a right of property in the association. In the case of meetings, where the meeting is one of a public body, any person not a member of the body is entitled to be present only on sufferance, and may be expelled on a resolution of the body. In the case of ordinary public meetings those who convene the meeting stand in the position of licensors to those attending and may revoke the licence and expel any person who creates disorder, and by the Public Meeting Act 1908 any person acting in a disorderly way for the purpose of preventing the proceedings is liable to a penalty of £5 or to one month's imprisonment. (*See* Aliens; Nationality and Naturalization.)

EX-RIGHTS, without rights. Stock which is entitled to privileged subscription rights may be sold alone and the rights to subscribe to new stock retained by the seller. Such a sale is known as a sale "ex-rights." (*See* Rights.)

EXTEMPORIZATION, in music, is the art of inventing the music performed and performing it simultaneously, in the same way as an orator speaks *ex tempore* when he has no notes to aid him and frames his remarks spontaneously as he proceeds. The humblest amateur who strings a few chords

together is in the strict sense extemporizing, no less than the trained musician whose "profuse strains of unpremeditated art" take shape in complete and perfectly worked-out compositions. Truly marvellous were the performances in this way of some of the great masters of the past.

Thus of Bach we are told that his powers in this respect were absolutely unlimited—the inexhaustible flow of his invention being at the same time invariably combined with the most rigorous regard for form. Schweitzer tells us further concerning him that if he improvised for as long as two hours together on the organ the theme remained the same from beginning to end.

Handel's wonderful powers in this respect drew attention to him at a very early period of his career. And these powers he retained to the end of his days, so that in the case of his organ concertos it was his habit more often than not merely to sketch in the solo part, leaving it with serene confidence to the inspiration of the moment to supply all else that was required.

As for Mozart he excited amazement even as a child by his astonishing achievements under this head. Those were the days of the musical duello, in the shape of formal contests of skill between acknowledged masters, and many were the combats of this kind in which Mozart engaged.

And not less memorable were some of the contests of the same order in which Beethoven took part. In one which caused great stir his opponent was Steibelt, an arrogant virtuoso of the day, who professed nothing but contempt for his youthful and uncouth-looking opponent, but whose mortification was such as he listened to Beethoven's marvellous and inspired playing that he could finally stand it no longer and rushed out of the room.

As to Beethoven's improvisation in general, many eloquent accounts have been left by those who heard him. "His extemporization," said Czerny, "was most brilliant and striking. In whatever company he happened to be he knew how to produce such an effect upon his hearers that frequently not an eye remained dry while many would break out into loud sobs." Ries, in turn, recorded, "No artist that I ever heard came anywhere near the height which Beethoven attained in this branch of performance. The wealth of ideas which forced themselves on him, the caprices to which he surrendered, the variety of treatment, the difficulties, were inexhaustible."

Among more recent composers no one excelled more in this line, perhaps, than Mendelssohn, of whose extraordinary facility many astonishing stories are told—as, for instance, that of the famous three cadenzas which he introduced when playing Beethoven's G major piano concerto with the London Philharmonic Society—the first two at rehearsal and the third, totally different from either of its predecessors, at the concert itself. Yet, his great facility notwithstanding, Mendelssohn extemporized in public with reluctance and in one of his letters even went the length of registering the determination never to perform in that way again. Did he feel, perhaps, acutely sensitive as he was, that the public listened to such performances more as feats of wonder than for the music which they heard, and so came to resent this showman-like exhibition of his powers?

Four-handed improvisation, that is, by two players together, was also sometimes practised in earlier days—as by Clementi and Mozart, by Beethoven and Wölfl and by Mendelssohn and Moscheles. Needless to say this called for the highest skill.

Extemporization of another kind was that required in supplying the embellishments and other details of a composition which were formerly left to the taste of the performer. Of such details the cadenza, or special passage for the display of the soloist's powers, in instrumental concertos is nowadays the sole surviving example, and even this in only a nominal sense. For in modern concertos the cadenzas are almost invariably provided by the composer, or if still entrusted to the soloist are assuredly never left in these days to the hazard of improvisation but are carefully prepared and rehearsed beforehand. (H. A. Sc.)

EXTENDED ORDER, a formation in which the men composing a body of troops, and the various smaller component units, are opened out with intervals between them, so as to afford a more difficult target and minimize the effects of enemy rifle or shell fire. The power of modern weapons is such that all movements on the battlefield within sight or range of an enemy must of necessity be carried out in extended order, if heavy casualties are not to be incurred and further progress to become impossible. (*See* further INFANTRY.)

EXTENSION, the action of straining or stretching out (Lat. *ex*, out; *tendere*, to stretch) (*see* ELASTICITY). It is usually employed metaphorically (*cf.* the phrase an "extension of time," a period allowed in excess of what has been agreed upon). It is used as a technical term in logic to describe the objects or kinds of objects to which a given term may be applied; thus the meaning of the term "King" in "extension" means the kings of England, Italy, Spain, etc. (*cf.* DENOTATION), while its "intension" consists of the qualities or attributes which are suggested by the term king (*see* CONNOTATION). In psychology the literal sense of extension is retained, *i.e.*, "spread-outness." The perception of space by the senses of sight and touch, as opposed to semi-spatial perceptions by smell and hearing, is that of "continuous expanse composed of positions separated and connected by distances" (Stout); to this the term "extension" is applied. The perception of separate objects involves position and distance, but these taken together are not extension, which necessarily implies continuity. To move one's finger along the keys of a piano gives both the position and the distance of the keys; to move it along the frame gives the idea of extension. By expanding this idea we obtain the conception of all space as an extended whole. To this perception are necessary both form and matter. It should be observed that the actual quality of a stimulus (rough, smooth, dry, etc.) has nothing to do with the spatial perception as such, which is concerned purely with what is known as "local signature." The elementary undifferentiated sensation excited by the stimuli exerted by a continuous whole is known as its "extensive quantity" or "extensity." The term has to do not with the kind of object which excites the sensation, but simply with the vague massiveness of the latter. As such it is distinguishable in thought from extension, though it is not easy to say whether and if so how far the quantitative aspect of space can exist apart from spatial order. Extensity as an element in the complex of extension must be carefully distinguished from intensity. Mere increase of pressure implies increase of intensity of sensation; to increase the extensity, the *area*, so to speak, of the exciting stimulus must be increased. Thus the extensity (also called "voluminousness," or "massiveness") of the sensation produced by a roll of thunder is greater than that produced by a whistle or the bark of a dog. It should be observed that this application of the idea of extensity to sensation in general, rather than to the matter which is the exciting stimulus, is only an analogy, an attempt to explain a common psychic phenomenon by terminology which is intrinsically suitable to the physical. As a natural consequence the term represents different shades of meaning in different treatises, leaning sometimes towards the physical, sometimes towards the psychic, meaning.

In connection with extension elaborate psycho-physical experiments have been devised, *e.g.*, with the object of comparing the accuracy of tactual and visual perception and discovering what are the least differences which each can observe. At a distance two lights appear as one, just as two stars distinguishable through a telescope are one to the naked eye (*see* VISION): again, if the points of a compass are brought close together and pressed lightly on the skin the sensation, though vague and diffused, is a single one.

See PSYCHOLOGY and works there quoted; also SPACE AND TIME.

EXTENUATING CIRCUMSTANCES. This expression is used in law with reference to crimes, to describe cases in which, though an offence has been committed, its gravity is mitigated or reduced by reason of facts attending the commission of the offence. It is common practice for juries to add to their verdict a rider recommending the accused to mercy on the ground of circumstances which in their view should mitigate the penalty. In case of a wilful murder, a crime as to which the judge has no discretion as to punishment, the recommendation is sent to the Home Office for consideration in advising as to exercise of the prerogative of mercy.

Under the French law it is the sole right and the duty of a jury in a criminal case to pronounce whether or not the commission of the offence was attended by extenuating circumstances. When the whole or the majority qualify the verdict by finding extenuation the powers of the court to impose the maximum punishment are taken away and the sentence to be pronounced is reduced in accordance with the scale laid down in art. 463 of the *Code pénal*. The most important result of this rule is to enable a jury to prevent the infliction of capital punishment for murder.

EXTERRITORIALITY, a convenient term or metaphor for the immunities enjoyed by certain persons, property or places from the jurisdiction of the State in which they are situate.

Persons and Property.—In most systems of law, including that of England, foreign sovereigns and titular heads of States are exempt from the local jurisdiction (even if travelling incognito) not merely for acts done in their sovereign, but also for acts done in their private, capacity. The same immunity extends to their property and would appear to extend to members of their family and suite. The English courts, however, assume jurisdiction over the person or property of a sovereign where (a) he has instituted proceedings or has voluntarily submitted to the jurisdiction; (b) property in which he is interested and which is subject to some equitable claim is found in the hands of a private person or corporation over whom the court has jurisdiction; (c) he is a subject of the Crown; (d) he is owner of immovable property. It is commonly stated that foreign sovereigns are exempt not only from civil but also from criminal jurisdiction. There does not appear to be any support for this proposition in English law. On the contrary, when Mary of Scotland claimed her immunity as a sovereign, Sir Christopher Hatton L.C. replied "You say you are a queen; be it so. But in such a crime the royal dignity is not exempted from answering, neither by the civil nor canon law, nor by the law of nations." And Sir Robert Phillimore stated that if a sovereign abused the hospitality, or committed an offence against the welfare, of the country in which he is a guest, the authorities would by international law be justified in placing him under arrest, and that if he perished in resisting such restraint, no maxim of international law is violated. Further it is at any rate clear that there is no rule or custom of international law exempting from criminal jurisdiction a foreign sovereign who has invaded the territory of another sovereign and committed an offence therein. Diplomatic agents representing heads of States enjoy similar immunities, which are also extended, so far as they are applicable, to members of their families and persons in their fixed service. They are also exempt from taxation and from custom duties on articles imported for their personal use. They retain the domicile of their own country and their children born within the embassy or legation acquire their domicile and nationality. Whilst it is said that they cannot be tried for a criminal offence and cannot as a rule be arrested, many jurists agree that they are not wholly free from the local jurisdiction in respect of crime committed by them whether against individuals or the State. If the offence is serious and urgent there is no doubt they may be arrested and retained in custody pending redress by their State, or for other reasons. In spite of the statute of Anne 1708, which provides that all writs and processes which may be sued or prosecuted whereby an ambassador or minister or their domestic servants are arrested or imprisoned or their goods detained, shall be null and void, Count Gyllenborge, the Swedish ambassador, was arrested and kept in custody in 1717 for treason. It would appear, therefore, that the statute only refers to civil jurisdiction. And in 1718 Prince Collemare, the Spanish ambassador in Paris, was arrested for a similar offence, and detained until the return of the French ambassador from Madrid. Such measures, says W. E. Hall, may be justified on the ground that the ambassador of a friendly power must *prima facie* be supposed to be exceeding his instructions in doing acts inimical to the Government to which he is accredited. Nor is he wholly exempt from civil jurisdiction. Such jurisdiction extends to property real or personal held by him as an owner, trustee or trader. He is free from all forms of taxation, but not from local rates unless by mutual arrangement. The position of the military forces of one State within the territory of another State with which it is in amity is similar to that of public vessels in territorial waters.

Places.—The residence of a diplomatic agent and its precincts are exempt from the local jurisdiction so far only as to secure the free exercise of his functions. Thus, where the safety of the State or public order is involved, entry may be made by the local authorities, papers may be searched and persons arrested, whether they are the minister himself, or members of his staff or retinue, or political refugees or criminals. But where the local sovereignty is in abeyance or unable to act owing to local disturbances or civil war, legations, like any other body, may grant asylum. In some non-Christian countries, *e.g.*, Turkey, Egypt, Japan, Morocco, Muscat, Persia, China, Korea and Siam, communities have been established consisting of persons who, whilst resident in certain areas, are deemed for the purposes of civil and criminal jurisdiction to be extra-territorial and subject only to their respective national laws administered by their respective consuls or other authorities appointed by their respective Governments. Such communities have been established by capitulations or treaties. In such communities the consulates are regarded as exterritorial and the consuls themselves enjoy diplomatic immunities. Public vessels in the ports or territorial waters of a friendly Power, the crew and persons on board, and all property thereon are also exempt from the local jurisdiction. Private vessels, however, are not exempt, and legal processes may be served and arrests effected on board. Persons born on board a British vessel wherever situated or in an exterritorial community are natural-born British subjects (*see* NATIONALITY). An instance of immunity is that granted to the pope by the Italian Law of Papal Guarantees, 1871.

(H. H. L. B.)

EXTORTION, in English law the term applied to the exaction by public officers of money or money's worth not due at all, or in excess of what is due, or before it is due. Such exaction, unless made in good faith (*i.e.*, in honest mistake as to the sum properly payable), is a misdemeanour by the common law and is punishable by fine and (or) imprisonment. Besides the punishment above stated, an action for twice the value of the thing extorted lies against officers of the king (1275, 3 Edw. I. c. 26). There are numerous provisions for the punishment of particular officers who make illegal exactions or take illegal fees; *e.g.*, sheriffs and their officers (Sheriffs Act, 1887), county court bailiffs (County Courts Act, 1888), clerks of courts of justice, and gaolers who exact fees from prisoners. A gaoler is also punishable for detaining the corpse of a prisoner as security for debt. The term "public officer" is not limited to offices under the Crown; and there are old precedents of criminal proceedings for extortion against churchwardens, and against millers and ferrymen who demand excessive tolls.

The term extortion is also applied to the exaction of money or money's worth by menaces of personal violence or by threats to accuse of crime or to publish defamatory matter about another person. These offences fall partly under the head of robbery and partly under blackmail (*q.v.*).

EXTRACT, in pharmacy, the name given to preparations formed by evaporating or concentrating solutions of active principles; *tinctures* are solutions which have not been subjected to any evaporation. "Liquid extracts" are those of a syrupy consistency, and are generally prepared by treating the drug with the solvent and causing the solution to be concentrated until it attains the desired consistency. "Ordinary extracts" are thick, tenacious and sometimes even dry preparations.
